both in humans and in animals. When applied to the skin of rabbits, a concentration of 20 g/kg caused death in 50 percent of the animals (RTECS 1991). The oral LD50 in rats is 8470 mg/kg, and the LCso in the same species is 162 g/m3 (RTECS 1991). Instillation of the liquid into the eyes of rabbits caused minor injury, and repeated skin contact caused dermatitis in rabbits (Proctor, Hughes, and Fischman 1988, p. 293). Experimental animals surviving nearlethal exposures showed severe liver damage at autopsy (HSDB 1990). Animal studies have also shown that exposures to high concentrations of isopropyl ether cause narcosis and death (Machle, Scott, and Treon 1939/ Ex. 1-348). Experimental animals (a monkey, a rabbit, and a guinea pig) survived a onehour exposure to a 30,000-ppm concentration, although they manifested signs of narcosis during the exposure (Proctor, Hughes, and Fischman 1988, p. 293). Twenty exposures to a 1-percent vapor concentration (i.e., to a 10,000ppm concentration) produced systemic intoxication and central nervous system depression but no significant blood or organ weight changes [Machle, Scott, and Treon 1939/Ex. 1-348).

Human volunteers exposed for 15 minutes to isopropyl ether concentrations of 300 ppm experienced no overt irritation but complained about the objectionable odor of this substance; however, eye and nose irritation did occur during a 5-minute exposure to an 800-ppm concentration; some volunteers also experienced upper respiratory tract irritation at this concentration.

Based on this evidence, OSHA is proposing a 500 ppm 8-hour TWA limit for isopropyl ether in agricultural workplaces. The Agency preliminary concludes that this limit is necessary to substantially reduce a significant risk among agricultural workers of sensory irritation.

LITHIUM HYDRIDE CAS: 7580-67-8; Chemical Formula: LiH H.S. No. 2101

OSHA's PEL for lithium hydride in general industry, construction, and maritime is 0.025 mg/m³ as an 8-hour TWA; there is no PEL in agriculture. The ACGIH TLV*-TWA for lithium hydride is 0.025 mg/m³; there is no NIOSH REL. OSHA is proposing an 8-hour TWA PEL of 0.025 mg/m³ for lithium hydride in agriculture. This is the limit recently established for this substance in general industry.

Pure lithium hydride is an odorless, white, crystalline solid that is pyrophoric and darkens on exposure to light. The commercial product is a bluish-gray solid. Lithium hydride is used as a reducing and condensing agent, a desiccant, and as an intermediate in chemical synthesis. It is also used in hydrogen generators, in nuclear shielding material, in the manufacture of electronic tubes and ceramics, and in space technology (HSDB 1985; ACGIH 1986; Gosselin, Smith, and Hodge 1984, p. II–105).

Lithium hydride is severely irritating and corrosive to the eyes, mucous membranes, skin, and respiratory tract of both animals and humans. The lowest lethal concentration in rats is 10 mg/m3 for 4 hours; acutely poisoned animals showed pulmonary edema at autopsy (RTECS 1991). Rabbits exposed to a 5mg/m3 concentration showed signs of eye irritation (RTECS 1991). Single acute exposures of animals to lithium hydride concentrations ranging from 5 to 55 mg/ m3 caused respiratory tract irritation in all species and at all concentrations (Browning 1969). Exposure to a 10-mg/ m3 concentration caused corrosion of body fur and the skin of the legs and severe inflammation of the eyes and nasal septum (Browning 1969). Animals exposed 4 hours/day to a 5-mg/m3 concentration of lithium hydride for a period of 1 week exhibited coughing, sneezing, dyspnea, and signs of emphysema. However, no exposurerelated lesions were noted in the lungs. liver, trachea, lymph nodes, or kidneys of these animals at autopsy (Browning

A technician working in the vicinity of a cylinder of lithium hydride that exploded had eye contact with some of the material and swallowed a small amount of the dust. The exposure resulted in burns that scarred both corneas and in strictures of the larynx, trachea, bronchi, and esophagus; death occurred 10 months later (Cracovaner 1964). A few milliequivalents of the lithium ion in the plasma can cause anorexia, nausea, tremor, muscle twitches, apathy, confusion, visual disturbances, coma, and death (Goodman and Gilman 1955). A lithium hydride concentration of 0.05 mg/m3 is objectionable to some exposed individuals, and exposure to a 0.1-mg/ m3 concentration causes eye and nose irritation (AIHA 1964).

Based on this evidence in humans and animals, OSHA preliminarily concludes that agricultural workers exposed to this substance at the levels permitted by the absence of a permissible exposure limit are at significant risk of experiencing severe irritation of the eyes, skin, mucous membranes, and respiratory tract. The Agency believes that establishing a PEL of 0.025 mg/m³ as an

8-hour TWA will protect workers in agriculture from these significant risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

MALEIC ANHYDRIDE CAS: 108-31-6; Chemical Formula: C4H2O3

H.S. No. 2102

In general industry, construction, and maritime, OSHA's permissible exposure limit for maleic anhydride is 0.25 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV* of 0.25 ppm as an 8-hour TWA for this substance; NIOSH has no REL. OSHA is proposing an 8-hour TWA PEL of 0.25 ppm for maleic anhydride in agriculture. This is the limit recently established for this substance in general industry.

Maleic anhydride is a solid at room temperature and is colorless and crystalline in form. It is commercially available as briquettes, white lumps, tablets, and pellets. Maleic anhydride is used as a chemical intermediate, an ingredient in pesticides, a preservative for fats and oils, in paper sizing, in permanent press fabrics, in the manufacture of resins, and as a raw material for organic synthesis (ACGIH 1986, p. 359; AIHA 1978; HSDB 1987). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Maleic anhydride is both an eye, skin, and upper respiratory tract irritant and a skin and pulmonary sensitizer. The oral LD50 in rats is 400 mg/kg, and the dermal LD50 in rabbits is 2620 mg/kg (RTECS 1990). In contact with the skin or eyes, maleic anhydride causes severe irritation and caustic burns (Grant 1986, p. 574). Rats injected subcutaneously with 1 mg maleic anhydride twice/week for 61 weeks developed fibrosarcomas (Dickens and Jones 1963).

Because maleic anhydride hydrolyzes in contact with moisture to maleic acid. contact of the eyes, mucous membranes, or skin causes severe irritation and burns. Even at a concentration of 0.25 ppm, humans report experiencing irritation (AIHA 1969), but exposure to 0.22 ppm causes no irritation (Grigoreva 1966). Workers exposed to unspecified concentrations of the dust or vapors have developed punctate epithelial keratitis, but the eyes of these individuals have returned to normal within a few days of exposure (Ghezzi and Scotti 1965; Heersink and Dunne 1976; Kowalski and Slusarczyk-Zalobna et al. 1968). Workers exposed to unspecified concentrations of maleic

anhydride under conditions described as "uncontrolled" showed acute systemic effects that were manifested as respiratory, nervous, and cardiovascular system disorders (Titiova and Zakivova 1977). Chronic exposure to maleic anhydride may cause chronic conjunctivitis, keratitis, and bronchitis (AIHA 1969; Tanaka 1976). Repeated exposure to a 1.25 to 2.5 ppm concentration of this substance produced ulceration of the nasal septum and, in some workers, asthma (AIHA 1969). Repeated contact of the skin causes allergic dermatitis (AIHA 1969).

Based on this evidence in humans and animals, OSHA is proposing an 8-hour TWA PEL of 0.25 ppm for maleic anhydride in agriculture; adoption of the proposed level would establish the same PEL for workplaces in all OSHAregulated industry sectors. The Agency preliminarily concludes that occupational exposure to maleic anhydride causes irritation of the eyes, skin, and upper respiratory tract and pulmonary and skin sensitization. Accordingly, OSHA believes that, in the absence of a permissible exposure limit. workers in agriculture are potentially at significant risk for these exposurerelated effects and that the proposed PEL will substantially reduce these risks.

MESITYL OXIDE

CAS: 141-79-7; Chemical Formula:
[CH₃]₂C=CHCOCH₃

H.S. No. 1243

OSHA's limit for mesityl oxide in the construction and maritime industries is 25 ppm as an 8-hour TWA. The Agency has no PEL for this substance in agriculture. The ACGIH has a TLV*-TWA of 15 ppm and a TLV*-STEL of 25 ppm for mesityl oxide; the NIOSH REL is 10 ppm as a 10-hour TWA. OSHA is proposing a 15 ppm 8-hour TWA and a 25 ppm STEL for mesityl oxide in the construction, agriculture, and maritime industries. These are the limits recently established for mesityl oxide in general industry.

Mesityl oxide is an oily, colorless liquid with an odor similar to that of peppermint. It is used as an insect repellant, a paint remover, a solvent, and in ore flotation (ACGIH 1986, p. 361).

Mesityl oxide is an irritant of the eyes and mucous membranes in both animals and humans; at high concentrations, it also causes central nervous system depression. The oral LD_{50} in rats is 1120 mg/kg, the LC_{50} in the same species is 9 g/ms for 4 hours, and the dermal LD_{50} in rabbits is 5150 mg/kg (RTECS 1990). In contact with the eyes of rabbits, mesityl

oxide caused moderate to severe irritation; in contact with the skin of rabbits, this substance caused mild irritation (RTECS 1990). All guinea pigs exposed to a 2000-ppm concentration of mesityl oxide for up to 422 minutes died. The exposed animals exhibited eye and respiratory tract irritation, gradual loss of corneal and auditory reflexes, and coma before death (Specht, Miller, Valaer et al. 1940). Slight liver, kidney, and lung injury and irritation of the eyes and nose occurred in animals of two species exposed to a 500-ppm concentration for 8 hours a day for 10 days (Specht, Miller, Valaer et al. 1940). Experimental animals exposed to the vapor of mesityl oxide have shown signs of progressive central nervous system depression (Gosselin, Smith, and Hodge 1984, p. II-185). Guinea pigs exposed to mesityl oxide concentrations of 2300, 5000, or 10,000 ppm for as long as 8 hours showed dose-dependent central nervous system effects, as well as signs of respiratory irritation, reduced body temperature, reductions in heart rate and respiratory rate, and loss of reflexes (Clayton and Clayton 1982, p. 4753). Rabbits exposed to a 25-ppm concentration 4 hours/day for 189 days developed anemia and leukopenia (Clayton and Clayton 1982, p. 4753). Smyth, Seaton, and Fischer (1942/Ex. 1-378) reported liver and kidney damage among rats and guinea pigs continuously exposed to a 100-ppm concentration of mesityl oxide for 6 weeks; no adverse effects were reported in animals exposed to 50 ppm.

Silverman, Schulte, and First (1946/ Ex. 1-142) found that a majority of test subjects experienced eye irritation on exposure to a 25-ppm concentration of mesityl oxide for 15 minutes and nasal irritation on exposure to 50 ppm. Prolonged or repeated skin contact with this substance causes dermatitis (Proctor, Hughes, and Fischman 1988, p. 312). Exposure to mesityl oxide at high (not further specified) concentrations causes signs of central nervous system depression, such as headache, dizziness, tremors, incoordination, weakness, and decreases in heart and respiratory rate

(HSDB 1988).

After reviewing the health evidence for this substance, OSHA preliminarily finds that the proposed 15-ppm TWA and 25-ppm STEL limits are necessary to protect workers in construction, maritime, and agriculture against both the acute and chronic effects associated with exposure to this substance. These effects include possible liver and kidney damage as well as central nervous system depression and eye, mucous membrane, and skin irritation. The

Agency considers these exposurerelated effects material impairments of health and functional capacity. To reduce these significant occupational risks, OSHA is therefore proposing limits for mesityl oxide of 15 ppm as an 8-hour TWA and 25 ppm as a 15-minute STEL. Promulgation of these limits for workplaces in the construction, maritime, and agriculture sectors will make OSHA's PELs for this substance consistent across all OSHA-regulated

METHYL ACRYLATE CAS: 98-33-3; Chemical Formula: CH2=CHCOOCH3 H.S. No. 2105

OSHA's PEL for methyl acrylate in general industry, construction, and maritime is 10 ppm as an 8-hour TWA, with a skin notation; there is no PEL in agriculture. The ACGIH has a TLV*-TWA for methyl acrylate of 10 ppm, with a skin notation; there is no NIOSH REL for this substance. OSHA is proposing an 8-hour TWA PEL of 10 ppm, with a skin notation, for methyl acrylate in agriculture. This is the limit recently established for this substance

in general industry.

Methyl acrylate is a clear, colorless liquid with an acrid odor (HSDB 1986; ACGIH 1986, p. 369). It is used primarily to produce acrylic and modacrylic fibers. In the dental, medical, and pharmaceutical industries, it is used as a monomer, polymer, and copolymer (IARC 1979, p. 55; Proctor, Hughes, and Fischman 1988, p. 318). Methyl acrylate is also used in paints, coatings, adhesives, plastic panels, and textile finishes (Gosselin, Smith, and Hodge 1984, p. II-409). This substance also finds use as an aid in the timed release and disintegration of pesticides (Clayton and Clayton 1982, p. 2293). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Methyl acrylate causes irritation of the eyes, mucous membranes, respiratory tract, and skin; it has also been shown to cause dermal sensitization and systemic toxicity in both humans and laboratory animals. The oral LD50 in rats is 277 mg/kg, and the dermal LD50 in rabbits is 1243 mg/kg (RTECS 1991). By inhalation, methyl acrylate causes death in 50 percent of rats exposed to a concentration of 1350 ppm for 4 hours (RTECS 1991). In rabbits, dyspnea, cyanosis, convulsions, and death resulted from a single oral dose of 280 mg/kg (Treon et al. 1949). Rabbits exposed to a 237-ppm concentration of methyl acrylate for 7

hours/day for 11 days exhibited conjunctival and nasal irritation, lacrimation, and labored breathing (Treon et al. 1949). Methyl acrylate causes contact sensitivity in guinea pigs, and contact of this substance with the skin of rabbits causes marked irritation (Treon 1949; Parker and Turk 1983). Methyl acrylate caused moderate irritation when tested on rabbit eyes (RTECS 1991; Grant 1988, p. 1044). In contact with the eye, methyl acrylate causes severe burns of the cornea (HSDB 1986). In laboratory animals, repeated dermal application of small amounts of methyl acrylate caused systemic poisoning in the form of lung. liver, and kidney damage (Gosselin, Smith, and Hodge 1984, p. II-409).

In humans, the lowest concentration of methyl acrylate reported to have irritant effects is 75 ppm (Sandmeyer and Kirwin 1981). Rapid breathing. headache, nausea, lethargy, pulmonary edema, convulsions, and death may result from the inhalation of high (not further specified) concentrations of methyl acrylate (Gosselin, Smith, and Hodge 1984, p. II-409). A fatality resulted from the subcutaneous injection of a 1000 mg/kg dose of methyl acrylate (Clayton and Clayton 1982, p. 2294). An industry study involving 105 workers exposed to methyl acrylate showed positive sensitization reactions in 76.1 percent of the workers; 53.7 percent of these workers showed clinical evidence of having three allergies (dermatitis, eczema, and urticaria) (Khromov 1974). In contact with the skin, 20 parts methyl acrylate per hundred parts of olive oil causes irritation in one-third of individuals and allergic responses in approximately one out of 10 persons (Cavelier et al. 1981).

Based on this evidence in humans and animals, OSHA preliminarily concludes that agricultural workers exposed to this substance at the levels permitted by the absence of a permissible exposure limit are at significant risk of experiencing irritation of the eyes, skin, mucous membranes, and respiratory tract. The Agency believes that establishing a TWA PEL of 10 ppm, with a skin notation, is necessary to protect workers in agriculture from these significant risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

METHYL 2-CYANOACRYLATE CAS: 137-05-3; Chemical Formula: CH2 = C(C=N)COOCH3 H.S. No. 1248

OSHA has no limit for methyl 2cyanoacrylate in the construction.

agriculture, or maritime industries. The ACGIH has a TLV*-TWA of 2 ppm and a TLV*-STEL of 4 ppm for this substance; there is no NIOSH REL. The Agency is proposing a 2-ppm 8-hour TWA and a 4-ppm STEL for methyl 2cyanoacrylate in the construction. agriculture, and maritime industries OSHA recently established these PELs in general industry, and NIOSH (Ex. 8-47) concurred that these limits were appropriate for this substance.

Methyl 2-cyanoacrylate is a colorless, viscous liquid that is used to manufacture adhesives, super-glues, and polymers (ACGIH 1986, p. 383; Gosselin, Smith, and Hodge 1984, p. II-409).

Methyl 2-cyanoacrylate is an irritant of the eyes, nose, and upper respiratory tract. The oral LD50 in rats is 1.6 to 3.2 g/ kg, and the dermal LD50 in guinea pigs is greater than 10 ml/kg (ACGIH 1986, p. 383). The LC50 in rats is 101 ppm for 6 hours (ACGIH 1986, p. 383). The adverse effects reported in laboratory animals are slight irritation of the skin and corneal damage. Repeated exposures [6 hours/day for 5 days/week) to a concentration of 31.3 ppm for a total of 12 exposures caused only a slight decrease in the rate of weight gain in rats and no nasal or tracheal lesions or systemic toxicity (ACGIH 1986, p. 383). No changes were observed in rats similarly exposed to a concentration of 3.1 ppm (Eastman Kodak 1985, as cited in ACGIH 1986/Ex. 1-3, p. 383). Administered intratesticularly to monkeys at a dose of 100 mg/kg, methyl 2-cyanoacrylate caused reproductive effects (RTECS 1991).

In a simulated workbench exposure. McGee and co-workers reported nasal irritation in humans when the concentration of methyl 2-cyanoacrylate reached 3 ppm and eye irritation at a concentration of 5 ppm (McGee, Oglesby, Raleigh, and Fassett 1968/Ex. 1-424). In contact with the eyes, this substance causes corneal inflammation; however, recovery is usually complete (Grant 1986, p. 291). In contact with the skin of humans, it causes mild irritation

(HSDB 1991).

Based on this evidence in humans and animals, OSHA preliminarily concludes that employees in construction, maritime, and agriculture are at risk of experiencing nasal irritation on exposure to methyl 2-cyanoacrylate concentrations of 3 ppm or above and of eye irritation at concentrations of 5 ppm or above. The Agency believes that these adverse effects are material impairments of health and that the proposed PELs are necessary to substantially reduce these significant risks. Accordingly, OSHA is proposing a 2-ppm 8-hour TWA limit and a 4-ppm

STEL for methyl 2-cyanoacrylate in the construction, agriculture, and maritime industries. Promulgation of these limits will make the PELs for methyl 2cyanoacrylate consistent across all OSHA-regulated sectors. METHYL ISOBUTYL CARBINOL CAS: 108-11-2; Chemical Formula: CH3CHOHCH2CH(CH3)2

H.S. No. 1261

OSHA has an 8-hour TWA limit of 25 ppm, with a skin notation, for methyl isobutyl carbinol in the construction and maritime industries. The ACGIH has an 8-hour TLV®-TWA of 25 ppm, a TLV®-STEL of 40 ppm, and a skin notation for methyl isobutyl carbinol. NIOSH has no REL for this substance. OSHA is retaining the 8-hour TWA PEL of 25 ppm in construction and maritime, proposing to add a 15-minute STEL of 40 ppm for methyl isobutyl carbinol in these two sections, and additionally proposing both limits for workplaces in agriculture. NIOSH (Ex. 8-47) concurred that these limits, which were recently established for methyl isobutyl carbinol in general industry, are appropriate for this substance.

Methyl isobutyl carbinol is a colorless, stable liquid. It is used as a solvent for dyestuffs, oil, gums, resins, waxes, and cellulose esters. Methyl isobutyl carbinol is also used in flotation processes and brake fluids and as an intermediate in chemical synthesis (ACGIH 1986, p. 401; Clayton and

Clayton 1982, p. 4613).

In addition to sensory irritation, methyl isobutyl carbinol causes central nervous system depression in humans and experimental animals. The oral LD50 in rats is 2590 mg/kg, the lowest lethal concentration in the same species is 2000 ppm for 4 hours, and the dermal LD50 in rabbits is 3560 mg/kg (RTECS 1990). Anesthesia was observed in two of five mice given 1.0 ml/kg of methyl isobutyl carbinol orally; all exposed mice became anesthetized when the dose was increased to 1.5 or 2.0 ml/kg (McOmie and Anderson 1949). Gastrointestinal irritation and mesenteric congestion were also observed in these animals at autopsy (McOmie and Anderson 1949). Applied to the skin of rabbits, a dose of 10 mg methyl isobutyl carbinol produced mild irritation; instilled into rabbit eyes, methyl isobutyl carbinol caused severe irritation (RTECS 1990).

At a concentration of 50 ppm for 15 minutes, human volunteers experienced eye irritation (Silverman et al. 1946). At concentrations above 50 ppm, nose and upper respiratory tract irritation occurred (Silverman et al. 1946). It is expected that narcosis would also be

experienced by humans exposed to high concentrations of methyl isobutyl carbinol.

In view of the finding that exposure to a 50-ppm concentration of methyl isobutyl carbinol can result in eye irritation in humans in as little as 15 minutes, OSHA has preliminarily concluded that a limit on both full-shift and short-term exposure is necessary. The Agency considers the irritant and narcotic effects associated with exposure to this substance to be material impairments of health. To reduce these significant risks, OSHA is proposing a 25-ppm 8-hour TWA, a 15minute STEL of 40 ppm, and a skin notation for this substance in the construction, maritime, and agricultural industries. Promulgation of these limits will make the PELs for methyl isobutyl carbinol consistent across all OSHAregulated sectors.

METHYL ISOCYANATE CAS: 624-83-9; Chemical Formula: CH₃NCO H.S. No. 2106

OSHA's PEL for methyl isocyanate in general industry, construction, and maritime is 0.02 ppm as an 8-hour TWA, with a skin notation; there is no PEL in agriculture. The ACGIH TLV*-TWA for methyl isocyanate is 0.02 ppm as an 8hour TWA, with a skin notation; there is no NIOSH REL for this substance. OSHA is proposing to extend the 8-hour TWA PEL of 0.02 ppm, and the skin notation, to agriculture. Promulgation of this PEL will make OSHA's limit for this substance consistent across all regulated sectors.

Methyl isocyanate is the chemical responsible for the disaster in Bhopal, India, in 1984 that killed 2,000 people and affected as many as 100,000 individuals. This substance is used in the manufacture of carbaryl insecticides and in the production of polyurethane plastics and foams (ACCIH 1986, p. 403).

Methyl isocyanate is a severe irritant of the eyes, mucous membranes, and skin and a skin and pulmonary sensitizer in both humans and animals. The oral LD50 in rats is 69 mg/kg, and the LC50 in the same species is 6.1 ppm for 6 hours (RTECS 1990). The dermal LDso in rabbits is 213 mg/kg (RTECS 1990). Acutely poisoned animals exhibit signs of severe eye and pulmonary irritation before death (ACGIH 1986, p. 403). Application of this substance to the skin of rabbits, followed by occlusion, resulted in bleeding and marked edema of the skin (ACGIH 1986, p. 403). All 16 guinea pigs that were challenged with 0.01 ml of a 0.01 percent solution of methyl isocyanate developed skin

sensitization (ACGIH 1986, p. 403). On a 1 to 10 scale of increasing severity. methyl isocyanate caused corneal damage to rabbit eyes that was rated 10 (Smyth and Carpenter 1969). Rats exposed to a 0.21 ppm concentration of methyl isocyanate for 30 minutes on each of 6 days were followed for 90 days after exposure; although all of the rats survived, their lungs showed damage at autopsy (Sethi, Dayal, and Singh 1989). When administered to rats by inhalation or by intravenous or subcutaneous administration, methyl isocyanate caused a dose-related depression in cardiovascular activity (Kumar, Sachan, Pant, et al. 1989). After a single 2-hour exposure to methyl isocyanate at a concentration of 1, 3, or 10 ppm, male and female rats in the 10-ppm group had a 42 and 36 percent incidence, respectively, of fibrosis of the secondary bronchi (Bucher and Uraih 1989). In all dose groups, male rats (but not females or mice of either sex) showed slight increases in the incidence of pheochromocytomas of the adrenal medulla and adenomas of the pancreas (Bucher and Uraih 1989).

Human volunteers exposed to methyl isocyanate at a concentration of 0.04 ppm for 1 to 5 minutes reported experiencing no effects, but exposure to a 2-ppm concentration caused tearing, and increasing the concentration to 21 ppm caused "unbearable" irritation (Kimmerle and Eben 1964). In another experiment, however, a 10-minute exposure to a 0.05-ppm concentration caused eye irritation in all exposed volunteers (ACGIH 1986, p. 403). Some individuals exposed to methyl isocyanate develop pulmonary sensitization (Proctor, Hughes, and Fischman 1988, p. 337). Exposure causes the following signs and symptoms of severe respiratory irritation: difficult breathing, chest pain, coughing, and increased bronchial secretion (Rye 1973). The victims of the Bhopal disaster died of pulmonary edema, which was often accompanied by destruction of the alveolar walls (Marwick 1985). The victims also experienced severe visual impairment and showed clinical signs of damage to the liver and kidneys (Marwick 1985).

Based on this evidence in humans and animals, OSHA preliminarily concludes that agricultural workers exposed to methyl isocyanate at the concentrations permitted in the absence of a limit are at significant risk of experiencing severe eye and lung irritation as well as pulmonary sensitization. The Agency believes that establishing a PEL of 0.02 ppm as an 8-hour TWA will protect workers in agriculture from these

significant risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. METHYL MERCAPTAN CAS: 74-93-1; Chemical Formula: CH₃SH

H.S. No. 1263 OSHA has a ceiling limit of 0.5 ppm for methyl mercaptan in the construction and maritime industries. There is no PEL for agriculture. The ACGIH has a TLV®-TWA of 0.5 ppm for methyl mercaptan. NIOSH has a 15-minute ceiling limit of 0.5 ppm for this substance. OSHA is proposing an 8-hour TWA of 0.5 ppm for methyl mercaptan in the construction, maritime, and agriculture industries. This is the limit recently established for this substance in general industry

Methyl mercaptan is a flammable, water-soluble gas with a disagreeable odor like that of rotten cabbage. Methyl mercaptan is used in the production of pharmaceuticals, pesticides, fumigants, fungicides, jet fuel, dyes, and plastics. It is also used to give odor to natural gas and to synthesize methionine (ACGIH 1986, p. 405; Clayton and Clayton 1981,

p. 2066).

In addition to sensory irritation, methyl mercaptan causes narcosis and pulmonary edema in humans and experimental animals. In rats, the LC50 is 675 ppm for 4 hours (RTECS 1990). In one study, animals exposed to methyl mercaptan experienced restlessness, muscular weakness, paralysis, convulsions, respiratory depression, and cyanosis (Shults, Fountain, and Lynch 1970). Male rats exposed to concentrations of methyl mercaptan ranging from 1600 to 2200 ppm for an unspecified period lost their righting reflexes, but female rats exposed to 500 ppm for 30 to 35 minutes showed no adverse effects (Clayton and Clayton 1981, p. 2068). Rats exposed continuously for 90 days to a 50-ppm concentration of methyl mercaptan showed hematologic and lung effects, and mice exposed on the same regimen showed both hematologic and hepatic effects (Clayton and Clayton 1981, p.

A worker found comatose after emptying containers of methyl mercaptan developed elevated blood pressure, wheezing, tachycardia, rigidity of the extremities, and deep coma; death was caused by a pulmonary embolus that developed 28 days after exposure. Before death, this worker, who had a glucose-6-phosphate dehydrogenase deficiency, developed methemoglobinemia and severe hemolytic anemia (Proctor, Hughes, and Fischman 1988, p. 338). In a nonfatal

incident involving methyl mercaptan exposure, the exposed worker became cyanotic, experienced convulsions, and subsequently developed a lung abscess (Shults, Fountain, and Lynch 1970). A 1918 report by Pickler (Clayton and Clayton 1981, p. 2068) describes the accidental exposure (for several hours) of 28 students to a concentration of methyl mercaptan estimated to be 4 ppm. These individuals experienced headaches and nausea that lasted for 24 hours, and one student showed signs of liver involvement, demonstrated by the appearance of epithelial cells, protein, and red blood cells in the urine; these effects subsided in 6 weeks (Clayton and Clayton 1981, p. 2068). In another incident involving accidental overexposure to an unknown concentration of methyl mercaptan, the worker reported signs of mucosal and respiratory tract irritation and developed bronchopneumonia 20 hours later; this patient later recovered fully (Clayton and Clayton 1981, p. 2068). Long-term exposure to low concentrations (not further specified) of methyl mercaptan caused dermatitis in exposed individuals (Clayton and Clayton 1981, p. 2068)

Based on this evidence in humans and animals, OSHA preliminarily concludes that methyl mercaptan poses significant risks of mucous membrane and respiratory tract irritation, dermatitis, central nervous system effects, and possible liver damage to workers in the construction, maritime, and agriculture industries. The Agency believes that the proposed 8-hour TWA PEL of 0.5 ppm is necessary to substantially reduce the risk of these exposure-related effects, which constitute material impairments of health. Promulgation of this limit will also make OSHA's PEL for methyl mercaptan consistent across all OSHAregulated sectors.

METHYL METHACRYLATE CAS: 80-62-6; Chemical Formula: CH₂=C(CH₃)COOCH₃ H.S. No. 2107

OSHA's PEL for methyl methacrylate in general industry, construction, and maritime is 700 ppm as an 8-hour TWA: there is no PEL in agriculture. The ACGIH TLV*-TWA for this substance is 100 ppm as an 8-hour TWA; there is no NIOSH REL. OSHA is proposing an 8hour TWA of 100 ppm for methyl methacrylate in agriculture. This is the limit recently established for this substance in general industry.

Methyl methacrylate is a colorless liquid that is used captively in the production of acrylic polymers. This substance also finds use in the

manufacture of surface coating resins (latexes, lacquers, and enamels). Latex house paints, interior gloss and semigloss paints, and interior flat wall and ceiling paints account for the major portion of methyl methacrylate used in this country (IARC 1979, p. 189). This substance is also an ingredient in many consumer goods, including floor polishes, adhesives, binders, paper coatings, sealants, leather base coatings and finishes, and many other applications (IARC 1979, p. 189).

Methyl methacrylate is an eye, skin, and upper respiratory tract irritant, a central nervous system depressant and neurotoxin, and a skin sensitizer. In animals, it is also embryotoxic and produces developmental effects. The oral LD50 in rats is 7872 mg/kg; in mice, the LC₅₀ is 18,500 mg/m³ (4500 ppm) for 2 hours (RTECS 1990). Dogs exposed to lethal concentrations (11,000 ppm) of methyl methacrylate showed signs of central nervous system depression and a drop in blood pressure before dying of respiratory arrest; autopsy revealed damage to the liver and kidneys (Speakman et al. 1945). Male rats exposed over a 5-month period to a methyl methacrylate concentration of 116 ppm for 7 hours/day, 5 days/week showed, at autopsy, tracheal mucosa that were denuded of cilia (Tansy et al. 1980). Pregnant rats exposed on gestation days 6 through 15 to a 27,500ppm concentration of methyl methacrylate for less than 1 hour displayed signs of maternal toxicity, and their offspring had an increased incidence of fetal death, hematomas, and skeletal deformities (Nicholas et al. 1979). In another teratogenicity study, methyl methacrylate caused embryotoxic and developmental effects in the offspring of rats given intraperitoneal injections during pregnancy (RTECS 1990). A 2-year cancer bioassay conducted by the National Toxicology Program reported no evidence of carcinogenicity in male and female rats and mice exposed to methyl methacrylate concentrations ranging from 250 to 1000 ppm (NTP 1986).

Workers exposed to airborne concentrations of methyl methacrylate ranging from 170 to 250 ppm complained of irritation, and some reports place the human irritation level at 125 ppm (ACGIH 1986, p. 406; Seravotsnoe 1976; RTECS 1990). Dental technicians who regularly handle methyl methacrylate cement have developed paresthesias of the fingers, indicating axonal degeneration in those areas of the fingers in contact with the cement (Seppalainen and Rajaniemi 1984). In

one group of 200 workers exposed to the vapor at a concentration of 2 to 200 mg/m³ (0.5 to 50 ppm), 119 individuals reported headaches and several others complained of excessive fatigue, sleep disturbances, loss of memory, and irritability (IARC 1979, p. 194). There are reports of skin sensitization in humans 10 days after skin application, and several volunteers reacted when challenged with liquid methyl methacrylate (Lefaux 1968).

Based on this evidence in humans and animals, OSHA preliminarily concludes that agricultural workers exposed to this substance at the levels permitted by the absence of a limit are at significant risk of experiencing sensory irritation, axonal neuropathies, and skin sensitization. OSHA considers these effects material impairments of health. The Agency believes that establishing a PEL of 100 ppm as an 8-hour TWA will substantially reduce these risks for workers in agriculture. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. METHYL n-AMYL KETONE CAS: 110-43-0; Chemical Formula:

CH₃COC₅H₁₁ H.S. No. 1264

The OSHA limit for methyl n-amyl ketone in the construction and maritime industries is 100 ppm as an 8-hour TWA. There is no PEL for this substance in agriculture. The ACGIH has a TLV®-TWA of 50 ppm, and NIOSH has a REL for this substance of 100 ppm as a 10hour TWA. OSHA is retaining its current limit of 100 ppm as a TWA for methyl n-amyl ketone in the construction and maritime sectors and is proposing the same limit for agriculture. NIOSH (Ex. 150) agreed that a 100-ppm PEL for methyl n-amyl ketone was appropriate when the Agency recently, established this limit in general industry. Extending this PEL to agriculture will thus make OSHA's limit for this substance consistent across all OSHAregulated sectors.

Methyl n-amyl ketone, also called 2heptanone, is a water-white liquid with a fruity odor. It is used as a solvent for synthetic resin finishes and nitrocellulose lacquers, as a flavoring agent, and in perfumes (ACGIH 1986, p. 374; Hawley's 1987, p. 758).

In addition to sensory irritation, methyl n-amyl ketone causes narcosis in experimental animals. The oral LD₅₀s in rats and mice are 1670 mg/kg and 730 mg/kg, respectively (RTECS 1990). The lowest lethal concentration in rats is 4000 ppm for 4 hours (RTECS 1990). The dermal LD₅₀ in rabbits is 12,600 mg/kg (RTECS 1990). Exposing guinea pigs to

4800 ppm of methyl n-amyl ketone caused narcosis and death in 4 to 8 hours; exposure to a concentration of 2000 was strongly narcotic (Specht et al. 1940). In contact with the skin of rabbits, methyl n-amyl ketone caused mild irritation (RTECS 1990). Instilled into rabbit eyes, this substance caused injury rated 2 on an ascending severity scale of 1 to 10 (HSDB 1985). Johnson et al. (1978/Ex. 1-335) found no neurologic impairment in rats and monkeys exposed to 131 ppm or 1025 ppm methyl n-amyl ketone 6 hours/day, 5 days/ week for 9 months, and no gross or histopathologic changes were found in these animals at autopsy (Johnson, Setzer, Lewis, and Hornung 1978/Ex. 1-335).

There are no case reports of industrial poisonings in exposed workers, and the concentration at which irritation or narcosis would begin in humans is not known. Methyl n-amyl ketone has been tested in volunteers for its potential to cause skin sensitization, and the results of these tests have been negative (Clayton and Clayton 1981, p. 4758).

Based on this evidence, OSHA is retaining its 8-hour TWA PEL of 100 ppm for methyl n-amyl ketone in the construction and maritime industries and is proposing to extend this limit to workplaces in agriculture. The Agency preliminarily finds that, based on effects seen in animals, exposure to this substance is likely to be associated with both irritant and narcotic effects and that these effects constitute material health impairments. To reduce these significant occupational risks, OSHA is therefore proposing an 8-hour TWA PEL of 100 ppm in agriculture for methyl namyl ketone. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

alpha-METHYL STYRENE CAS: 98-83-9; Chemical Formula: C₆H₅C(CH₅)=CH₂ H.S. No. 1267

OSHA has a ceiling limit of 100 ppm for alpha-methyl styrene in the construction and maritime industries. There is no limit in agriculture. The ACGIH has a 50 ppm TLV*-TWA and a 100 ppm TLV*-STEL for alpha-methyl styrene. NIOSH has no REL for this substance. The Agency is proposing a 50-ppm 8-hour TWA and a 10-ppm 15-minute STEL for alpha-methyl styrene in the agriculture, construction, and maritime industries. NIOSH (Ex. 8-47) concurred with these limits when the Agency recently established them for alpha-methyl styrene in general industry.

alpha-Methyl styrene is a combustible, colorless liquid that has a sharp, aromatic odor and is used as a polymerization monomer. This substance also finds use as a chemical intermediate (Clayton and Clayton 1981, p. 3324).

In addition to sensory irritation, alpha-methyl styrene causes central nervous system depression in humans and experimental animals. The oral LD50 in rats is 4900 mg/kg, and the lowest lethal concentration in the same species is 3000 ppm for an unspecified period of time (RTECS 1990). Applied to the eyes of rabbits, a dose of 91 mg caused a mild degree of irritation; in contact with the skin, alpha-methyl styrene caused moderate irritation (RTECS 1990). Twenty applications of this substance to rabbit skin, however, caused inflammation, hyperemia, edema, and hyperkeratosis (Clayton and Clayton 1981, p. 3324). Guinea pigs and rats exposed to 3000 ppm 7 hours/day for 3 to 4 days died. At autopsy, slight liver and kidney changes were observed in guinea pigs after exposure to 800 ppm for 27 days (Wolf et al. 1956/Ex. 1-404). Rats, guinea pigs, rabbits, mice, and monkeys exposed 7 hours/day, 5 days/ week for 6 months to a 200-ppm concentration of alpha-methyl styrene showed no adverse effects either on gross or microscopic examination (Wolf, Rowe, McCollister et al. 1956/Ex. 1-404). A 1981 NIOSH teratogenicity study in pregnant rats injected intraperitoneally with alpha-methyl styrene on days 1 through 15 of gestation showed that, at a dose of 250 mg/kg, alpha-methyl styrene caused a significantly increased number of resorptions (Hardin, Bond, Sikov, Andres, Beliles, and Niemier 1981; Scand. J. Work Environ. Health 7(4):66-

In humans, a 2-minute exposure to a 200-ppm concentration of alpha-methyl styrene caused eye irritation and complaints about this substance's unpleasant odor (Wolf et al. 1956/Ex. 1-404). A Russian study in workers exposed for 4 to 5 years to alpha-methyl styrene at concentrations of 3 to 7 mg/ m3 (0.6 to 1.5 ppm) reports that these workers showed signs of occupational poisoning, including asthenia, vasovegatative disorders, reduced arterial pressure, and hematopoietic changes (temporary leukemia, thrombocytopenia, and reticulocytopenia) (Kapkaev and Suhanova 1986). Another Russian study reports a high incidence of sensitization dermatitis in workers in a synthetic rubber plant who were dermally exposed to alpha-methyl styrene and

other substances during rubber manufacture (Mirzoyan 1972).

To ensure that workers in construction, maritime, and agriculture are protected against the irritant, sensitization, and narcotic effects of exposure to this substance, OSHA is proposing a 50-ppm 8-hour TWA limit and a 100-ppm 15-minute STEL for alpha-methyl styrene in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that these combined limits are necessary to substantially reduce the risk that workers in these sectors will experience these exposure-related effects, which constitute material impairments of health. Promulgation of these limits will also make OSHA's PELs for this substance consistent across all OSHA-regulated industries. o-METHYLCYCLOHEXANONE CAS: 583-60-8; Chemical Formula:

CH₃C₆H₉CO H.S. No. 1270

OSHA's limit for omethylcyclohexanone in construction and maritime is 100 ppm as an 8-hour TWA, with a skin notation. There is no limit in agriculture. The ACGIH has a 50-ppm 8-hour TLV®-TWA, a 75-ppm 15minute TLV®-STEL, and a skin notation for o-methylcyclohexanone. NIOSH has no REL for this substance. The Agency is proposing PELs of 50 ppm as an 8-hour TWA and 75 ppm as a 15-minute STEL, and a skin notation, for omethylcyclohexanone in construction, maritime, and agriculture. NIOSH (Ex. 8-47) concurred that these limits were appropriate for o-methylcyclohexanone when the Agency recently established them in general industry.

ortho-Methylcyclohexanone is a somewhat viscous liquid with an acetone-like odor. It is a solvent that is used in the manufacture of lacquers, varnishes, and plastics. ortho-Methylcyclohexanone is also used in the leather industry and as a rust remover (ACGIH 1986, p. 386). The commercial product contains a mixture of isomers; however, toxicity data describe the effects of the ortho isomer only.

In addition to sensory irritation, omethylcyclohexanone causes narcosis in experimental animals and may also do so in humans. The oral LD₅₀ in rats is 2140 mg/kg, and the dermal LD₅₀ in rabbits is 1635 mg/kg (RTECS 1991). The LC₅₀ in rats is 2890 ppm for 4 hours (Smyth et al. AIHAJ 30:470, 1969). In contact with the eyes of rabbits, omethylcyclohexanone caused injury graded 5 on an ascending severity scale of 1 to 10 (Grant 1986, p. 1045). At an exposure concentration of 2500 ppm, rabbits and cats experienced

drowsiness and difficult and irregular respiration and had a staggering gait (Lehman and Flury 1943a/Ex. 1-962). After 15 minutes of exposure to 3500 ppm, several species of animals lost coordination; after 30 minutes, the animals became prostrate. Rabbits exposed to 1822 ppm for 6 hours/day for 3 weeks showed signs of conjunctival irritation, became lethargic, and salivated excessively (Lehman and Flury 1943a/Ex. 1-962). Repeated application of large doses of omethylcyclohexanone to the skin of rabbits produced irritation, tremor, narcosis, and death; the minimal lethal dose was reported to be between 4.9 and 7.2 g/kg (Treon, Crutchfield, and Kitzmiller 1943. J. Ind. Hyg. Toxicol. 25:199-214).

There are no reports of chronic or systemic effects in humans exposed to this substance; however, it is expected that severe exposure to omethylcyclohexanone would produce the same irritant and narcotic effects in humans as in experimental animals (Proctor, Hughes, and Fischman 1988, p. 328). The American Conference of Governmental Industrial Hygienists (ACGIH) reports that exposure to a 100-ppm concentration will not cause narcotic effects but may cause eye and respiratory tract irritation (ACGIH 1986, p. 386).

Based on this evidence, OSHA preliminarily concludes that workers in construction, maritime, and agriculture who are exposed to omethylcyclohexanone are at significant risk of these exposure-related effects. The Agency considers the irritation potentially caused by exposure to this substance a material impairment of health and believes it necessary to establish PELs for omethylcyclohexanone of 50 ppm as an 8hour TWA and 75 ppm as a 15-minute STEL. These limits, and the skin notation, will substantially reduce this significant risk in construction, maritime, and agricultural workplaces. Promulgation of these PELs for omethylcyclohexanone will also make OSHA's limits for this substance consistent across all OSHA-regulated sectors.

OSMIUM TETROXIDE CAS: 20816-12-0; Chemical Formula: OsO₄ H.S. No. 1298

In construction and maritime operations, OSHA has an 8-hour TWA limit of 0.002 mg/m³ for osmium tetroxide. The ACGIH has a TLV*-TWA of 0.002 mg/m³ and a TLV*-STEL of 0.006 mg/m³; NIOSH has no REL for this

substance. OSHA is proposing to add a 15-minute STEL of 0.006 mg/m³ to the 8-hour TWA PEL of 0.002 mg/m³ for osmium tetroxide in the construction and maritime industries and to extend these limits to agriculture. NIOSH (Ex. 8-47) concurred that these limits are appropriate for this substance when the Agency recently established them in general industry.

Osmium tetroxide is a noncombustible, colorless to pale yellow solid with a disagreeable, chlorine-like odor. Osmium tetroxide is used as a fat stain in pathological laboratories. It is also used as an oxidizing agent for converting olefins to glycols, in photography, and as a catalyst in organic synthesis. Osmium tetroxide was formerly used in fingerprinting (ACGIH 1986, p. 450; Merck 1983, p. 989; AIHA 1968).

Osmium tetroxide causes severe eye, nose, and respiratory tract irritation in humans and experimental animals. The oral LD50s in rats and mice are 14 mg/kg and 162 mg/kg, respectively (RTECS 1990). The lowest lethal concentration in rats inhaling osmium tetroxide for 4 hours is 40 ppm (approximately 400 mg/ m3) (RTECS 1990). In contact with the eyes of rabbits, a 1 percent solution of osmium tetroxide caused severe corneal damage and permanent opacity (Grant 1986, p. 682). Exposure for 30 minutes to osmium tetroxide at a concentration of 130 mg/m3 caused irritation of the mucous membranes, labored breathing, and death in rabbits; at autopsy, pulmonary edema was evident (Brunot 1933/Ex. 1-776). Toxic bone marrow effects have been reported in guinea pigs exposed 8 hours/day for 60 days to an unspecified concentration of osmium tetroxide; these animals developed normochromic anemia, as evidenced by a decrease in the number of erythrocytes, leukocytes, and reticulocytes as well as a decrease in hemoglobin levels (Hamilton and Hardy 1974a/Ex. 1-957; HSDB 1989).

Industrial experience indicates that osmium tetroxide fume concentrations in a precious metal refining plant ranged from 0.1 to 0.6 mg/m3; intermittent exposure to these concentrations produced symptoms (sometimes delayed) of lacrimation, visual disturbance, frontal headache, conjunctivitis, and cough in exposed workers (McLaughlin, Milton, and Perry 1946/Ex. 1-749). Complaints of persistent and severe nose and throat irritation were also reported (Hamilton and Hardy 1974a/Ex. 1-957). One investigator (Brunot 1933/Ex. 1-776) developed lacrimation and corneal edema (manifested as haloes around

lights) after a brief exposure to osmium tetroxide at an unspecified concentration. Fairhall (1949d, as cited in ACGIH 1986/Ex. 1-3, p. 450) reported a human fatality resulting from inhalation exposure to osmium tetroxide (the concentration and duration of the exposure are not known). A laboratory worker heating osmium in the laboratory produced sufficient osmium tetroxide to cause blepharospasm, ocular pain, photophobia, and redness of the eyes (Grant 1986, p. 682). In contact with the skin, osmium compounds (including osmium tetroxide) cause eczema and dermatitis (AIHA 1968).

Based on this evidence in humans and animals, OSHA preliminarily concludes that exposure to osmium tetroxide, even for short periods, poses a significant risk of ocular and respiratory effects to exposed workers. The Agency considers these effects material impairments of health and preliminarily finds that the proposed limits are necessary to substantially reduce these significant risks. Accordingly, OSHA is proposing an 8-hour TWA PEL of 0.002 mg/m3 and a 15-minute STEL of 0.006 mg/m3 for osmium tetroxide in the construction, maritime, and agriculture sectors. Promulgation of these limits will make OSHA's PELs for this substance consistent across all OSHA-regulated sectors.

PARAFFIN WAX FUME CAS: 8002–74–2; Chemical Formula: C_nH₂n+₂ H.S. No. 1302

OSHA has no limit for paraffin wax fume in the construction, maritime, or agriculture industries. The ACGIH has a TLV*-TWA of 2 mg/m³; NIOSH has no REL for this substance. OSHA is proposing an 8-hour TWA limit of 2 mg/m³ for paraffin wax fume in construction, maritime, and agriculture. NIOSH (Ex. 8-47) concurred that this limit is appropriate for paraffin wax fume when the Agency recently established it in general industry.

Paraffin is a white or slightly yellow, odorless solid that is derived from petroleum. Paraffin is used for making candles, as a sealant or coating for paper and food products, for extracting perfumes from flowers, and as a chewing gum base. It has also been used in crayons, in stoppers for acid bottles, in cosmetics, in photography, as a lubricant, in the packaging of tobacco products, and as an anti-frothing agent in sugar refining (ACGIH 1986, p. 455; Hawley's 1987, p. 873).

In addition to mild eye, nose, and throat irritation (Genium MSDS 1990, No. 712), exposure to paraffin wax fume can cause nausea in humans. Instilled into rabbit eyes, 100 mg of paraffin caused mild irritation; applied to the skin of rabbits, this substance caused a mild degree of irritation (RTECS 1989). Although paraffin is relatively nontoxic in its solid state, the fume generated when it is in the molten state causes discomfort and nausea (Queries and Minor Notes, JAMA 1938/Ex. 1-308). In the most recent report of industrial exposure effects, paraffin fume is reported to cause no discomfort in most workers when the concentration is maintained at or below 2 mg/m3, although one instance of mild discomfort was reported at concentrations between 0.6 and 1 mg/m3 (Massachusetts Division of Occupational Hygiene 1970, as cited in ACGIH 1986/Ex. 1-3, p. 455). Chronic exposure of the skin to paraffin wax has caused dermatitis (Genium MSDS 1990, No. 712). There are reports that workers exposed to this substance for 10 years or longer have a higher than normal risk of developing scrotal cancer (Genium MSDS 1990, No. 712).

OSHA preliminarily finds that the adverse effects associated with excessive exposure to paraffin wax fume—sensory irritation and nausea—constitute material impairments of health. OSHA believes that the proposed PEL of 2 mg/m³ will substantially reduce these significant risks for workers in construction, maritime, and agriculture. In addition, promulgation of this limit will make the PEL for paraffin wax fume consistent across all OSHA-regulated sectors.

PHENYL ETHER
CAS: 101-84-8; Chemical Formula:
(C₆H₅)₂O
H.S. No. 1314

OSHA's permissible exposure limit for phenyl ether in general industry, construction, and maritime is an 8-hour TWA limit of 1 ppm. There is no PEL in agriculture. The ACGIH recommends a TLV*-TWA of 1 ppm and a TLV*-STEL of 2 ppm for phenyl ether. NIOSH has no REL. OSHA is proposing an 8-hour TWA PEL of 1 ppm for phenyl ether in agriculture. This is the limit recently established for this substance in general industry.

Phenyl ether is either a colorless liquid or a solid, depending on temperature; its vapor has a characteristically disagreeable odor. This substance finds use as a chemical intermediate, a heat-transfer medium, and an ingredient in perfumes and soaps (Hawley's 1987, p. 429). It is also used in the manufacture of high-temperature lubricants and surfactants (HSDB 1990).

Phenyl ether is an irritant of the eyes and skin (RTECS 1990; HSDB 1990). The

oral LD50 in rats is 3370 mg/kg (RTECS 1990); single oral doses of between 1 and 2 g/kg administered to experimental animals of various species have caused liver, spleen, kidney, thyroid, or gastrointestinal injury in those surviving the exposure (Vogel, Snyder, and Schulman 1964/Ex. 1-681). Repeated inhalation studies in rats, rabbits, and dogs have shown that a total of 20 exposures to a 4.9-ppm concentration of phenyl ether for 5 days/week, 7 hours/ day produced no adverse effects. Eye and nasal irritation were observed in rats and rabbits exposed to a 10-ppm concentration (Hefner, Leong, Kociba, and Gehring 1975/Ex. 1-329). Skin and eye irritation have been reported to result only from prolonged or repeated contact with the undiluted liquid.

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 1 ppm for the agriculture sector. The Agency preliminarily concludes that this limit will protect workers in agriculture from the odor and irritant effects associated with exposure to phenyl ether. OSHA believes that these effects are material impairments of health within the meaning of the Act. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. PHENYL ETHER-BIPHENYL MIXTURE CAS: 8004–13–5; Chemical Formulas:

(C₆H₅)₂O and C₆H₅C₆H₅ H.S. No. 2127

In general industry, construction, and maritime, OSHA's permissible exposure limit for phenyl ether-biphenyl mixture is 1 ppm as an 8-hour TWA. There is no limit for this substance in agriculture. The ACGIH has no current TLV* for this substance; there is no NIOSH REL. OSHA is proposing to establish a PEL in agriculture of 1 ppm as an 8-hour TWA for phenyl ether-biphenyl mixture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Phenyl ether-biphenyl mixture, also called Dowtherm A, is a straw-colored liquid that has a disagreeable aromatic odor and that darkens on use. This substance is used as a heat transfer agent, as a dye carrier for printing and textiles, and in the production of acetyl chloride and polyester fibers (NIOSH/OSHA Occupational Health Guideline 1981, p. 3).

Phenyl ether-biphenyl mixture causes irritation of the eyes, mucous membranes, and skin, and liver and kidney damage in humans and animals. The oral LD₅₀s in rats, mice, rabbits, and guinea pigs are 2460 mg/kg, 3210 mg/kg, 4200 mg/kg, and 3000 mg/kg, respectively (RTECS 1991). Rabbits

exhibited mild eye and skin irritation when 500 mg was applied to their eyes and skin, respectively, for 24 hours (RTECS 1991). Rabbits developed the following signs of mild skin irritation when undiluted Dowtherm A was applied daily to their ears: Hyperemia, edema, exfoliation, hair loss, and enlargement of the hair follicles (Hake and Rowe 1963, in Clayton and Clayton 1981, p. 2544). Small groups of rats given repeated doses of Dowtherm A by stomach tube (doses of 0.5 to 1.0 g/kg) 5 days/week for a total of 132 doses exhibited slight growth retardation and increased liver and kidney weights (rats in the 0.5 g/kg dose group); those given 1.0 g/kg had moderate growth depression and, at autopsy, showed histopathological changes in the kidneys, liver, and spleen (Hake and Rowe 1963, in Clayton and Clayton 1981, p. 2544). At autopsy, rats fed phenyl ether-biphenyl mixture at doses of 0.25 and 0.5 g/kg/day showed signs of moderate liver and kidney degeneration after 2 months of exposure (Hake and Rowe 1963, in Clayton and Clayton 1981, p. 2544). When subjected to 37 8-hour exposures to a 14-ppm concentration of this substance, rats, guinea pigs, and a monkey showed signs of emaciation, starvation, and a slight increase in liver weight; no significant histopathological changes were observed at autopsy (Hake and Rowe 1963, in Clayton and Clayton 1981, p. 2544). Rats, guinea pigs, rabbits, and monkeys exposed to the vapors of this substance at a concentration of 7 to 10 ppm for 7 hours/ day, 5 days/week for 6 months showed no adverse effects (HSDB 1991).

The lowest toxic concentration of phenyl ether-biphenyl mixture reported in humans is 3 ppm; at this concentration, irritation of the eyes, nose, and pulmonary tract were observed (RTECS 1991). Exposure to vapor concentrations of 7 to 10 ppm causes extreme nausea and is painful to the eyes and upper respiratory tract (Proctor and Hughes 1978, p. 412). In one case, a man was sprayed in the eyes with this substance; although there was no immediate discomfort, he felt stinging and burning of the eyes and the surrounding skin within 5 minutes (Grant 1986, p. 373). In four other cases, corneal burns resulted from exposure to diphenyl oxide; recovery was complete within 48 hours (Grant 1986, p. 373). Severe degenerative lesions of the liver and kidneys can result from accidental ingestion (Parmeggiani 1983, p. 643).

Based on this evidence in humans and animals, OSHA preliminarily concludes that exposure to phenyl ether-biphenyl mixture causes eye, mucous membrane, and skin irritation. The Agency believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these exposure-related effects and that the proposed PEL of 1 ppm as an 8-hour TWA will substantially reduce these risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

PHOSGENE
CAS: 75–44–5; Chemical Formula:
Cl₂C=O
H.S. No. 2129

In general industry, construction, and maritime, OSHA has an 8-hour TWA limit of 0.1 ppm for phosgene. There is no PEL for this substance in agriculture, The ACGIH TLV*-TWA for phosgene is 0.1 ppm (0.40 mg/m³) as an 8-hour TWA. The NIOSH REL for phosgene is 0.1 ppm (0.4 mg/m³) as a 10-hour TWA, with a 15-minute ceiling of 0.2 ppm (0.8 mg/m³). OSHA is proposing an 8-hour TWA PEL of 0.1 ppm for phosgene in agriculture. This is the limit recently established for this substance in general industry.

Phosgene is a poisonous, colorless, nonflammable gas or volatile liquid with a sweet, pungent, or musty odor (AIHA 1990, p. 1). Phosgene is used as an intermediate in the production of polyurethane, isocyanates, polycarbonates, pesticides, herbicides, pharmaceuticals, and dyes and as a chlorinating agent for the separation of uranium ores. This substance was used as a war gas in World War I. Phosgene gas is formed during arc or gas welding in the presence of chlorinated hydrocarbons, such as in locations with degreasing operations, and during the welding of aluminum (Grayson 1985, pp. 868-869; Hawley's 1987, p. 908; Braker and Mossman 1980, p. 596; AIHA 1990, p. 2). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Phosgene is a severe respiratory irritant; exposure to high concentrations causes pulmonary edema, and long-term exposure to low concentrations causes chronic lung disease. The LC50 in monkeys is 600 mg/m3 (150 ppm) for 1 minute, and the LCso in rats is 1400 mg/ m3 (350 ppm) for 30 minutes (RTECS 1991). Exposure of experimental animals to phosgene has caused extreme congestion, pulmonary edema, lobular and pseudolobular pneumonia, atelectasis, emphysema, and chronic pneumonitis (Chemical Manufacturer's Phosgene Panel 1988). Rats exposed to a 0.5-ppm concentration for 120 minutes developed chronic pneumonitis, with

thickening of the respiratory bronchioles and alveolar damage (Rinehart 1964; Cross 1965). Forty-one percent of all goats, cats, rabbits, guinea pigs, rats, and mice exposed to a 0.8-mg/m³ (0.2-ppm) concentration of phosgene for 5 hours/day for 5 consecutive days developed pulmonary edema and 4 percent of these animals developed extensive lung lesions (Cameron 1942). Cats exposed to high phosgene concentrations (not further specified) developed corneal opacification (Laquer 1921).

The acute hazard posed by exposure of humans to phosgene is pulmonary edema; the edema may not develop for 1to 24 hours after exposure (Diller 1985). Based on observations made when this substance was used in warfare, the estimated LCso in humans is 3200 mg/m3 (800 ppm) for 1 minute or 400 ppm for 2 minutes (Chemical Warfare Service 1944; Chasis 1944). In humans, the irritation caused by phosgene does not give sufficient warning of hazardous concentrations (Stokinger 1957). Exposure of humans to a 3-ppm concentration can cause immediate irritation of the throat, exposure to 4 ppm causes immediate irritation of the eyes, and exposure to 4.8 ppm causes coughing; brief exposure to 50 ppm can be rapidly fatal (Cucinell 1974). Liquid phosgene splashed into the eyes caused total opacification and perforation of both corneas in one individual (D'Osvaldo 1928). In contact with the skin, liquid phosgene causes skin burns (AIHA 1978). A group of 326 workers exposed to phosgene concentrations ranging from nondetectable to greater than 0.13 ppm showed no signs of chronic lung disease (NIOSH 1976). Six workers exposed chronically to low concentrations of phosgene developed chronic lung disease (Galdston, Luetscher, and Longcope et al. 1947).

The evidence described above shows that phosgene exposure causes severe irritation of the eyes and nose and damage to the lungs; exposure to high concentrations may cause pulmonary edema and death. Accordingly, OSHA preliminarily concludes that, in the absence of a limit, workers in agriculture are potentially at significant risk of experiencing these exposurerelated effects. The Agency believes that the proposed limit of 0.1 ppm for phosgene in agriculture will substantially reduce these risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. PHOSPHORIC ACID

CAS: 7664-38-2; Chemical Formula:

H₃PO₄

H.S. No. 1322

OSHA has a limit for phosphoric acid in the construction and maritime sectors of 1 mg/m³ as an 8-hour TWA. The ACGIH has a TLV*-TWA limit of 1 mg/m³ and a TLV*-STEL of 3 mg/m³ for phosphoric acid; NIOSH has no REL. The Agency is retaining an 8-hour TWA of 1 mg/m³ in construction and maritime, proposing a 15-minute STEL of 3-mg/m³ in these two sectors, and proposing both limits in agriculture. NIOSH (Ex. 8-47) concurred that these limits are appropriate for phosphoric acid when the Agency recently established them in general industry.

Phosphoric acid is a colorless, odorless solid at temperatures below 21°C but becomes a viscous, clear liquid at higher temperatures. It is used in fertilizers, pharmaceuticals, animal feed, detergents, foods, and beverages and in water treatment, pickling and rustproofing metals, sugar refining, and electropolishing. Phosphoric acid is also used as a catalyst in ethanol manufacture, as a binder for ceramics, and as a laboratory reagent (ACGIH 1986, p. 463; Hawley's 1987, p. 910).

Exposure to phosphoric acid causes sensory irritation; contact of the tissues with phosphoric acid also causes corrosive burns. The oral LD₅₀ in rats is 1530 mg/kg, and the dermal LD₅₀ in rabbits is 2740 mg/kg (RTECS 1990). In contact with the skin of rabbits for 24 hours, phosphoric acid caused severe skin irritation; instilled into the eyes of rabbits, this substance caused severe eye irritation (RTECS 1990).

In humans, phosphoric acid mist causes mild irritation of eyes, throat, and skin, and the dust is reported to be especially irritating to the skin when moisture is present. The AIHA Hygienic Guide for phosphoric acid reports that this substance is less hazardous than either nitric or sulfuric acid (AIHA 1957/ Ex. 1-709). The lowest lethal dose for humans (route not specified) is estimated to be 220 mg/kg (RTECS 1990). At concentrations ranging from 0.8 to 5.4 mg/m3, fumes of phosphorus pentoxide (the anhydride of phosphorus acid) caused no discomfort, but exposure to concentrations ranging from 3.6 to 11.3 mg/m3 caused coughing in unacclimated workers (Rushing 1957, in ACGIH 1986, p. 483). A dilute solution buffered to a pH of 2.5 caused stinging but no permanent eye injury when dropped into the human eye. A 75percent solution of this substance, however, caused severe burns when placed on the skin (AIHA Hygienic Guide Series 1957).

To protect workers in construction, maritime, and agriculture from the risk

of eye, skin, and respiratory tract irritation associated with exposure to this substance, OSHA is retaining the TWA limit of 1 mg/m3 in construction and maritime, proposing a STEL of 3 mg/m³ in these sectors, and proposing both limits in agriculture. The Agency preliminarily concludes that both 8-hour TWA and STEL limits are necessary to substantially reduce the risk that workers in these sectors will experience these material health impairments. In addition, promulgation of these limits will make OSHA's PELs for phosphoric acid consistent across all OSHAregulated sectors.

PHOSPHORUS PENTACHLORIDE CAS: 10026-13-8; Chemical Formula: PCl₅

H.S. No. 2131

OSHA's PEL for phosphorus pentachloride in general industry, construction, and maritime is 1 mg/m³ as an 8-hour TWA; there is no PEL in agriculture. The ACGIH has a TLV*-TWA of 0.1 ppm (1 mg/m³) for phosphorus pentachloride; there is no NIOSH REL. OSHA is proposing an 8-hour TWA PEL of 1 mg/m³ for phosphorus pentachloride in agriculture. This is the limit recently established for this substance in general industry.

Phosphorus pentachloride is a white to pale-yellow crystalline solid that fumes in moist air. It has a pungent, unpleasant odor (ACGIH 1986, p. 485; Proctor, Hughes, and Fischman 1988, p. 413). Phosphorus pentachloride is used in the manufacture of agricultural chemicals, plasticizers, chlorinated compounds, gasoline additives, surfactants, and pharmaceuticals. It is also used as a dehydrating agent and in the manufacture of acetylcellulose (Proctor, Hughes, and Fischman 1988, p. 413; Sittig 1985, p. 722). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

In contact with moisture or moist tissues, phosphorus pentachloride decomposes to phosphorus oxychloride, phosphoric acid, and hydrochloric acid (Clayton and Clayton 1982, p. 2126). Phosphorus pentachloride is a severe irritant of the eyes, mucous membranes, and upper respiratory tract. The oral LD₅₀ in rats is 660 mg/kg; the LC₅₀ for the same species is 205 mg/m³ for 4 hours (RTECS 1990). A concentration of 120 ppm phosphorus pentachloride was fatal to mice in 10 minutes (Proctor, Hughes, and Fischman 1988, p. 413; ACGIH 1986, p. 485).

In humans, exposure to phosphorus pentachloride (at an unspecified concentration) has caused irritation of the eyes and respiratory passages and the development of bronchitis (von Oettingen 1952). Workers exposed to high concentrations of this substance may experience erosion of dental enamel, and chronic exposure may lead to chronic bronchitis (Rom 1983, p. 498). Severe overexposure to phosphorus pentachloride vapor may cause delayedonset pulmonary edema. Repeated skin contact with this material may cause dermatitis (Proctor, Hughes, and Fischman 1988, p. 413).

Based on this evidence in humans and animals, OSHA preliminarily concludes that agricultural workers exposed to this substance at the levels permitted by the absence of a limit are at significant risk of experiencing eye, mucous membrane, and upper respiratory tract irritation and may also be at risk of developing chronic bronchitis. The Agency believes that establishing a PEL of 1 mg/m3 as an 8-hour TWA will protect workers in agriculture from these significant risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

PHOSPHORUS TRICHLORIDE CAS: 7719–12–2; Chemical Formula: PCl₃ H.S. No. 1325

In the construction and maritime industries, OSHA's limit for phosphorus trichloride is 0.5 ppm as an 8-hour TWA. The ACGIH has a TLV*-TWA of 0.2 ppm and a TLV*-STEL of 0.5 ppm. NIOSH has no REL for phosphorus trichloride but concurs [Ex. 8-47] that the proposed limits are appropriate. OSHA is proposing an 8-hour TWA PEL of 0.2 ppm and a 15-minute STEL of 0.5 ppm for workplaces in construction, maritime, and agriculture.

Phosphorus trichloride is a noncombustible, colorless, fuming liquid. Phosphorus trichloride is used as an intermediate in the preparation of pesticides, surfactants, gasoline additives, plasticizers, and dyestuffs. It is also used as a chlorinating agent and catalyst and as a ingredient of textile finishing agents (ACGIH 1986, p. 486).

In addition to severe sensory irritation, phosphorus trichloride causes corrosive burns in contact with the eyes or skin. The oral LD₅₀ in rats is 550 mg/kg, and the lowest lethal concentration in the same species is 104 ppm for 4 hours (RTECS 1990). Acutely poisoned animals showed nephrosis at autopsy (Weeks et al. 1984). Cats and guinea pigs showed signs of mild systemic poisoning after exposure to 0.7 ppm for 6 hours (Butjagin 1904, as cited in ACGIH 1986/

Ex. 1-3, p. 486). At a concentration of 2 to 4 ppm, cats developed breathing difficulty and conjunctivitis after 6 hours; when the concentration was increased to between 23 and 90 ppm, the corneas of these animals became cloudy (Grant 1986, p. 736). The primary occupational hazards associated with exposure to phosphorus trichloride are respiratory irritation and poisoning involving cough, bronchitis, pneumonia, and conjunctivitis (Henderson and Haggard 1943e/Ex. 1-1086; International Labour Office 1934b, as cited in ACGIH 1986/Ex. 1-3, p. 486; Sassi 1954/Ex. 1-931). The onset of pulmonary edema, which follows severe overexposures, may be delayed for several hours (Clayton and Clayton 1981, p. 2128). Long-term exposure leads to chronic cough and wheezing, although these effects are nonprogressive and are not associated with fibrotic lung disease (Proctor, Hughes, and Fischman 1988, p.

Because of the acutely irritating effects of this substance, OSHA preliminarily concludes that both a TWA and a STEL are necessary to substantially reduce the significant risk of respiratory and eye irritation potentially posed to workers exposed to phosphorus trichloride in construction, maritime, and agriculture. The Agency considers these adverse effects to be material impairments of health. Therefore, OSHA is proposing to revise its limit for phosphorus trichloride to 0.2 ppm as an 8-hour TWA and to add a 0.5 ppm 15-minute STEL for this substance in the construction, maritime, and agriculture industries. Promulgation of these limits will make OSHA's PELs for phosphorus trichloride consistent across all regulated sectors.

POTASSIUM HYDROXIDE CAS: 1310–58–3; Chemical Formula: KOH H.S. No. 1334

OSHA has no limit for potassium hydroxide in the construction, maritime, and agriculture industries. The ACGIH has a TLV* of 2 mg/m³ as a ceiling. NIOSH has no REL for this substance but concurs with the limit being proposed (Ex. 8-47). OSHA is proposing a ceiling limit of 2 mg/m³ for potassium hydroxide in the construction, maritime, and agriculture industries; this is the limit recently established for this substance in general industry.

Potassium hydroxide is a white, deliquescent solid that is available in the form of pellets, sticks, lumps, or flakes. It is used in the manufacture of liquid fertilizers, herbicides, liquid soap, potassium carbonate, and tetra potassium pyrophosphate and as an

absorbent for carbon dioxide and hydrogen sulfide. It is also used in dyestuffs, paint removers, food additives, storage batteries, and fuel cells and in electroplating operations [Hawley's 1987, p. 956; Merck 1963, p. 1102].

In addition to sensory irritation, potassium hydroxide causes tissue destruction of the eyes and skin and, if ingested, rapid corrosion of the esophagus and stomach. The oral LD50 in rats is 273 mg/kg (RTECS 1990). In rabbits and guinea pigs, contact of the skin with 50 mg potassium hydroxide for 24 hours caused severe skin irritation; instilled into rabbit eyes, 1 mg of this substance caused a moderate degree of eye irritation (RTECS 1990). In a skin painting study in mice, tumors identical to those resulting from repeated coal tar applications developed on the skin after 46 weeks of painting with potassium hydroxide (Clayton and Clayton 1981, p. 3056).

Inhalation of potassium hydroxide causes severe irritation of the respiratory tract and leads to sneezing, coughing, and pain (Clayton and Clayton 1981, p. 3056). Repeated exposure may cause perforation of the nasal septum (ACGIH 1986, p. 495). Accidental ingestion of a solution of potassium hydroxide may produce corrosion and perforation of the esophagus and stomach (Clayton and Clayton 1981, p. 3056). Miners exposed to potassium hydroxide concentrations above 2 mg/m3 had the following respiratory symptoms: phlegm production, mild shortness of breath, and chronic cough [Markham JW et al. 1981, AIHAJ 42(9):671). Contact of the eye with potassium hydroxide causes disintegration and sloughing of the conjunctival and corneal epithelium, corneal opacification, edema, and ulceration of the eyes (Grant 1986, p. 756).

Based on this evidence, OSHA preliminarily concludes that exposure to potassium hydroxide causes irritation ranging in degree from mild to chemical pneumonitis (Proctor, Hughes, and Fischman 1988, p. 420); in addition, this substance is corrosive, destroying any tissue it comes into contact with. OSHA believes that these exposure-related effects constitute material health impairments. To substantially reduce these significant risks, OSHA is proposing a ceiling limit of 2 mg/m3 for potassium hydroxide in the construction. maritime, and agriculture industries. Promulgation of this limit will make OSHA's PEL for potassium hydroxide consistent across all OSHA-regulated sectors.

PROPYLENE GLYCOL MONOMETHYL ETHER

CAS: 107-98-2; Chemical Formula: CH₃OCH₂CHOHCH₃ H.S. No. 1343

In the construction, maritime, and agriculture industries, OSHA has no limit for propylene glycol monomethyl ether. The ACGIH has a TLV*-TWA of 100 ppm and a TLV*-STEL of 150 ppm for this substance. NIOSH has no REL. OSHA is proposing an 8-hour TWA of 100 ppm and a 15-minute STEL of 150 ppm for propylene glycol monomethyl ether in the construction, maritime, and agriculture sectors. NIOSH (Ex. 8-47) concurred that these limits were appropriate when the Agency recently established them in general industry.

Propylene glycol monomethyl ether is a flammable, colorless liquid with a characteristic ether-like odor. It is used as a solvent for celluloses, acrylics, dyes, inks, and stains. Propylene glycol monomethyl ether also is used in the solvent-sealing of cellophane.

In addition to sensory irritation, exposure to this substance causes central nervous system depression and liver and kidney effects in experimental animals. The oral LD50 in rats is 5660 mg/kg, and the lowest lethal concentration in the same species is 7000 ppm for 6 hours (RTECS 1990). The dermal LD50 in rabbits lies between 13 and 14 g/kg (Rowe, McCollister, Spencer et al. 1954). Acutely poisoned animals showed central nervous system depression before death (HSDB 1990). Applied to the skin of rabbits, propylene glycol monomethyl ether caused mild irritation, and instillation into rabbit eyes produced the same effect (RTECS 1990). Repeated application of 7 to 10 ml/kg/day propylene glycol monomethyl ether to the skin of rats over a 90-day period caused narcosis and death, while doses of 2 to 4 ml/kg/ day caused only mild narcosis (Rowe, McCollister, Spencer et al. 1954, Arch. Ind. Hyg. Occup. Med. 9:509). Rats and monkeys exposed on 132 of 186 days to a propylene glycol mono-methyl ether concentration of 800 ppm showed no adverse effects, and rats and guinea pigs exposed to a 1500-ppm concentration on 130 of 184 days also showed no adverse effects (Rowe, McCollister, Spencer et al. 1954). Rats given twenty-six 3 g/kg doses of this substance over a 35-day period showed minor liver and kidney effects at autopsy; 1 g/kg doses given on the same regimen produced no gross or histopathological changes (Rowe, McCollister, Spencer et al. 1954).

In humans, exposure to propylene glycol monomethyl ether causes tearing of the eyes at concentrations above 100 ppm (specific concentration not specified) (Stewart, Baretta, Dodd, and Torkelson 1970; Arch. Env. Hlth. 20:218). However, narcotic effects are not seen in exposed individuals until the concentration approaches 100 ppm (Stewart et al. 1970).

Based on this evidence in humans and animals, OSHA preliminarily concludes that exposure to this substance in the workplace is potentially associated with irritant and narcotic effects. The Agency considers effects of this nature material impairments of health and believes that the proposed PELs of 100 ppm as an 8-hour TWA and 150 ppm as a 15-minute STEL are necessary to reduce these significant occupational risks.

Promulgation of these limits will also make OSHA's PELs for propylene glycol monomethyl ether consistent across all OSHA-regulated sectors.

ROSIN CORE SOLDER PYROLYSIS
PRODUCTS

CAS: None; Chemical Formula: None H.S. No. 1350

OSHA has no limit for rosin core solder pyrolysis products, measured as formaldehyde, in the construction, maritime, and agriculture industries. The ACGIH has a TLV²-TWA of 0.1 mg/m³; NIOSH has no REL for this substance. The Agency is proposing an 8-hour TWA of 0.1 mg/m³ for rosin core pyrolysis products in the construction, maritime, and agriculture industries. This is the limit recently promulgated for this substance in general industry.

Rosin is a pale yellow to amber, translucent solid that consists of about 90 percent resin acids and 10 percent neutral material. Gum rosin is used as a soldering flux, and soldering with this substance or a solder that contains it causes the release of thermal decomposition products (ACGIH 1986, p. 514). The pyrolysis products of rosin core solder include acetone, methyl alcohol, aldehydes, carbon monoxide and dioxide, methane, ethane, abietic acid, and related diterpene acids (ACGIH 1986, p. 514).

Exposure to these products causes marked irritation of the eyes, nose, and throat (Cralley and Cralley 1985, p. 180). A 2-week exposure of guinea pigs and rats to these products at average concentrations of 0.96 mg/m³ caused a reduction in the rate of weight gain in male guinea pigs, abnormal liver-to-body-weight ratios in guinea pigs of both sexes, and abnormal heart-to-body-weight ratios in male rats; at autopsy, the lungs of these animals were hyperemic (Industrial Bio-test Laboratories, Inc. 1967, as cited in ACGIH 1986/Ex. 1–3, p. 514).

In humans, slight bronchial irritation has been reported on exposure to a rosin core pyrolysis product concentration of 1 mg/m3 or below (Industrial Bio-test Laboratories, Inc. 1967, as cited in ACGIH 1986/Ex. 1-3, p. 514). Several workers who were chronically exposed to pyrolysis product levels as high as 0.15 mg/m3 had to be removed from exposure because of intractable upper respiratory tract irritation; when concentrations were kept below 0.10 mg/m3, such irritation was not reported (Christy 1965, as cited in ACGIH 1986/Ex. 1-3, p. 514). In a study designed to quantify doseresponse levels for irritation in human volunteers, subjects were exposed for 15 minutes to these products at aldehyde concentrations (measured as formaldehyde, which is the best indirect measure of rosin pyrolysis products) of 0.04 to 0.2 mg/m3 (U.S. Public Health Service 1965, as cited in ACGIH 1986/ Ex. 1-3, p. 514). Subjects detected the odor at 0.07 mg/m3, and 80 percent of subjects reported moderate to severe irritation of the eyes, nose, and throat at concentrations of 0.12 mg/m3 or above. At levels below 0.05 mg/m3, fewer than 10 percent of subjects experienced irritation. Mucous membrane irritation occurred in 30 percent of subjects exposed to a concentration of 0.07 mg/ m3 (U.S. Public Health Service 1965, as cited in ACGIH 1986/Ex. 1-3, p. 514).

Based on this evidence, OSHA is proposing an 8-hour TWA limit of 0.1 mg/m³, measured as formaldehyde, for rosin core solder pyrolysis products in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that this limit is necessary to protect employees in these sectors from the significant risk of eye, nose, and throat irritation that is associated with exposure to these pyrolysis products. Promulgation of this limit will also make OSHA's PELs for this substance consistent across all OSHA-regulated sectors.

SODIUM BISULFITE CAS: 7631–90–5; Chemical Formula: NaHSO₃

H.S. No. 1365

OSHA has no limit for sodium bisulfite in construction, maritime, and agricultural workplaces. The ACGIH has a TLV*-TWA of 5 mg/m³, NIOSH has no REL for this substance. The Agency is proposing a limit of 5 mg/m³ as an 8-hour TWA in the construction, maritime, and agriculture industries. NIOSH (Ex. 8-47) agreed with the selection of this limit when OSHA recently established it in general industry.

Sodium bisulfite is a white crystalline powder that has an odor like that of sulfur dioxide. It is used as a food preservative (particularly as a lettuce freshener in salad bars) and as a reducing agent, analytical reagent, dietary supplement, and color preservative for pale crepe paper. It is also used in cask sterilization, fermentation, textiles, and copper and brass plating and to bleach groundwood (Hawley's 1987, p. 1054).

In addition to sensory irritation, sodium bisulfite causes central nervous system effects in animals and humans. The oral LD50 in rats is 2 g/kg (Dow Chemical Company 1977d, as cited in ACGIH 1986/Ex. 1-3, p. 534), and the intraperitoneal LD50 in rats is 475 mg/kg (RTECS 1990). Animals acutely poisoned by intraperitoneal administration convulsed and had altered sleep times (RTECS 1990). In other acute poisonings, death is preceded by irritability, restlessness, convulsions, periods of apnea, terminal respiration, and cardiovascular collapse (Gosselin, Smith, and Hodge 1984, p. II-123).

In humans, sodium bisulfite causes eye and mucous membrane irritation, dermatitis, and sensitization reactions. Industrial exposure to unspecified concentrations of sodium bisulfite has caused irritation of the eyes and respiratory tract that was described as mild (ACGIH 1988, p. 534). A recent study (Howland WC, Simon RA, J. Allergy, Clin. Immunol. 83(6):1079-1082, 1989) has shown that sodium bisulfitetreated lettuce is capable of provoking bronchospasm in sulfite-sensitive individuals who have asthma. Another study has shown that a worker exposed to sodium bisulfite during the preparation of animal feed developed acute dermatitis on the exposed areas of his body (face, neck, hands, and forearms); positive patch tests confirmed that sodium bisulfite was the allergen (Dinis, Brandao, and Faria 1988; Contact Dermatitis 18(3):170-171).

Based on this evidence in humans and animals, OSHA preliminarily finds that exposure to sodium bisulfite presents a significant occupational risk of irritation, dermatitis, and sensitization, and that these effects constitute material impairments of health. To substantially reduce these risks, OSHA believes it necessary to establish a 5mg/m38-hour TWA for sodium bisulfite in construction, maritime, and agriculture workplaces, and this is the limit being proposed. Promulgation of this limit will make the PEL for this substance consistent across all OSHAregulated sectors.

SODIUM HYDROXIDE

CAS: 1310–73–2; Chemical Formula: NaOH H.S. No. 1367

OSHA has an 8-hour TWA of 2 mg/m³ for sodium hydroxide in the construction and maritime industries. The ACGIH TLV® is a ceiling limit of 2 mg/m³, and NIOSH currently has a REL for this substance of 2 mg/m³ as a 15-minute ceiling short-term limit. OSHA is proposing a 2-mg/m³ ceiling limit for sodium hydroxide in the construction, maritime, and agriculture industries. NIOSH (Ex. 8-47) concurred with this limit when OSHA recently established it in general industry.

Sodium hydroxide is a white, deliquescent solid used in the manufacture of chemicals, as a neutralizing agent in petroleum refining, and as an ingredient in detergents and soaps. This substance is also widely used in textile processing, vegetable oil refining, and the reclamation of rubber. In addition, sodium hydroxide is used for regenerating ion exchange resins, in organic fusions, as a lab reagent, in etching and electroplating, and as a food additive (ACGIH 1986, p. 535; Hawley's 1987, p. 1062).

Sodium hydroxide is a severe irritant of the eyes, mucous membranes, and skin. In addition to sensory irritation, sodium hydroxide destroys tissue on contact. The lowest lethal oral dose in rabbits is 500 mg/kg (RTECS 1990). A 1percent solution of sodium hydroxide instilled into the eyes of monkeys caused severe eye irritation, and 500 mg placed on the skin of rabbits caused severe skin irritation (RTECS 1990). Two of 10 rats exposed for 30 minutes twice a week to an aerosol of 40 percent aqueous sodium hydroxide whose particles were less than 1 um in diameter died after 3 weeks. Histopathological examination showed mostly normal lung tissue with foci of enlarged alveolar septae, emphysema,

bronchial ulceration, and enlarged

lymph adenoidal tissues (Wands 1981b,

in Clayton and Clayton 1982, p. 3062). Although the inhalation of sodium hydroxide is usually of secondary importance in industrial exposures, the effects of inhaling the dust or mist vary from mild irritation of the nose, which occurs on brief exposure to 2 mg/m3, to severe pneumonitis and ulceration of the nasal septum, which may occur at very high (but not further specified) exposures (Proctor, Hughes, and Fischman 1988, p. 444; ACGIH 1986, p. 535). The greatest industrial hazard is rapid tissue destruction of the eyes or skin upon contact either with the solid or with concentrated solutions (Proctor, Hughes, and Fischman 1988, p. 444).

Contact of sodium hydroxide with the eyes causes disintegration and sloughing of the conjunctival and corneal epithelium, corneal opacification, marked edema, and ulceration; after 7 to 13 days, gradual recovery may begin or the lesion may progress to ulceration and corneal opacification. In severe eye burns, symblepharon, with overgrowth of the comea by a vascularized membrane, progressive or recurrent corneal ulceration, and permanent corneal opacification may occur (Proctor, Hughes, and Fischman 1988, p. 444). Grant (1986/Ex. 1-975) states that sodium hydroxide causes "some of the most severe, blinding injuries of the eye." On the skin, solutions of 25 to 50 percent sodium hydroxide cause a sensation of irritation within about 3 minutes; with solutions of 4 percent, the sensation of burning does not occur until several hours later. If not removed from the skin, sodium hydroxide causes severe burns and deep ulcerations. Exposure to the dust or mist of sodium hydroxide may cause multiple small burns, with temporary loss of hair (Proctor, Hughes, and Fischman 1988, p. 445). Nagao and co-workers (1972) examined skin biopsies from volunteers who had a 1 N solution (equal to a 4percent solution) of sodium hydroxide applied to their arms for 15 to 180 minutes. Progressive changes, beginning with dissolution of the cells in the horny layer and progressing through edema to total destruction of the epidermis, occurred in these individuals within 60 minutes (Nagao, Stroud, Hamada et al.

The irritant effect of sodium hydroxide and its markedly corrosive action on all body tissue can result even from brief (one minute or more) exposures to airborne concentrations above the 2-mg/m3 level; the acute nature of these effects is evident in the studies described above. Based on this evidence, OSHA preliminarily concludes that establishing a ceiling of 2 mg/m3 in the construction, maritime, and agriculture industries is necessary to reduce the significant risks of eye and skin burns and respiratory irritation that occur even on brief exposure to sodium hydroxide. OSHA considers the irritant effects resulting from exposure to sodium hydroxide material impairments of health and is accordingly proposing a ceiling limit of 2 mg/m3 for sodium hydroxide in the construction, maritime, and agriculture industries. Promulgation of this PEL will make the limit for sodium hydroxide consistent across all OSHA-regulated sectors.

SODIUM METABISULFITE

CAS: 7681-57-4; Chemical Formula: Na₂S₂O₅ H.S. No. 1368

OSHA has no exposure limit for sodium metabisulfite in the construction, maritime, and agriculture industries. The ACGIH has an 8-hour TLV*-TWA of 5 mg/m³, NIOSH has no REL for this substance. The Agency is proposing a 5-mg/m³ TWA for sodium metabisulfite in the construction, maritime, and agriculture industries. NIOSH (Ex. 8-47) concurred with the selection of this limit when OSHA established it in general industry.

Sodium metabisulfite can occur either in the form of a solid block or as white crystals; this substance smells like sulfur dioxide. Sodium metabisulfite is used as a preservative, in the manufacture of pharmaceuticals and foods, and as a lab reagent (HSDB 1989).

A 2-year study conducted by the Dow Chemical Company (1977e, as cited in ACGIH 1986/Ex. 1-3, p. 535), in which rats ingested 0.215 percent sodium metabisulfite, demonstrated that oral administration of sodium metasulfite caused no adverse effects in the rats. The LD₅₀ in rats is 115 mg/kg by intravenous administration (RTECS 1990). Oral administration of sodium metabisulfite to rats at doses of 20 mg/kg or 40 mg/kg produced stillbirths or other adverse effects on the offspring (RTECS 1990).

In humans, inhalation of the dust of sodium metasulfite causes mucous membrane and sensitization effects similar to those that caused by sodium bisulfite (ACGIH 1986, p. 535; Nichol, Nix, Chung, and Barnes 1989, in Thorax 44(12):1009-1014). Fifteen of 18 asthmatic and atopic volunteers who were challenged with sodium metabisulfite developed bronchoconstriction of sufficiently severe degree to cause a 20-percent reduction from baseline levels in forced expiratory volume in one second (FEV1) (Nichol, Nix, Chung, and Barnes 1989). In addition, prolonged or repeated exposure to the dust of this substance causes dermatitis (Hazardous Substance Fact Sheet 1985, p. 2).

Based on this evidence in humans and animals, OSHA is proposing an 8-hour TWA of 5 mg/m³ for sodium metabisulfite in the construction, maritime, and agriculture industries. The Agency preliminarily finds that establishing this limit is necessary to reduce the risk of eye and skin irritation and pulmonary sensitization associated with exposure to high concentrations of sodium metabisulfite dust. OSHA has preliminarily determined that these effects constitute material impairments

of health. Accordingly, OSHA is proposing a 5-mg/m³ limit as an 8-hour TWA for this substance; promulgation of this limit will make the PELs for this substance consistent across all OSHA-regulated sectors.

SULFUR MONOCHLORIDE CAS: 10025-67-9; Chemical Formula: S₂Cl₂

H.S. No. 1376

OSHA's PEL for sulfur monochloride in the construction and maritime industries is 1 ppm as an 8-hour TWA. There is no PEL in agriculture. The ACGIH has a TLV* of 1 ppm as a ceiling limit, and NIOSH has no REL for this substance. The Agency is proposing to revise its limit for sulfur monochloride in the construction and maritime industries to a 1 ppm ceiling and to extend this limit to agriculture. NIOSH (Ex. 8-47) concurred with this limit when OSHA recently established it for general industry.

Sulfur monochloride is an amber, oily, nonflammable, fuming liquid that has a penetrating odor. It is used in the manufacture of insecticides, to vulcanize rubber, in chemical synthesis, to harden wood, in textile finishing, and in gold extraction. Sulfur monochloride is also used as a polymerization catalyst for vegetable oils (ACGIH 1986, p. 545;

Merck 1983, p. 1288).

In addition to sensory irritation, exposure to sulfur monochloride can lead to burns of the eyes and skin. Sulfur monochloride is a primary irritant that affects the upper respiratory tract by releasing hydrochloric acid (HCl) on contact with moisture (Henderson and Haggard 1943g, as cited in ACGIH 1986/ Ex. 1-3, p. 545). Animal toxicity studies revealed that mice exposed to a 150-ppm concentration of sulfur monochloride died after 1 minute (Flury and Zernik 1931k/Ex. 1-979). Cats exposed for 15 minutes to 60 ppm sulfur monochloride all died within a few days, but exposure to a concentration of 12 ppm for 15 minutes was tolerated by these animals (Henderson and Haggard 1943g, as cited in ACGIH 1986/Ex. 1-3, p. 545).

In humans, sulfur monochloride causes tearing of the eyes and coughing; if the exposure is severe, pulmonary edema may develop (Proctor, Hughes, and Fischman 1988, p. 454). Splashed into the eyes, this substance causes severe damage and may cause permanent scarring; in contact with the skin, it causes burns (ACGIH 1986, p. 545). A study by Elkins (1959g, as cited in ACGIH 1986/Ex. 1–3, p. 545) of workers in the rubber industry found that exposure to sodium monochloride concentrations of 2 to 9 ppm was mildly irritating; however, because of moisture

in the air, the concentrations to which these workers were exposed may have included a high proportion of hydrochloric acid.

Based on this evidence, the Agency preliminarily concludes that workers in the construction, maritime, and agriculture industries are at significant risk from the primary irritation that could occur even on short-term exposure to elevated concentrations of sulfur monochloride. Since 2 ppm is reported to be an effect level for mild irritation. OSHA preliminarily finds that revising its 8-hour TWA limit in construction and maritime to 1 ppm as a ceiling and extending this ceiling limit to agriculture is a reasonable and necessary action to protect workers in these sectors from the significant risk of sensory irritation, which constitutes a material impairment of health. Therefore, OSHA is proposing a ceiling limit for sulfur monochloride of 1 ppm in the construction, maritime, and agricultural sectors. Promulgation of this limit will also make the PEL for this substance consistent across all OSHAregulated sectors.

SULFUR PENTAFLUORIDE CAS: 5714-22-7; Chemical Formula: S₂F₁₀ H.S. No. 1377

OSHA's limit for sulfur pentafluoride in construction and maritime workplaces is 0.025 ppm as an 8-hour TWA. There is no PEL in agriculture. The ACGIH has a ceiling limit for sulfur pentafluoride of 0.01 ppm, and NIOSH has no REL for this substance. The Agency is proposing a 0.01 ppm ceiling limit for sulfur pentafluoride in construction, maritime, and agriculture. NIOSH concurred (Ex. 8-47) with this limit when OSHA recently established it for general industry.

Sulfur pentafluoride is a colorless gas or liquid with a sulfur dioxide-like odor. Sulfur pentafluoride is used as a reactant in research applications (Genium MSDS 1989, No. 262).

Sulfur pentafluoride causes severe respiratory tract irritation in animals. The LC50 in rats is 0.2 ppm for 10 minutes; in monkeys, the LC50 is 0.9 ppm for 10 minutes (RTECS 1990). Saunders, Shoshkes, DeCarlo, and Brown (1953/ Ex. 1-610) established that the intravenous LD50 for sulfur pentafluoride in rabbits is 5.8 mg/kg, and that death was due to fulminant pulmonary edema. In a study in which rats were exposed to sulfur pentafluoride for 16 to 18 hours, concentrations of 0.1 ppm caused lung irritation, 0.5 ppm resulted in severe pulmonary lesions, and 1 ppm proved fatal (Greenberg and Lester 1950/Ex. 1-590). One-hour exposures to 10 ppm

sulfur pentafluoride caused diffuse hemorrhagic lesions in the lungs of rats, and 1-hour exposures to 1 ppm caused severe congestion of the lungs. Rats exposed for one hour to 0.1 ppm showed no effects. Subsequent examination of rats surviving the 10- and 1-ppm exposures revealed that the lungs had returned to normal after 24 hours (Greenberg and Lester 1950/Ex. 1-590). Dogs exposed intravenously to a 1-mg/ kg dose of sulfur pentafluoride experienced vascular shock and died from acute pulmonary edema (RTECS 1989). There are no reports of human exposure to sulfur pentafluoride.

Based on this evidence, OSHA is proposing to revise the sulfur pentafluoride limit in construction and maritime to 0.01 ppm as a ceiling and to extend this limit to agriculture. The 0.01ppm ceiling is appropriate because of evidence showing that even brief exposures to 1 ppm caused pulmonary effects and prolonged exposures to 0.1 ppm caused lung irritation in animals. OSHA preliminarily concludes that this limit is necessary to substantially reduce the risks of irritation and other pulmonary effects potentially associated with exposure to this substance. The Agency considers these effects material impairments of health. Promulgation of a 0.01 ppm ceiling for sulfur pentafluoride will make OSHA's PEL for this substance consistent across all regulated sectors.

SULFURIC ACID
CAS: 7664-93-9; Chemical Formula:
H₂SO₄
H.S. No. 2147

In general industry, construction, and maritime, OSHA's permissible exposure limit for sulfuric acid is 1 mg/m³ as an 8-hour TWA. There is no limit in agriculture. The ACGIH has an 8-hour TLV*-TWA of 1 mg/m³ and a TLV*-STEL of 3 mg/m³. NIOSH has a REL of 1 mg/m³ and concurs (Ex. 8-47) with the limit being proposed. OSHA is proposing to establish an 8-hour TWA limit of 1 mg/m³ for sulfuric acid in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Sulfuric acid is a dense, oily, colorless, odorless liquid. This substance is the most widely used of all industrial chemicals, finding use in the manufacture of fertilizers, chemicals, plastics, and explosives. in metal cleaning, petroleum refining, in the pickling of metal, and in electroplating (ACGIH 1986, p. 544(87); Proctor, Hughes, and Fischman 1988, p. 451).

Sulfuric acid is a severe irritant of the eyes, skin, mucous membranes, and

respiratory tract in humans and animals; this substance also causes dental erosion. The oral LD50 in rats is 2140 mg/ kg (RTECS 1990). In rats and mice, the 2hour LC50s are 510 mg/m3 and 320 mg/ m3, respectively (RTECS 1990). Guinea pigs are more sensitive to sulfuric acid effects than rats, mice, or rabbits: exposure to a sulfuric acid concentration of 87 mg/m3 for 2.75 hours killed guinea pigs, but rats, mice, and rabbits survived exposure to 203 mg/m3 for 7 hours (Treon, Dutra, Cappel et al. 1950, in ACGIH 1986, p. 544(87)). Rabbits showed severe eye irritation after 5 mg of sulfuric acid was instilled into their eyes, followed after 30 seconds by rinsing (RTECS 1990). Guinea pigs exposed continuously for 24 hours/day tolerated sulfuric acid concentrations as high as 4 mg/m3 for as long as 140 days; at autopsy, signs of pulmonary pathology were seen (Thomas et al. 1958, in ACGIH 1986, p. 544(87)). Monkeys exposed continuously for 2 years to concentrations of sulfuric acid between 0.1 and 1 mg/m3 developed increasingly severe pulmonary lesions; exposure to a concentration of 2.5 mg/ m3 caused impairment of pulmonary ventilation (Alarie et al. 1975, in Proctor, Hughes, and Fischman 1988, p. 453).

The lowest lethal oral dose in humans is estimated to be 135 mg/kg; the lowest reported toxic concentration is 3 mg/m3 for 24 weeks (RTECS 1989). In an experiment designed to determine thresholds for irritant effects, subjects reported throat tickling and scratching at a mean minimum concentration of 0.72 mg/m3, considerable irritation at the base of the esophagus and eye irritation at 1.1 to 2.1 mg/m3, and acute irritation of the eyes and mucous membranes and reflex coughing at concentrations between 2.4 and 6.0 mg/ m3. Exposure to a sulfuric acid concentration of 1.0 to 1.1 mg/m3 caused slight changes in respiration, and increasing the concentration to 1.8 to 2.0 mg/ms produced changes in respiratory amplitude and rhythm in all subjects (NIOSH Criteria Document 1974). A worker sprayed in the face with fuming sulfuric acid suffered skin burns and pulmonary edema (NIOSH Criteria 1974). When splashed in the eye, concentrated sulfuric acid causes severe damage and may cause blindness; a splash of dilute sulfuric acid produces transient effects (Grant 1986, pp. 866-868). Corrosion of the dental enamel has been seen in some sulfuric acid plant workers and in battery plant workers (Premysl 1952; Malcolm and Paul 1961, in ACGIH 1986, p. 544(87)). Exposure to an average concentration of 0.23 mg/m3 sulfuric acid caused a high incidence of teeth etching and erosion; these effects

occurred after 4 months of exposure (Gamble et al. 1984, in HSDB 1990). Workers chronically exposed to sulfuric acid may develop signs and symptoms such as skin lesions, tracheobronchitis, stomatitis, conjunctivitis, and gastritis (Raule 1955, in ACGIH 1986, p. 544(87)). A total of 225 lead acid battery plant workers were studied using industrial hygiene measurements (personal samples), a symptom questionnaire, and spirometry. In acclimated workers, there was no evidence of acute symptoms or of declines in pulmonary function when the concentration of sulfuric acid was kept below 1 mg/m3 (Gamble et al. 1984. in Environ. Res. 35(1):11-29). A recent epidemiology study suggests that exposure to higher (not further specified) concentrations of sulfuric acid is associated with an excess risk of upper respiratory tract cancer, and specifically with laryngeal cancer (Soskoline et al. 1984, in Am. J. Epidemiol. 120(3):358-

Based on this evidence in humans and animals, OSHA preliminarily concludes that exposure to sulfuric acid causes severe eye, skin, and respiratory irritation, and corrosion of the dental enamel of the teeth. OSHA preliminary concludes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse exposure-related effects. The Agency believes that the proposed 8-hour TWA limit of 1 mg/m3 for sulfuric acid is necessary to substantially reduce the risks of these material health impairments. Extension of this limit to the agricultural sector will make OSHA's PEL for sulfuric acid consistent across all regulated sectors.

TETRAHYDROFURAN
CAS: 109–99–9; Chemical Formula:
(C₂H₄)₂O
H.S. No. 1387

OSHA's PEL for tetrahydrofuran in construction and maritime workplaces is 200 ppm as an 8-hour TWA. There is no PEL in agriculture. The ACGIH has a 200 ppm TLV*-TWA and a 250 ppm TLV*-STEL for tetrahydrofuran. The Agency is retaining the 8-hour TWA PEL of 200 ppm in the construction and maritime industries and is proposing to extend it to agricultural workplaces; in addition, OSHA is proposing to add a 250-ppm STEL for tetrahydrofuran in the construction, maritime, and agriculture industries. NIOSH (Ex. 8-47) concurred that these limits were appropriate when OSHA recently established them in general industry.

Tetrahydrofuran is a colorless liquid with an odor like that of ether. This substance is used as a solvent for natural and synthetic resins and in lithium aluminum hydride reduction and polymerization. It is also a chemical intermediate (ACGIH 1986, p. 564).

In addition to sensory irritation, tetrahydrofuran causes central nervous system depression in animals and humans. The oral LD50 in rats is 2816 mg/kg, and the LCso in the same species is 21,000 ppm for 3 hours (RTECS 1990). Lehmann and Flury (1943c/Ex. 1-879) reported that animals exposed to concentrations of tetrahydrofuran exceeding 3000 ppm for 8 hours/day for 20 days showed signs of irritation of the upper respiratory tract as well as kidney and liver injury. Applied to the skin of rabbits, aqueous solutions of tetrahydrofuran that exceeded 20 percent caused irritation. One study (Stoughton and Robbins 1936/Ex. 1-597) found that tetrahydrofuran concentrations in excess of 25,000 ppm were needed to anesthetize dogs. The anesthesia process in these animals showed a delayed induction period and poor recovery. In other studies with dogs (Zapp 1971, as cited in ACGIH 1986/Ex. 1-3, p. 564), exposure to a 200ppm concentration of tetrahydrofuran for 6 hours produced an observable effect on the pulse pressure of these animals within three to 4 weeks; however, despite exposure to this concentration for 9 weeks, followed by exposure for 3 weeks to nearly twice this concentration, no histopathologic changes were observed in the critical organs at autopsy. The work of Jochmann (1961/Ex. 1-1021), in which tetrahydrofuran was given orally and peritoneally to a variety of laboratory animals, showed both liver and kidney damage in these animals at autopsy; however, some of the effects observed by this author may have been caused by peroxide contamination of the tetrahydrofuran. Rats and mice were exposed for 13 weeks to concentrations of 66, 200, 600, 1800, or 5000 ppm. Rats exposed to 5000 ppm became ataxic, and mice exposed to 1800 or 5000 ppm became narcotic. At autopsy, minimal exposure-related effects were seen in the livers of both mice and rats in the high-dose group; however, morphologic changes were seen only in the high-dose mice (Chabra, Elwell, Chou, Miller, and Renne 1990, in Funda. Appl. Toxicol. 14(2):338-345).

In humans, exposure to tetrahydrofuran at a concentration of 25,000 ppm causes anesthesia (RTECS 1990). The symptoms of overexposure that have been reported in humans include headache, nausea, and dizziness, all indicative of central nervous system depression (AIHA 1959).

The technicians involved in the experiment described above involving the anesthetization of dogs (Stoughton and Robbins 1936/Ex. 1-597) developed severe occipital headaches as a result of their exposure. Two plumbers exposed to unspecified concentrations of tetrahydrofuran when they were repairing pipes with glue containing this substance developed mucous membrane irritation, mild central nervous system effects, and toxic hepatitis, as evidenced by elevated liver enzymes. The enzymes returned to normal values within 14 days of the exposure (Garnier, Rosenberg, Puissant, Charvet, and Efthymion 1989).

Based on this evidence in humans and animals, OSHA preliminarily concludes that the proposed PELs of 200 ppm as an 8-hour TWA and 250 ppm as a 15-minute STEL are necessary to substantially reduce the significant risk of irritation and central nervous system depression associated with exposure to tetrahydrofuran. The Agency believes that these adverse health effects constitute material impairments of health. Promulgation of these limits for the construction, maritime, and agriculture industries will make OSHA's PELs for tetrahydrofuran consistent across all OSHA-regulated sectors. TETRANITROMETHANE CAS: 509-14-8 H.S. No. 2157

OSHA's PEL for tetranitromethane in general industry, construction, and maritime is 1 ppm as an 8-hour TWA; there is no limit in agriculture. The ACGIH TLV®-TWA for tetranitromethane is 1 ppm; there is no NIOSH REL for this substance. OSHA is proposing a TWA PEL of 1 ppm for tetranitromethane in agriculture. This is the limit recently established for this substance in general industry.

Tetranitromethane is a colorless to pale-yellow liquid with an acrid, biting odor. It is used as an oxidizing agent in rocket propellants, in explosives, as a diesel fuel additive, and as a laboratory reagent. It has been proposed for use as an irritant war gas (HSDB 1989; Clayton and Clayton 1981, p. 4157; ACGIH 1986,

Tetranitromethane is a severe irritant of the eyes and respiratory tract in both animals and humans; at high concentrations, it causes methemoglobinemia and central nervous system damage. The oral LD50 in rats is 130 mg/kg; the 4-hour LC50 in the same species is 18 ppm (RTECS 1989). Rats exposed to 1230 ppm for 36 minutes exhibited lacrimation, rhinorrhea, gasping, and cyanosis before death; autopsy revealed pulmonary edema

(Horn 1954). Cats exposed to a 0.1 to 0.4 ppm concentration of tetranitromethane showed signs of mild eye irritation, and cats exposed to a 10-ppm concentration of tetranitromethane for 20 minutes exhibited illness and died 10 days after exposure (AIHA 1964; Flury and Zernik 1931). A concentration of 33 ppm killed 65 percent of rats exposed for 6.5 hours, and 58 percent of rats exposed to a 6.35ppm concentration for 6 hours/day, 5 days/week for 6 months died. Autopsy of the chronically exposed animals revealed lung damage (Horn 1954). Intravenous injection of tetranitromethane resulted in methemoglobinemia, anemia, central nervous system damage, and pulmonary edema in three species of experimental animals (Horn 1954).

In humans, the lowest lethal dose of tetranitromethane by inhalation is estimated to be approximately 500 mg/ kg (or about 35 grams); the few deaths and poisonings that have occurred in workers handling heated trinitrotoluene (TNT) have been attributed to tetranitromethane contamination of the TNT (Clayton and Clayton 1982, p. 4157). Laboratory workers manufacturing tetranitromethane have reported experiencing irritation of the eyes, nose, and respiratory passages: dizziness; headache; chest pain; dyspnea; and, rarely, skin irritation (Horn 1954). In contact with the skin, tetranitromethane causes mild burns (AIHA 1964).

Based on this evidence in humans and animals, OSHA preliminarily concludes that agricultural workers exposed to this substance at the levels permitted by the absence of a permissible exposure limit are at significant risk of experiencing irritation of the eyes and respiratory tract. At high concentrations, they may also be at risk of death. The Agency believes that establishing a PEL of 1 ppm as an 8-hour TWA will protect workers in agriculture from these significant risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. TETRASODIUM PYROPHOSPHATE CAS: 7722-88-5; Chemical Formula:

Na₄P₂O₇ H.S. No. 1389

OSHA has no limit for tetrasodium pyrophosphate in the construction, maritime, or agriculture industries. The ACCIH has an 8-hour TLV®-TWA of 5 mg/m3; NIOSH has no REL for this substance but concurs that the proposed limit is appropriate (Ex. 8-47). OSHA is proposing an 8-hour TWA limit of 5 mg/ m3 for this substance in the

construction, maritime, and agriculture industries; this is the limit recently established for tetrasodium pyrophosphate in general industry.

Tetrasodium pyrophosphate is a white powder or a crystalline solid. This substance is used as a water softener, in soaps and detergents, as a dispersing and emulsifying agent, as a metal cleaner, and as a nutrition supplement. Tetrasodium pyrophosphate is also used in boiler water treatment, in drilling muds, dyeing, wood scouring, and as a sequestrant (ACGIH 1986, p. 567).

In addition to sensory irritation, tetrasodium pyrophosphate causes kidney damage in experimental animals exposed subchronically by oral administration. The oral LD₅₀ in rats is 4000 mg/kg (RTECS 1990). Administered to rats in the diet for 4 to 6 months, all dietary levels exceeding 1 percent tetrasodium pyrophosphate caused kidney damage (HSDB 1989).

In humans, exposure to the alkaline dust of tetrasodium pyrophosphate is associated with irritation of the eyes and respiratory passages (Dow Chemical Co. 1977, in ACGIH 1986, p. 567). Contact of this substance with the skin of humans causes irritation (Hazardous Substance Fact Sheet 1986, p. 2). Ingestion of this substance can cause nausea, vomiting, and diarrhea (Gosselin, Smith, and Hodge 1984, p. II–121).

Based on this evidence, OSHA preliminarily concludes that exposure to this substance poses a significant risk of eye, skin, and respiratory tract irritation to workers in the construction, maritime, and agriculture industries. The Agency believes that these effects represent material impairments of health. Accordingly, OSHA is proposing a 5-mg/m³ 8-hour TWA limit for tetrasodium pyrophosphate in the construction, maritime, and agriculture industries; promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

THIOGLYCOLIC ACID
CAS: 68-11-1; Chemical Formula:
C₂H₄O₂S
H.S. No. 1392

OSHA has no PEL for thioglycolic acid in the construction, maritime, or agriculture industries. The ACGIH has a TLV*-TWA of 1 ppm, with a skin notation. NIOSH has no REL for this substance. The Agency is proposing a 1 ppm TWA, and a skin notation, for thioglycolic acid in the construction, maritime, and agricultural industries. NIOSH (Ex. 8-47) concurred with this limit when OSHA recently established it in general industry.

Thioglycolic acid is a colorless, combustible liquid with the unpleasant odor characteristic of chemicals in the sulfhydryl group. Thioglycolic acid is used in the manufacture of pharmaceuticals, thioglycolates, permanent wave solutions, and depilatories and as a vinyl stabilizer (ACGIH 1986, p. 571).

In addition to sensory irritation, thioglycolic acid causes central nervous system effects in experimental animals. The oral LD50 in rats is 114 mg/kg. The lowest lethal concentration in mice is 7 mg/m3 (1.9 ppm) for 2 hours (RTECS 1990). The lowest lethal concentration in rabbits by skin absorption is 300 mg/kg (RTECS 1990). The dermal LD50 for a 10 percent solution of thioglycolic acid is 848 mg/kg (ACGIH, 1986, p. 571/Ex. 1-3). A 5-ml/kg dermal dose of a 10percent solution of thioglycolic acid caused weakness, gasping, and convulsions in guinea pigs. After receiving an oral dose of 125 mg/kg, female rats died; autopsy revealed liver effects and signs of gastrointestinal irritation (Dow Chemical Co. 1973b, as cited in ACGIH 1986, p. 571). Rabbits experienced conjunctival inflammation. dense corneal opacity, and iritis after thioglycolic acid was instilled into their eyes. The substance is also a severe skin irritant in animals (HSDB 1989).

In humans, contact of the skin or eyes with thioglycolic acid causes severe burns and blistering (Merck 1983, p. 1337). Hairdressers exposed to thioglycolates in permanent wave solutions have reported developing eczematous rashes on the face, scalp, and hands after contact with these materials (HSDB 1989). One accident has been reported in which a person was splashed in the eyes and on the face, legs, and arms with concentrated thioglycolic acid and subsequently experienced second-degree burns of the skin. The less injured eye returned to normal quickly, but the conjunctiva in the other eye became necrotic and the corneal became clouded. Most of this damage eventually cleared, and the victim was left with only a slight opacity in one eye (Grant 1986, p. 905).

Based on this evidence in humans and animals, OSHA preliminarily concludes that thioglycolic acid poses a significant risk of eye and skin burns and irritation, effects that constitute material impairments of health. OSHA believes that the proposed 1-ppm 8-hour TWA limit for this substance is necessary to reduce these risks for workers in the construction, maritime, and agricultural industries. In addition, because evidence in animals shows that thioglycolic acid solutions readily penetrate the skin, OSHA preliminarily finds that a skin

notation is necessary to limit dermal contact. Promulgation of the proposed limit and the skin notation will make OSHA's PEL for this substance consistent across all OSHA-regulated sectors.

1,2,4-TRICHLOROBENZENE
CAS: 120-82-1; Chemical Formula:
C₆H₃Cl₃
H.S. No. 1405

OSHA has no limit for 1,2,4-trichlorobenzene in the construction, maritime, or agriculture industry. The ACGIH has a TLV* ceiling limit of 5 ppm for 1,2,4-trichlorobenzene; NIOSH has no REL for this substance. OSHA is proposing a 5-ppm ceiling limit for this substance in the construction, maritime, and agricultural industries. NIOSH (Ex. 8-47, Table N1) concurred that the proposed limit was appropriate when the Agency recently established it in general industry.

1,2,4-Trichlorobenzene is a colorless, stable liquid at room temperature; it has an aromatic odor. 1,2,4Trichlorobenzene is used as an insecticide, as a dielectric fluid, and as a heat transfer medium. It is also used in lubricants and in organic synthesis (ACGIH 1986, p. 593). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

In addition to sensory irritation, 1,2,4trichlorobenzene causes central nervous system effects and liver and kidney damage in experimental animals. The oral LD50 in rats is 756 mg/kg (RTECS 1990), and the acute percutaneous LDse in rats is 6139 mg/kg (Brown, Muir, and Thorpe 1969/Ex. 1-537). Sublethal doses administered repeatedly to guinea pigs caused liver damage; acute and shortterm exposure (fifteen 6-hour exposures to concentrations between 70 and 200 ppm), however, failed to kill these animals (Gage 1970/Ex. 1-318). The inhalation toxicity of 1,2,4 trichlorobenzene was studied by Treon (1950, as cited in ACGIH 1986/Ex. 1-3, p. 593), who determined that the target organs of exposure in cats, dogs, rats, rabbits, and guinea pigs included the liver, kidneys, ganglion cells at all brain levels, and mucous membranes. Irritation of the lungs and changes in respiration were seen in those animals that later died as a result of exposure. In a separate study conducted by Rowe (1975, as cited in ACGIH 1986/Ex. 1-3, p. 593), 20 male rats, 4 rabbits, and 2 dogs were exposed to 1,2,4-trichlorobenzene at concentrations of 30 or 100 ppm for 7 hours/day, 5 days/week for a total of 30

exposures in 44 days. No adverse exposure-related effects were detected in exposed animals in the 30-ppm group, with the exception of an elevation of urinary porphyrins in the rats on days 15 and 30 of exposure. A second inhalation study involved exposure to 1,2,4trichlorobenzene 7 hours/day, 5 days/ week for 26 consecutive weeks (Coate, Schoenfisch, Busey, and Lewis 1977, as cited in ACGIH 1986/Ex. 1-3, p. 593). Thirty rats, 16 rabbits, and 9 monkeys, all males, were exposed at concentrations of 25, 50, or 100 ppm. Microscopic changes were seen in the parenchymal cells of the livers and kidneys of all rats after weeks 4 and 13 of exposure, but no adverse effects were seen in animals of any other species. In a 90-day gavage study in rats given 1, 10, 100, or 1000 ppm 1,2,4-trichlorobenzene, males in the high-dose groups (100 or 1000 ppm) showed increased liver-tobody weight ratios; at autopsy, significant histopathological changes in the liver, kidney, and thyroid were seen in animals in the highest-dose group (Cote, Chu, Villeneuve, Secous, and Valli 1988, in Drug Chem. Toxicol. 11(1):11-28). 1,2,4-Trichlorobenzene has been shown to have embryotoxic effects in rats by oral administration and reproductive effects in female rats by intraperitoneal administration (RTECS 1990). Another recent study failed to show teratogenicity in the offspring of rats exposed to 150 or 300 ppm 1,2,4trichlorobenzene on days 6 and 15 of gestation (Black, Valli, Ruddick, and Villeneuve 1988, in Bull. Environ. Contam. Toxicol. 41(5):719-726).

In workers, prolonged or repeated skin contact with 1,2,4-trichlorobenzene causes dermal irritation as a result of the defatting action of this chemical (Powers, Coate, and Lewis 1975/Ex. 1-658). In some cases, exposure to concentrations of 3 to 5 ppm caused eye and throat irritation (Rowe 1975, as cited in ACGIH 1986/Ex. 1-3, p. 593). This substance also has been reported to cause liver injury in humans (Gosselin, Smith, and Hodge 1984, p. II-173). One worker who was massively overexposed to trichlorobenzene experienced hemorrhages of the lungs (NRC 1977, p. 774). Exposure to trichlorobenzene has been reported to cause aplastic anemia, leukopenia, and thrombocytopenia in one non-occupational case, and a man whose job required him to fill drums with mono-, orthodi-, and trichlorobenzene developed anemia after 3 years of such exposure (Girard et al. 1969, in J. Med. Lyon 50:771-773).

Based on this evidence, the Agency preliminarily concludes that the PEL being proposed is necessary to protect workers in the construction, maritime, and agriculture sectors from the risk of eye, throat, and dermal irritation and possible liver damage associated with exposure to this substance. OSHA considers these exposure-related effects material impairments of health. To afford workers in these sectors protection from these effects, OSHA is proposing a ceiling limit of 5 ppm for 1,2,4-trichlorobenzene in the construction, maritime, and agriculture industries. Promulgation of this limit will make the PEL for 1,2,4-trichlorobenzene consistent across all OSHA-regulated sectors.

TRIETHYLAMINE
CAS: 121-44-8; Chemical Formula:
(C₂H₆)₃N
H.S. No. 1408

OSHA has an 8-hour TWA limit of 25 ppm for triethylamine in the construction and maritime industries. There is no PEL in agriculture. The ACGIH has a 10 ppm TLV*-TWA and a 15 ppm TLV*-STEL for triethylamine. NIOSH has no REL for this substance. OSHA is proposing an 8-hour TWA limit of 10 ppm and a 15-minute STEL of 15 ppm for this substance in the construction, maritime, and agriculture industries. NIOSH (Ex. 8-47) concurred that these limits were appropriate when OSHA recently established them in general industry.

Triethylamine is a flammable, colorless liquid with a strong ammonia-like odor. Triethylamine is used in the preparation of quaternary ammonium compounds. It is also used as a catalytic solvent in chemical synthesis, as an accelerator activator for rubber, in the curing and hardening of polymers, and as a corrosion inhibitor and propellant

(Hawley's 1987, p. 1180). In addition to sensory irritation, triethylamine causes ocular effects in exposed workers. The oral LD50 in rats is 460 mg/kg, the LCso in mice is 6 g/m3 for 2 hours, and the dermal LD50 in rabbits is 750 mg/kg (RTECS 1990). Guinea pigs exposed for 30 minutes to a triethylamine concentration of 2000 ppm survived, but four of six animals died when exposed to this level for 2 hours; two of six guinea pigs died during a 4hour exposure to a concentration of 1000 ppm, but all survived similar exposures at the 250- and 500-ppm levels (Carpenter, Smyth, and Shaffer 1948/Ex. 1-892). Applied to the skin of rabbits, triethylamine caused mild irritation; instilled into the eyes of rabbits, it caused severe irritation (RTECS 1990). Rabbits exposed repeatedly to a concentration of 50 ppm exhibited marked irritation of the cornea and of pulmonary tissue (Brieger and Hodes

1951/Ex. 1-408; Carpenter and Smyth 1946/Ex. 1-859).

In humans, the effects of repeated triethylamine exposure correspond to those of ethylamine and diethylamine and include irritation of the eyes and mucous membranes and corneal edema and other ocular effects (Brieger and Hodes 1951/Ex. 1–408). Humans exposed to a 12-mg/m³ concentration of triethylamine experienced changes in their visual fields (RTECS 1989). Triethylamine was also found to inhibit monoamine oxidase activity, resulting in central nervous system stimulation (De Bruin 1976/Ex. 1–895).

Based on this evidence in humans and animals, OSHA preliminarily concludes that workers exposed to triethylamine are at significant risk of experiencing sensory irritation and ocular effects, both material impairments of health. Therefore, OSHA is proposing limits for triethylamine of 10 ppm as an 8-hour TWA and 15 ppm as a 15-minute STEL for workplaces in the construction, maritime, and agriculture industries. Promulgation of these PELs will make OSHA's limits for triethylamine consistent across all OSHA-regulated sectors.

TURPENTINE
CAS: 8006-64-2; Chemical Formula:
C₁₀H₆
H.S. No. 2166

In general industry, construction, and maritime, OSHA's permissible exposure limit for turpentine is 100 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 100 ppm for this substance; NIOSH has no REL. OSHA is proposing an 8-hour TWA PEL in agriculture of 100 ppm for turpentine. This is the limit recently established for this substance in general industry.

Turpentine is a volatile mixture of hydrocarbon isomers obtained either from pine gum or pine wood. Gum turpentine is a yellowish, sticky, opaque, combustible material, and the wood distillate (oil of turpentine) is a flammable, colorless liquid with a characteristic odor (Sittig 1985, p. 906; Genium MSDS 1984, No. 375; Hawley's 1987, p. 1200). Turpentine is used as an insecticide, a chemical intermediate, and a flavoring agent. It is also used in the manufacture of cleaning materials, putty, cutting and grinding fluids, and mastics, and as an ingredient in some perfumes, deodorizers, pharmaceuticals, polishes, oils, inks, and stimulating ointments (HSDB 1989). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal

Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Turpentine is an irritant of the eyes, skin, and respiratory tract and causes central nervous system depression in both animals and humans; in humans, exposure also may cause dermal sensitization and gastrointestinal and urinary tract effects. Injection of turpentine into rabbits' eyes produced corneal opacification (Grant 1986, p. 961). The oral LDso in rats is 5760 mg/kg. and the inhalation LCoo for the same species is 12 g/m3 for 6 hours (RTECS 1989). Cats exposed to a concentration of turpentine of between 540 and 720 ppm exhibited signs of eye and respiratory tract irritation and had mild convulsions; at 1440 ppm, they developed paralysis within 150 to 180 minutes (HSDB 1989). Dogs exposed to an 818-ppm concentration of turpentine for 3.5 to 4.5 hours developed nausea, incoordination, mild paralysis, and weakness (Grant 1986, p. 961; Clayton and Clayton 1981, p. 3245); however, no effects were seen in dogs exposed to a 180-ppm concentration for 3.5 hours/day for 8 days (Lehmann and Flury 1943). Turpentine has also caused skin tumors in mice and rats (RTECS 1989; Clayton and Clayton 1981, p. 3245).

The lowest reported oral dose of turpentine that is lethal in humans is 441 mg/kg (RTECS 1989). Exposure to a 75ppm concentration for 3 to 5 minutes irritates the nose and throat, and exposure to 175 ppm irritates the eyes and is considered intolerable (Grant 1986, p. 961; Nelson 1943). Exposure to a turpentine concentration of between 720 and 1100 ppm causes headache, dizziness, nausea, chest pain, and visual disturbances in exposed individuals (Clayton and Clayton 1981, p. 3235). Ingestion of turpentine causes burning pain in the mouth and throat, nausea, vomiting, diarrhea, abdominal pain, excitement, ataxia, confusion, stupor, seizures, fever, and tachycardia and may cause respiratory failure and death (Gosselin, Smith, and Hodge 1984, p. III-394). Repeated or prolonged skin contact causes skin sensitization, with bullous dermatitis and eczema (Clayton and Clayton 1981, p. 3244; Sittig 1985, p. 907). A case-control study of workers demonstrated a statistically significant association between chronic exposure (greater than 5 years) to terpenes (a principal component of turpentine) and the development of respiratory tract cancers (HSDB 1989).

Based on this evidence, OSHA preliminarily concludes that, in the absence of a permissible exposure limit, workers in agriculture are at significant risk of experiencing the eye, skin,

mucous membrane, and respiratory tract irritation and central nervous system depression associated with exposure to turpentine. The Agency believes these effects are material impairments of health and that establishing an 8-hour TWA PEL of 100 ppm in agriculture is necessary to substantially reduce these risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

VANADIUM PENTOXIDE DUST, RESPIRABLE CAS: 1314-62-1; Chemical Formula: V_2O_5

H.S. No. 1421

The OSHA PEL for vanadium pentoxide (V₂O₅) dust in the construction and maritime industries is a ceiling of 0.5 mg/m³. There is no PEL in agriculture. The ACGIH has an 8-hour TLV*-TWA of 0.05 mg/m³ for vanadium pentoxide dust, and NIOSH has a 15-minute ceiling of 0.05 mg/m³ for this substance. The Agency is proposing a 0.05 mg/m³ 8-hour TWA limit for vanadium pentoxide dust in the construction, maritime, and agriculture industries. This is the limit recently established for this dust in general industry.

Vanadium pentoxide is a yellow to rust-brown crystalline compound; the powdered material is used as a catalyst in the preparation of vanadium alloys and compounds, as an oxidation catalyst, as a component of ferrovanadium steels, and in the manufacture of pigments and glazes. Vanadium pentoxide dust is also used as a catalyst in the textile industry, in the manufacture of UV filter glass, in photographic developers, and in the cleaning and maintenance of furnaces (NIOSH/OSHA Occupational Health

Guideline 1981, p. 3).

In addition to sensory irritation, exposure to vanadium dust causes central nervous system effects in experimental animals. Because the literature often fails to distinguish between the dust and the fume, much of the following material may apply to one or both forms. Exposure to a concentration of 205 mg/m3 for 7 hours was lethal to rabbits; animals exhibited signs of pulmonary edema before death (HSDB 1985). The oral LD50 in rats is 10 mg/kg, and the lowest lethal concentration in the same species is 70 mg/m3 for 2 hours (RTECS 1990). Animals acutely poisoned by oral administration developed marked diarrhea, an exudate from the nose, hind limb paralysis, difficult breathing, and convulsions (Gosselin, Smith, and Hodge 1984, p. II-148). Dogs, rats, guinea

pigs, and rabbits exposed to V₂O₅ (at a V/m³ concentration of 0.5 mg/m³) 6 hours/day for 6 months showed no exposure-related histopathological effects at autopsy (Clayton and Clayton 1981, p. 2021). Another study that exposed rabbits to unspecified concentrations of vanadium pentoxide dust for 8 months showed no fibrotic changes in the lungs of these animals.

Several studies indicate that OSHA's current exposure limit is not sufficient to protect workers in construction and maritime against vanadium pentoxide dust's respiratory effects, which include bronchitis, emphysema, tracheitis. pulmonary edema, and bronchial pneumonia. Seven cases of upper respiratory tract irritation were reported in boiler cleaners exposed to vanadium pentoxide concentrations ranging from 2 to 85 mg/m3 (Sjôberg 1951/Ex. 1-437). Williams (1952/Ex. 1-456) reported eight cases of vanadium poisoning in workers cleaning boilers in an atmosphere ranging from 30 to 104 mg/m3. Gul'ko (1956, as cited by Hudson 1964/Ex. 1-880) observed eye and bronchial irritation in workers exposed to concentrations between 0.5 and 2.2 mg/ m3. A study by Lewis (1959/Ex. 1-345) indicated that workers exposed to vanadium pentoxide levels of 0.2 to 0.5 mg/m3 experienced a higher incidence of respiratory symptoms than did controls. Tebrock and Machle (1968/Ex. 1-446) reported that workers exposed to average concentrations of 1.5 mg/m3 vanadium pentoxide in a mixed dust developed conjunctivitis, tracheobronchitis, and dermatitis. A single 8-hour exposure to an average concentration of 0.2 mg/m3 (respirable vanadium pentoxide dust) caused severe upper respiratory tract irritation in five human volunteers, and two other subjects exposed to a 0.1-mg/m3 concentration also developed delayed cough and an increase in mucus production (Zenz and Berg 1967/Ex. 1-405). Frequent cases of asthma have been reported among workers exposed to vanadium pentoxide dust, which suggests that asthma may be a result of chronic exposure (NIOSH Criteria 1977). A recent study (Huang 1989) reports that 76 Chinese workers exposed to vanadium pentoxide fume at a concentration of 1.2 to 18 mg/m3 and to the dust at concentrations ranging from 1.27 to 27 mg/m3 had lung markings on their chest roentgenograms and reported the following signs and symptoms: Cough (63 workers), cough and expectoration (53 workers), difficult breathing (27 cases), wheezing and rales (31 cases). Fifteen of these workers

showed evidence of pulmonary fibrosis

on their roentgenograms.

In the construction, maritime, and agriculture industries, OSHA is proposing a limit of 0.05 mg/m3 as an 8hour TWA for respirable vanadium dust, measured as vanadium pentoxide. The Agency preliminarily concludes that this limit will prevent or substantially reduce the significant risks of eye and bronchial irritation, respiratory symptoms, conjunctivitis, and coughing seen in workers exposed to this substance at concentrations ranging from 0.1 to 2.2 mg/m3. OSHA considers these exposure-related effects material impairments of health. Promulgation of the new PEL will also make OSHA's limit for this substance consistent across all OSHA-regulated sectors.

VANADIUM PENTOXIDE FUME CAS: 1314-62-1; Chemical Formula: V₂O₅

V₂O₅ H.S. No. 1422

OSHA's PEL for vanadium pentoxide (V₂O₈) fume in the construction and maritime industries is 0.1 mg/m³ as a ceiling limit. There is no PEL in agriculture. The ACGIH has an 8-hour TLV*-TWA of 0.05 mg/m³ for vanadium pentoxide fume, and NIOSH has a 0.05 mg/m³ 15-minute ceiling for this substance. OSHA is proposing an 8-hour TWA of 0.05 mg/m³ for vanadium pentoxide fume in the construction, maritime, and agriculture industries. This is the limit recently established for the fume in general industry.

Vanadium pentoxide is a yellow to rust-brown noncombustible crystalline compound; its fume appears as finely divided particulate dispersed in air.

Vanadium pentoxide fume may be generated when vanadium pentoxide is used in the production of pellets from electric furnaces, in metallurgical processes in furnaces, in the manufacture of semiconductors fused with sodium oxide, in welding, and in the fabrication of alloys for use as an additive in special steels (NIOSH/OSHA Occupational Health Guideline

In addition to sensory irritation, exposure to vanadium fume causes central nervous system effects in humans and experimental animals. In humans, overexposure to the fume causes metal fume fever. Because the toxicology literature often fails to distinguish between the dust and the fume, much of the following material may apply to one or both forms. There are no acute toxicity data specifically for the fume.

Vanadium pentoxide fume's chief toxic effects in humans are manifested in the respiratory passages: bronchitis, emphysema, tracheitis, pulmonary edema, and bronchial pneumonia can result from exposure. Seven cases of upper respiratory tract irritation were reported in boiler cleaners exposed to vanadium pentoxide concentrations ranging from 2 to 85 mg/m³ (Sjôberg 1951/Ex. 1-437). Williams (1952/Ex. 1-456) reported eight cases of vanadium poisoning in workers cleaning boilers in an atmosphere ranging from 30 to 104 mg/m3. Gul'ko (1956, as cited by Hudson 1964/Ex. 1-880) observed eye and bronchial irritation in workers exposed to concentrations of 0.5 to 2.2 mg/m3. A study by Lewis (1959/Ex. 1-345) indicated that workers exposed to concentrations of 0.2 to 0.5 mg/m3 experienced a higher incidence of respiratory symptoms than did controls. Tebrock and Machle (1968/Ex. 1-446) reported that workers exposed to average concentrations of 1.5 mg/m3 vanadium pentoxide in a mixed dust/ fume atmosphere developed conjunctivitis, tracheobronchitis, and dermatitis. A single 8-hour exposure to an average concentration of 0.2 mg/m3 (respirable vanadium dust) caused severe upper respiratory tract irritation in five human volunteers, and two other subjects exposed to a 0.1-mg/m3 concentration also developed delayed cough and an increase in mucus production (Zenz and Berg 1967/Ex. 1-405). Frequent cases of asthma have been reported among workers exposed to vanadium pentoxide, which suggests that asthma may be a result of chronic exposure (NIOSH Criteria 1977). A recent study (Huang 1989) reports that 76 Chinese workers exposed to vanadium pentoxide fume at a concentration of 1.2 to 18 mg/m3 and to the dust at concentrations ranging from 1.27 to 27 mg/m3 had lung markings on their chest roentgenograms and reported the following signs and symptoms: cough (63 workers), cough and expectoration (53 workers), difficult breathing (27 cases), wheezing and rales (31 cases). Fifteen of these workers showed evidence of pulmonary fibrosis on their roentgenograms.

Based on this evidence in humans and animals, the Agency preliminarily concludes that the proposed TWA limit is necessary to protect workers in construction, maritime, and agriculture from the significant risks of eye, skin, and upper respiratory tract irritation; conjunctivitis; pulmonary damage; and systemic poisoning associated with exposure to vanadium pentoxide fume. The Agency considers these exposure-related effects to be material impairments of health. Accordingly, OSHA is proposing a PEL of 0.05 mg/m³ as an 8-hour TWA for this substance in

these sectors. Promulgation of this limit will also make the PEL for the fume consistent across all OSHA-regulated sectors.

VINYL ACETATE
CAS: 108-05-4; Chemical Formula:
CH₃COOCH = CH₂
H.S. No. 1424

There is no OSHA limit for vinyl acetate in the construction, maritime, or agriculture industries. The ACGIH has an 8-hour TLV®-TWA limit of 10 ppm and a 20 ppm TLV®-STEL for vinyl acetate. NIOSH has a 15-minute ceiling limit of 4 ppm for this substance. OSHA is proposing to establish a 10-ppm 8-hour TWA and a 20-ppm 15-minute STEL for this substance in construction, maritime, and agriculture. These are the limits recently established for this substance in general industry.

Vinyl acetate is a volatile liquid that polymerizes in light to a colorless, transparent mass; in industry, this substance usually contains an inhibitor, such as hydroquinone. Vinyl acetate is used for the manufacture of polyvinyl resins and in latex paints, paper coatings, adhesives, textile finishes, and safety glass interlayers (Hawley's 1987, p. 1222).

Vinyl acetate causes irritation of the eyes, nose, and throat. The oral LD50 in rats is 2920 mg/kg, the LC50 in rabbits is 2500 ppm for 4 hours, and the dermal LD50 in rabbits is 2335 mg/kg (RTECS 1990). Instilled into rabbit eyes, vinyl acetate caused mild irritation; in contact with the skin, this substance also caused irritation (RTECS 1990). Some beagle dogs exposed to a 240-ppm concentration of vinyl acetate for 4 hours showed signs of eye irritation (Mellon Institute 1968). Rats exposed repeatedly to a vinyl acetate concentration of 100 ppm showed no adverse effects (Proctor, Hughes, and Fischman 1988, p. 504). Rats and mice inhaling 13.2 or 68 mg/m3 vinyl acetate continuously for 4 months showed a dose-related pulmonary response; findings included emphysema and lung atelectases, as well as effects on the central nervous system, adrenal glands, and hypophysis (HSDB 1989). In mice. vinyl acetate caused a dose-dependent decrease in sperm production and a reduction in testicular weight when the animals were exposed to this substance at a dose of 125 mg/kg/day (Lahdetie 1988). In one oral carcinogenicity bioassay, rats given 100 g/kg vinyl acetate for 2 years developed uterine and thyroid tumors (RTECS 1990); however, another cancer bioassay (Maltoni 1976) was negative (cited in

Proctor, Hughes, and Fischman 1988, p.

The basis for the proposed limits is an epidemiologic report by Deese and Joyner (1969/Ex. 1-412) describing 15 years of industrial experience with vinyl acetate production. These authors reported that vinyl acetate is not a significant irritant at exposure concentrations of 5 to 10 ppm but that it causes cough and hoarseness around 22 ppm. They also found no evidence of adverse chronic effects resulting from exposure to concentrations of 5 to 10 ppm, as determined from medical records and examinations of workers exposed to these levels. While conducting air sampling for the study, the primary author (Deese) experienced hoarseness at vinyl chloride concentrations of 4.2 to 5.7 ppm, and eye irritation at 5.7 to 6.8 ppm. Three chemical operators and one technician involved in this study did not report any subjective responses at these levels. Severe skin irritation or blistering may occur in workers whose skin is in contact with vinyl acetate (NIOSH Criteria Document 1978). One worker whose eye was burned by a splash of vinyl acetate recovered fully within 48 hours (Grant 1986, p. 978). Changes in pulmonary function were observed in persons employed in the production of vinyl acetate (HSDB 1987).

Based on this evidence in humans and animals, OSHA preliminarily concludes that exposure to this substance causes eye, throat, and skin irritation and possible changes in pulmonary function. The Agency considers these effects material impairments of health and believes that the proposed PELs will substantially reduce the risk that workers in construction, maritime, and agriculture will experience these effects. Promulgation of these limits will also make the PELs for vinyl acetate consistent across all OSHA-regulated

sectors.

VINYL TOLUENE CAS: 25013-15-4; Chemical Formula: CH3C6H4CH=CH2 H.S. No. 1427

OSHA's PEL for vinyl toluene in construction and maritime is an 8-hour TWA of 100 ppm. There is no PEL in agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. The ACGIH has a TLV*-TWA of 50 ppm and a 100-ppm TLV*-STEL for vinyl toluene. OSHA is proposing an 8-hour TWA PEL for this substance of 100 ppm in agriculture. This is the limit recently established for this substance in general industry.

Vinyl toluene is a colorless liquid with a strong, disagreeable odor that finds

use as a solvent, in resin production, in the plastics industry, and as a component of insecticides (ACGIH 1986, p. 630; Clayton and Clayton 1981, p. 3319). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Wolf, Rowe, McCollister et al. (1956/ Ex. 1-404) noted fatty degeneration of the liver and an increase in kidney and liver weights in rats, guinea pigs, rabbits, and monkeys subjected to approximately 100 7- to 8-hour exposures to vinyl toluene at a concentration of 1250 ppm. Some deaths occurred among the rats in this group. Animals exposed to vinyl toluene at a 600-ppm concentration appeared normal and showed no blood or urine abnormalities, no gross or microscopic tissue changes, and no changes in growth rate or organ weight (Wolf, Rowe, McCollister et al. 1956/Ex. 1-404). When vinyl toluene was dropped into the eyes of rabbits, it caused conjunctival irritation; in contact with rabbit skin, it caused reversible necrosis and edema (Proctor, Hughes, and Fischman 1988, p. 507). By intraperitoneal administration, vinyl toluene is fetotoxic in rats (RTECS 1989).

Human volunteers reported experiencing eye and nose irritation at a 400-ppm concentration and objectionable odor at a concentration of 300 ppm. At 50 ppm, the odor of vinyl toluene was detectable by volunteers, but these individuals experienced no irritation and did not find the odor intolerable (ACGIH 1986/Ex. 1-3, p.

OSHA is proposing an 8-hour TWA limit of 100 ppm in agriculture. The Agency preliminarily concludes that the proposed limit is necessary to protect workers in this sector against the significant risk of intolerable odor and irritation caused by vinyl toluene exposures in the workplace. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. VM & P NAPHTHA

CAS No. 8032-32-4; Chemical Formula: none

H.S. No. 1429

OSHA has no PEL for VM & P (Varnish Makers' and Printers') naphtha in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 300 ppm for VM & P naphtha, and NIOSH has no REL for this substance. OSHA is proposing a 300-ppm 8-hour TWA and a 400-ppm STEL for VM & P naphtha in the construction, maritime, and

agriculture sectors. NIOSH concurred (Ex. 8-47) that these limits were appropriate when the Agency recently established them in general industry.

VM & P naphtha, also known as ligroin, is a colorless, flammable liquid that has an aromatic odor. VM & P naphtha is used as a diluent for paints, coatings, resins, printing inks, and rubber cement and as a solvent (ACGIH

1986, p. 631).

In addition to sensory irritation, VM & P naphtha causes central nervous system depression in humans and animals. The LC50 in rats is 3400 ppm for 4 hours (RTECS 1990). Rats lost coordination and convulsed after being exposed for 15 minutes at room temperature to a saturation concentration of this substance (Carpenter 1975). Temporary hematologic effects were observed in rats and dogs exposed to a concentration of 1200 ppm for 40 days (Clayton and Clayton 1981, p. 3389). A study in which rats and beagles received inhalation doses of 500 ppm VM & P naphtha for 30 hours per week for 13 weeks resulted in no chronic or latent effects (Carpenter, Kinkead, Geary et al. 1975a/Ex. 1-302). These authors also noted that the acute toxicity of VM & P naphtha for rats and other species was four times greater than that of rubber solvent naphtha, which has a limit of 400 ppm.

Seven human volunteers exposed to a VM & P naphtha concentration of 880 ppm for 15 minutes reported upper respiratory tract, eye, and nose irritation, in addition to olfactory fatigue (ACGIH 1986/Ex. 1-3, p. 631). Elkins (1959d, as cited in ACGIH 1986/Ex. 1-3, p. 631) noted one case of a worker, exposed to levels of VM & P naphtha averaging 800 ppm, who developed unspecified chronic effects. Elkins also reported that the VM & P naphtha level producing significant irritation in human volunteers was about half as great for this form of naphtha as for rubber solvent naphtha. An accidental exposure of 19 workers to an unspecified concentration of this substance caused dyspnea; two of these workers developed cyanosis and tremor (Wilson 1976).

The Agency preliminarily concludes that a 300-ppm 8-hour TWA PEL and a 400-ppm 15-minute STEL are necessary to protect workers in construction, maritime, and agriculture from irritation and central nervous system effects associated with naphtha exposure. OSHA considers these effects material impairments of health and is therefore proposing both a 300-ppm 8-hour TWA and a 400-ppm 15-minute STEL for VM & P naphtha in the construction, maritime, and agriculture sectors. Promulgation of these limits will make the PELs for VM & P naphtha consistent across all OSHA-regulated sectors.

XYLENES, (o-, m-, and p-ISOMERS)
CAS: 1330-20-7; Chemical Formula:
C6H4(CHs)2
H.S. No. 1431

The OSHA limit for the xylenes is 100 ppm as an 8-hour TWA in the construction and maritime industries. There is no PEL in agriculture. The ACGIH has an 8-hour TLV*-TWA of 100 ppm and a TLV*-STEL of 150 ppm for xylene. NIOSH has a recommended exposure limit of 100 ppm as a TWA and a 10-minute ceiling limit of 200 ppm for this substance. OSHA is proposing a 100 ppm TWA and 150 ppm STEL for xylene in the construction, maritime, and agriculture industries. NIOSH (Ex. 8-47) concurred with these limits when they were established recently in general industry.

The xylene isomers are clear, flammable liquids that have an aromatic hydrocarbon odor. Xylene is present in gasoline and in many petroleum solvents. Xylene is used to make insecticides, drugs, and dyes, as a solvent in paints and other coatings (especially alkyl resins), and in rubber cements (ACGIH 1986, p. 637).

In addition to sensory irritation, xylene causes narcosis in humans and animals at high concentrations. The 4hour LC50 in rats is 5000 ppm and the oral LDso in the same species is 4300 mg/ kg (RTECS 1990). In contact with the skin of rabbits, 500 mg caused moderate skin irritation; instilled into rabbit eyes, this substance caused mild eye irritation. Rats exposed to a concentration of 1600 ppm for 2 or 4 days showed signs of mucous membrane irritation, became incoordinated, lost weight, and had an increased erythrocyte count (NIOSH Criteria Document 1975). Rats were exposed orally to p-xylene at 125, 250, 500, 1000, or 2000 mg/kg or to 800 or 1600 ppm xylene for 4 hours. Rats exposed to doses above 250 mg/kg or to 1600 ppm showed a significant depression in flash evoked potentials (FEPs) (FEP is an index of the functional integrity of the visual system) (Dyer, Bercegeay, and Mayo 1968, Neurotoxicol. Teratol. 10(2):147-153). Leukopenia, kidney congestion, and hyperplasia of the bone and spleen were seen in rats exposed to 980 ppm for 7 days. Some mice died after being exposed to 2010 ppm mxylene or o-xylene for 24 hours; however, those exposed to 4912 ppm pxylene survived (NIOSH Criteria Document 1975). Rats and rabbits

exposed to a mixture of xylene isomers at a concentration of 690 ppm for eight hours daily, six days per week showed no blood abnormalities, but rabbits exposed on the same regimen at 1150 ppm for 55 days showed a decrease in red and white blood cell counts and an increase in platelet count (Fabre and Truhaut 1954, as cited in ACGIH 1986/ Ex. 1-3, p. 637). Sprague-Dawley rats were given 250, 1000, or 2000 mg/kg mxylene, o-xylene, or p-xylene by gavage for 10 days, or 150, 750, or 1000 mg/kg mixed xylene isomers by gavage for 90 days. Males in the highest dose group of the 10-day study had significantly reduced body weights and significantly increased relative liver weights (all isomers). In the 90-day study, rats of both sexes had dose-related increases in relative liver and kidney weights (Condie, Hill, and Borzelleca 1988, Drug Chem. Toxicol. 11(4):329-354). Teratogenicity studies in rats, hamsters, rabbits, and mice administered xylene by two routes of exposure (inhalation and oral) have shown that this substance causes developmental abnormalities and is fetotoxic (RTECS

1990; HSDB 1989).

Studies of workers exposed to xylene revealed headache, fatigue, lassitude, irritability, and gastrointestinal disturbances as the most common symptoms (Gerarde 1960d/Ex. 1-738a). At unspecified exposure levels, Browning (1965b/Ex. 1-1016) also noted gastrointestinal disturbances, in addition to kidney, heart, liver, and neurological damage; blood dyscrasias, some of which resulted in death, were also reported in these workers. A study by Nelson, Enge, Ross, et al. (1943/Ex. 1-66), in which human volunteers were exposed to 200 ppm xylene, found eye, nose, and throat irritation in the subjects at this level of exposure. Volunteers exposed for 3 hours 40 minutes to mxylene either at 200 ppm or at 135 ppm combined with two 20-minute 400 ppm peak exposures per day showed changes in their visual evoked potentials during exercise; these changes suggest that exposure to m-xylene activated these subjects' arousal levels (Sappalainen, Laine, Salmi, Riihimaki, and Verkkala 1989, in Int. Arch. Occup. Environ. Health 61(7):443-449). Morley, Eccleston, Douglas, and colleagues (1970/Ex. 1-794) observed liver dysfunction and renal impairment in three workers overexposed to xylene (estimated concentration of 10,000 ppm). One of these workers died, but the others recovered slowly. Furniture polishers were reported by Matthaus (1984/Ex. 1-830) to have suffered corneal damage as a result of exposure to xylene at unknown concentrations. A workman

was exposed to nearly pure xylene for 3 years during boat hull repair (estimated exposure = several hundred ppm). He developed the following signs and symptoms of acute organic brain syndrome: dysphasia, fine tremor, agitation, breathlessness, fatigue, impaired concentration and short-term memory, and confusion, hyperreflexia, and unstable gait. The worker recovered over the next 2 years after exposure was terminated (Roberts, Lucas, Marsden, and Traner 1988, in Lancet II (8605):273).

Based on this evidence, OSHA preliminarily concludes that both a TWA and a STEL are necessary to prevent the risks of narcosis, blood effects, and irritant effects among workers exposed to xylene in the construction, maritime, and agriculture industries. The Agency considers these exposure-related effects to be material impairments of health. Therefore, to reduce these occupational risks among workers exposed to xylene, OSHA is proposing a 100-ppm TWA and a 150ppm STEL for this substance in the construction, maritime, and agricultural industries. Promulgation of these limits will make OSHA's PELs for xylene consistent across all OSHA-regulated sectors.

ZINC CHLORIDE (FUME)
CAS: 7648-85-7; Chemical Formula:
ZnCl₂
H.S. No. 1435

OSHA's limit for zinc chloride fume in the construction and maritime industries is 1 mg/m³ as an 8-hour TWA. There is no PEL in agriculture. The ACGIH has an 8-hour TLV*-TWA of 1 mg/m³ and a TLV*-STEL of 2 mg/m³ for zinc chloride fume. NIOSH has no REL for this substance. OSHA is proposing an 8-hour TWA of 1 mg/m³ and a STEL of 2 mg/m³ for zinc chloride fume. NIOSH (Ex. 8-47) concurred that these limits were appropriate when OSHA recently established them in general industry.

Zinc chloride fume is white and has an acrid odor. Zinc chloride is used in soldering fluxes, to galvanize iron, as a wood preservative, in the textile industry, as an ingredient in adhesives, dentifrices, deodorants, and embalming fluids, and in organic synthesis and petroleum refining. It is also the main ingredient of some screening smokes (ACGIH 1986, p. 643).

Zinc chloride fume causes sensory irritation in humans and animals at high concentrations. The oral LD₅₀ in rats is 350 mg/kg, and the lowest lethal concentration in the same species is 1960 mg/m³ for 10 minutes (RTECS 1990).

In humans, zinc chloride fume is highly caustic and damages the mucous membranes of the nasopharynx and respiratory tract. Exposure to the fumes of zinc chloride may result in a severe pneumonitis that is caused by irritation of the respiratory tract (Gafafer 1964/Ex. 1-1149). There are two reports of solderers who developed occupational asthma (confirmed by positive bronchial challenge) after soldering with soft corrosive soldering fluxes that contained both zinc chloride and ammonium chloride (Weir, Robertson, Jones, and Burge 1989, in Thorax 44(3):220-223). One instance in which a worker inhaled zinc chloride fumes resulted in advanced pulmonary fibrosis that ended in death (Milliken, Waugh, and Kadish 1963/Ex. 1-751), and 10 deaths and 25 nonfatal cases of pneumonitis occurred in workers caught in a tunnel when 79 smoke generators caught fire and generated zinc chloride fumes (Hunter 1955/Ex. 1-853). A firefighter exposed to a high concentration of zinc chloride fume experienced nausea, sore throat, and chest tightness. After some improvement in health, this worker developed tachypnea, substernal soreness, fever, cyanosis, and coma prior to death 18 days after initial exposure (Melliken, Waugh, and Kadish 1963). A recent NIOSH study (Zey and Richardson 1985) reports that the zinc chloride fumes generated by smokegenerating devices reach concentrations of between 11 to 498 mg/m3 and that firefighters have experienced severe adverse effects, including death, from such exposures (in NIOSH HETA 85-274-1979, 1985). Five Danish military workers were acutely overexposed to zinc chloride smoke during military training; two of these men breathed zinc chloride at an unspecified concentration for 1 to 2 minutes and subsequently developed severe adult respiratory distress syndrome (ARDS). Both patients died; autopsy revealed microvascular obliteration, widespread occlusion of the pulmonary arteries, and extensive interstitial and intra-alveolar fibrosis (Hjortso, Qvist, Bud, Thomsen, Andersen, et al. 1988, in Inten. Care

Med. 14(1):17–24). Other studies have shown that long-term zinc chloride exposures cause skin ulceration (Sax 1957/Ex. 1–1095). It has also been suggested that zinc chloride exposure may have chronic effects (Hamilton and Hardy 1974b/Ex. 1–958). In an investigation of the adverse effects of zinc chloride fume exposures, Ferry (1966, as cited in ACGIH 1986/Ex. 1–3, p. 643) reported that no sensory effects occurred when 30-minute exposures were limited to 0.07 and 0.4 mg/m³; however, this researcher noted that these levels did corrode metal.

Based on this evidence, OSHA preliminarily concludes that exposure to this substance is associated with a significant risk of damage to the eyes, skin, and respiratory tract and of pneumonitis, all of which are considered by OSHA to be material impairments of health. The Agency believes that the proposed PELs will substantially reduce these risks. Accordingly, OSHA is proposing a 1 mg/m3 TWA limit and 2 mg/m3 STEL for this substance in the construction, maritime, and agriculture industries. Promulgation of these limits will make the PELs for zinc chloride fume consistent across all OSHAregulated sectors.

Preliminary Conclusions for the Group of Sensory Irritants

OSHA preliminarily finds that sensory irritation poses an occupational health risk to workers in the construction, maritime, and agricultural sectors who are exposed to these substances in their places of work. Among the adverse health consequences of exposure to sensory irritants are acute breathing difficulty, lacrimation, conjunctivitis, sensitization, persistent coughing, and upper respiratory tract irritation. OSHA has preliminarily determined that these effects constitute material impairments of health and functional capacity within the meaning of the Act. In addition to the pain and suffering associated with these signs and symptoms, workers experiencing irritant effects find it difficult if not impossible to concentrate on the job at hand; they therefore work less safely and less productively than

nonexposed employees. Reducing exposures from levels that have been associated with these effects to levels where such consequences are substantially less likely to occur will substantially reduce the significant risk posed to workers at current levels. Furthermore, many of the substances in this group have been demonstrated to have adverse effects on other organ systems, including the cornea, lungs, kidney, liver, central nervous system, and gastrointestinal tract. In addition, promulgation of the proposed limits in construction, maritime, and agriculture will make the Agency's limits for these contaminants consistent across all OSHA-regulated industries.

4. Substances for Which Proposed Limits Are Based on the Avoidance of Liver or Kidney Effects

Introduction

Two of the target organs most often affected by toxic exposure to industrial chemicals are the liver and the kidney. In recognition of this target organ toxicity, OSHA is establishing new or revised limits for 34 hepato- or nephrotoxic compounds. For these substances, the liver or kidney appears to be the organ most sensitive to the effects of exposure. Thus, establishing permissible exposure limits that are low enough to prevent toxicity to these target organs often also protects other organ systems.

Table C4-1 lists these hepatotoxic substances, along with their CAS numbers, H.S. numbers, 1987-1988 ACGIH TLV*s, and NIOSH RELs. In addition, Table C4-1 shows OSHA's current PELs for these substances in construction and maritime. Table C4-2 provides the same information for the nephrotoxins addressed in this section of the proposal. OSHA has no PELs for these substances in agriculture. Both on Tables C4-1 and C4-2, the right-hand column shows the limits OSHA is proposing today for construction, maritime, and agricultural workplaces. These limits are identical to those recently promulgated in general industry.

1407 1,2,3-Trichloropropane	96-18-4	50 ppm TWA	. 10 ppm TWA, Skin		10 ppm TWA

*OSHA's TWA limits are for 8-hour exposures; its STELs are for 15 minutes only unless otherwise specified; and its ceilings are peaks not to be exceeded for any period of time; OSHA's PELs do not currently apply in Agriculture.

*The ACGIH TLV *-TWA is for an 8-hour exposure; its STELs are 15-minute limits not to be exceeded more than 4 times per day with a minimum of 60 minutes between successive STEL exposures; and its ceilings are peaks not to be exceeded for any period of time. An A2 designation means that the ACGIH classifies the substance as a suspected human carcinogen.

†NIOSH TWA limits are for 10 hour/day, 40 hour/week exposures unless otherwise specified, and its ceilings are peaks not to be exceeded for any period of time unless a duration is specified in parentheses.

†NIOSH considers this substance a potential occupational carcinogen and recommends that exposures be reduced to the lowest feasible concentration.

Description of the Health Effects

The precise mechanisms by which toxic substances cause liver damage are not fully understood. In general, however, liver toxicity is a graded response (i.e., the severity of the lesion is directly proportional to the intensity/ duration of exposure). Although many of the effects caused by exposure to these substances are reversible, some are not.

Liver damage is not a single entity; the manner in which it is manifested depends on the dose, duration, and particular chemical agent involved. For example, acute exposures may cause lipid accumulation in liver cells, cell death, and hepatobiliary dysfunction. In contrast, chronic overexposure leads to

cirrhotic changes and the development of neoplasms. Fatty accumulation and necrosis can be either localized or widespread, and chemically induced lesions resulting from chronic exposures can cause marked changes of the entire liver (Plaa 1986/Ex. 1-183).

Typically, the earliest and most sensitive indicators of liver toxicity are alterations in biochemical liver functions, such as changes in specific enzyme activities. These may be accompanied by changes in the morphology of specific organelles in hepatocytes. For example, relatively low doses of halogenated aliphatic hydrocarbons, such as allyl chloride, carbon tetrabromide, and ethylene dichloride, cause an increase in the

activity of microsomal mixed-function oxidase enzymes. This increase is ordinarily accompanied by proliferation of the endoplasmic reticulum.

Many compounds that damage the liver, such as 1,1,2,2-tetrachloroethane, also cause an abnormal accumulation of fat, especially of triglycerides, in liver cells. In experimental animals, this effect is manifested as an accumulation of microscopic vacuoles in liver cells. In humans, however, the only grossly detectable manifestation of this effect is increased liver size, which is an indication of severe fat accumulation in the liver.

At sufficiently high doses, most substances that damage the liver cause cell death that leads to tissue necrosis or gangrene. This necrosis may initially be localized, but, at higher or more sustained exposure levels, the entire liver may be involved. Moderate to severe liver necrosis is usually accompanied by increased concentrations of marker enzymes such as glutamate-pyruvate transaminase or glutamate-oxaloacetate transaminase in the serum; the detection of these substances in the serum of exposed individuals can thus be a useful diagnostic tool.

Dose-Response Characteristics

The development of liver and other organ damage in humans and animals is progressive; it begins with subcellular changes, progresses to the cellular level, and is finally manifested as whole-organ damage. This progression is related to the intensity/duration of dose (i.e., as dose increases, cellular death becomes widespread and eventually causes liver dysfunction). The extent to which liver damage is reversible follows a similar continuum; since the liver can regenerate, minor cellular damage or transient disease states are usually reversible if exposure ceases. However, if exposure continues, the capacity of the liver to regenerate is exceeded and permanent damage results. As is the case for some chemically induced toxic effects, there appears to be a noobserved-effect level below which hepatotoxic effects do not occur.

The following paragraphs describe OSHA's preliminary findings for all of the substances in this group of hepatotoxins. Each discussion reports on the principal acute and chronic health effects associated with exposure to the substance and describes the physical properties and uses of the substance.

ACETYLENE TETRABROMIDE CAS: 79-27-6; Chemical Formula: CHBr₂CHBr₂ H.S. No. 2001

In general industry, construction, and maritime, OSHA's current permissible exposure limit for acetylene tetrabromide is 1 ppm as an 8-hour TWA; there is no limit in agriculture. The ACGIH TLV*-TWA for acetylene tetrabromide is 1 ppm (14 mg/m³); there is no NIOSH REL for this substance. OSHA is proposing an 8-hour TWA PEL of 1 ppm for acetylene tetrabromide in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all regulated sectors.

Acetylene tetrabromide is a pale yellow, dense, non-combustible liquid with a sweet, chloroform-like odor (ACGIH 1986, p. 9; Genium MSDS 1985, No. 562). This substance is used as a

solvent for fats, oils, and waxes; as a gauge fluid; as a catalytic polymer additive in synthetic fibers such as flame-resistant polystyrenes, polyurethanes, and polyolefins; as a refractive index liquid in microscopy; and as an ore flotation agent (Proctor, Hughes, and Fischman 1988, p. 54; Hawley's 1987, p. 11; HSDB 1986).

Acetylene tetrabromide is a sensory irritant, a liver toxin, and a central nervous system depressant. The LCso in rats is 549 mg/m3 for 4 hours, and the oral LDso in the same species is 1100 mg/ kg (RTECS 1990). The dermal LD50 in rats is 5250 mg/kg (RTECS 1990). Guinea pigs exposed to a concentration of approximately 80 ppm acetylene tetrabromide for 90 minutes initially became comatose, appeared to recover, and then died after several days; rats and rabbits exposed to the same concentration for 3 hours lost consciousness after 2 hours but survived (Gray 1950). In another study, rats exposed to a concentration of approximately 80 ppm for 7 hours showed signs of slight eye and nose irritation (Hollingsworth, Rowe, and Oyen 1963). Rats exposed to aerosols of acetylene tetrabromide at concentrations ranging from 210 to 280 ppm for 2 hours showed mild signs of toxicity, and exposure to concentrations of from 420 to 500 ppm caused excitation followed by sleepiness (Arkhangel-Skaya and Yanushkevich 1956). Liquid acetylene tetrabromide instilled into the eyes of rabbits caused slight-tomoderate pain, conjunctival irritation, and reversible corneal injury (Van Haaften 1969). In prolonged contact with the skin of experimental animals, acetylene tetrabromide causes moderate redness, edema, and blistering (Van Haaften 1969; Clayton and Clayton 1981,

Rats, rabbits, mice, and a monkey exposed to a 14-ppm concentration of acetylene tetrabromide for 7 hours/day for 100 days showed edema of the lungs and slight fatty degeneration of the liver at autopsy; repeated exposure to a 4ppm concentration for 180 days caused slight histopathological changes in the liver and lungs of some animals. At a 1ppm concentration, no exposure-related effects were seen (Hollingsworth, Rowe, and Oyen 1969). A skin painting study in mice showed an increased incidence of lung tumors and/or forestomach papillomas in the test animals (Van Duuren et al., 1979).

A chemist exposed to an estimated average acetylene tetrabromide concentration of 2 ppm for 7.5 hours, with a peak exposure of 16 ppm for 10 minutes, complained of headache, anorexia, and nausea within a few hours

of exposure. Within 5 days, he developed abdominal pain, bilirubinuria, and monocytosis; he also experienced liver damage that was severe and nearly fatal (Van Haaften 1969).

Based on this evidence in humans and animals, OSHA proposes to establish an 8-hour TWA PEL for acetylene tetrabromide of 1 ppm in agriculture; adoption of the proposed limit would establish the same PEL for workplaces in all OSHA-regulated industry sectors. The Agency preliminarily concludes that occupational exposure to acetylene tetrabromide causes sensory irritation and may cause liver damage and central nervous system depression. OSHA believes that, in the absence of a permissible exposure limit, workers in agriculture are potentially at significant risk for these exposure-related effects and that the proposed PEL will substantially reduce these risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

ALDRIN

CAS: 309–00–2; Chemical Formula: C₁₂H₈Cl₆ H.S. No. 2003

OSHA currently has no PEL for aldrin in agriculture; the limit for this substance in general industry, construction, and maritime is 0.25 mg/ m3 as an 8-hour TWA, with a skin notation. The ACGIH TLV® is 0.25 mg/ m3 TWA, with a skin notation. NIOSH considers this substance a potential human carcinogen and recommends that exposure be reduced to the lowest reliably detectable level. However, NIOSH concurs (Ex. 8-47, Table N6A) with the limit being proposed. OSHA is proposing to establish an 8-hour TWA limit of 0.25 mg/m3 and a skin notation in agriculture; this limit is consistent with OSHA's current limit for this substance in other sectors.

Aldrin is a nonflammable tan to dark-brown solid with a mild odor; it is a chlorinated naphthalene derivative that has been used extensively as an insecticide (Baselt 1980, p. 15; ACGIH 1986, p. 17). Aldrin is often found in the soil around buildings, where it has been used as a termiticide (Clayton and Clayton 1981, p. 3702). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

In animals, aldrin causes convulsions; in mice, it has caused liver tumors (Proctor, Hughes, and Fischman 1988, p. 61). The lethal dose in 50 percent (LD₅₀) of rats given aldrin by oral

administration is 67 mg/kg; acutely poisoned animals had tremors and convulsed before death (Clayton and Clayton 1981, p. 3703). Aldrin can be absorbed through the skin in lethal amounts; the dermal LD50 for this substance is 150 mg/kg (Clayton and Clayton 1981, p. 3703). Chronic feeding studies in rats involving dietary aldrin doses of 12.5 ppm parts of diet or 0.02 mg/kg/day showed that degenerative liver changes and increases in liver weight had occurred in these animals (Clayton and Clayton 1981, p. 3703).

Aldrin has been tested for carcinogenicity in mice and rats by the oral route of administration. In mice, the results of these studies were positive; mice developed a statistically significant increase in the incidence of malignant liver neoplasms (NIOSH 1978). Based on this evidence, the International Agency for Research on Cancer has concluded that there is limited evidence in animals that aldrin is a carcinogen (IARC 1987,

p. 88).

Workers exposed to aldrin at high concentrations exhibit the signs and symptoms of central nervous system effects: headache, nausea, dizziness, vomiting, myoclonic jerking of the limbs, and clonic-tonic convulsions; coma occurs in cases of severe poisoning (Proctor, Hughes, and Fischman 1988, p. 61). Five workers exposed to an aldrin concentration of 8.5 mg/m3 convulsed and showed myoclonic movements of the limbs (Proctor, Hughes, and Fischman 1988, p. 61). Workers exposed to an unspecified concentration of aldrin dust reported experiencing headaches, dizziness, nausea, and vomiting, but no clinical signs of liver damage were seen in these individuals (Clayton and Clayton 1981, p. 3707). Aldrin can be absorbed through the skin in toxic amounts, and the skin is believed to be a major route of exposure in occupational situations (Clayton and Clayton 1981, p.

The evidence described above demonstrates that aldrin produces liver damage as well as central nervous system effects and convulsions among exposed animals and humans; this substance can cause these effects by inhalation of the dust, ingestion of airborne particulates, or absorption through the skin when aldrin is present

in liquid vehicles.

OSHA therefore preliminarily finds that the absence of an exposure limit in longshoring and agriculture places workers in these occupational environments at significant risk of experiencing these material health impairments. The Agency believes that the establishment of an 8-hour TWA PEL of 0.25 mg/m³, and a skin notation. is necessary to substantially reduce this risk. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

ALLYL CHLORIDE

CAS: 107-05-1; Chemical Formula: CH2

= CHCH2Cl H.S. No. 1011

In construction and maritime, OSHA's current PEL for allyl chloride is 1 ppm (3 mg/m3) as an 8-hour TWA; there is no PEL in agriculture. The ACGIH TLV*s for allyl chloride are 1 ppm as an 8-hour TWA and 2 ppm as a 15-minute STEL. NIOSH has recommended exposure limits of 1 ppm as a 10-hour TWA and 3 ppm as a 15-minute ceiling limit. NIOSH also concurs (Ex. 8-47, Table N1) with the proposed limits. OSHA is proposing an 8-hour TWA limit of 1 ppm and a STEL of 2 ppm for this substance in construction, maritime, and agriculture. These are the limits recently established in general industry.

Allyl chloride is a colorless liquid with an unpleasant, pungent odor. This substance is used as a chemical intermediate and as a catalyst and modifier in the production of resins

(HSDB 1988).

Allyl chloride is an irritant, a liver, kidney, and pulmonary toxin, and, at high concentrations, a narcotic. This substance also has reproductive, embryotoxic, and developmental effects in experimental animals. The oral LD50 in rats is 64 mg/kg, and the lowest lethal concentration in the same species by inhalation is 290 ppm for 8 hours (RTECS 1990). In rabbits, the median lethal dose by percutaneous absorption is 2066 mg/kg (RTECS 1990). Rats exposed to a 16,000-ppm concentration for 2 hours showed signs of eye and nose irritation and became drowsy, weak, and uncoordinated before developing dyspnea and dying (Proctor, Hughes, and Fischman 1988, p. 63). Guinea pigs exposed to the same concentration for 1 hour showed the same exposure-related effects (Proctor, Hughes, and Fischman 1988, p. 63). Acutely poisoned animals showed liver and kidney damage and pulmonary hemorrhage at autopsy (Proctor, Hughes, and Fischman 1988, p. 63).

Single exposures to allyl chloride lasting only a few minutes at concentrations between 332 ppm and 32,000 ppm caused mucous membrane irritation in various laboratory animals; exposure to an 8-ppm concentration for 5 weeks caused kidney and liver damage (Adams, Spencer, and Irish 1940/Ex. 1-584). Other animal studies have confirmed this substance's liver and kidney toxicity in many species

(Torkelson, Wolf, Oyen, and Rowe 1959/ Ex. 1-691).

In the prior rulemaking, NIOSH (Ex. 150) commented that a recent bioassay (Santodonato et al. 1985) has shown that allyl chloride is also a tumor initiator in mice. This substance is a mutagen in bacterial test systems, both with and without activation (RTECS 1990). Several studies (RTECS 1990) have shown that, when administered to rats or mice during pregnancy, allyl chloride is embryotoxic and has both reproductive and developmental effects (RTECS 1990).

Exposures of 50 to 100 ppm allyl chloride for five minutes in humans caused eye and nose irritation, and fiveminute exposures below 25 ppm have been associated with pulmonary irritation (Shell Chemical Corp. 1974, as cited in Ex. 150). If the liquid is absorbed through the skin of humans, it causes pain in the area of contact that is described as deep-seated (Clayton and Clayton 1981, p. 3569). Humans exposed to concentrations of 1 to 113 ppm showed abnormal liver test results (Hausler and Lenich 1968/Ex. 1-1035). and there is a report that workers exposed to a 3-mg/m3 (1 ppm) concentration showed signs of kidney dysfunction (Clayton and Clayton 1981,

Chinese factory workers exposed to 0.8 to 2100 ppm allyl chloride for periods ranging from 2.5 months to 5 years developed weakness, paresthesia, pain, and numbness and sensory impairment in the extremities (Proctor, Hughes, and Fischman 1988, p. 63). Workers at another factory who were exposed to 0.06 to 8 ppm for 1 to 4.5 years showed lesser signs and symptoms (Proctor, Hughes, and Fischman 1988, p. 63).

Based on this evidence in humans and animals, OSHA is proposing to add a 2ppm STEL to the current 8-hour TWA limit of 1 ppm in construction and maritime and is also proposing to extend both limits to agriculture. The Agency preliminarily concludes that both TWA and STEL limits are necessary to protect workers in these sectors from the significant risks of kidney and liver damage and neuropathic effects that are potentially associated with exposure to this substance. OSHA considers these effects material impairments of health and believes that the proposed PELs are necessary to reduce this significant risk. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

CARBON TETRABROMIDE CAS: 558-13-4; Chemical Formula: CBr₄ H.S. No. 1072

OSHA has no limit for carbon tetrabromide in construction, maritime, or agriculture. The 1987-1988 ACGIH TLV®s for this substance are 0.1 ppm as an 8-hour TWA and 0.3 ppm as a 15minute STEL. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the 0.1 ppm 8-hour TWA limit and 0.3 ppm 15minute STEL OSHA is proposing for construction, maritime, and agriculture. These are the limits recently established for this substance in general industry.

At room temperature, pure carbon tetrabromide is a colorless. nonflammable solid; however, the commercial product is usually yellowbrown in color. This substance finds use as a chemical intermediate.

Carbon tetrabromide is considered a highly toxic material (Clayton and Clayton 1981, p. 3479). In addition to liver toxicity, carbon tetrabromide causes irritation of the eyes and upper respiratory tract, and kidney and lung damage (Clayton and Clayton 1981, p. 3479). Even at low levels, carbon tetrabromide is a powerful lacrimator (Clayton and Clayton 1981, p. 3479). In contact with the eyes, the pure material causes irreversible corneal damage; skin contact causes mild irritation and redness (Clayton and Clayton 1981, p. 3479). The lowest lethal dose in rats by oral administration is 1000 mg/kg, and the intravenous LD50 in mice is 56 mg/kg (RTECS 1990). Rats exposed to a 0.07 to 74 ppm concentration for 4 hours daily over a 4-month period developed metabolic changes in the liver (Clayton and Clayton 1981, p. 3479). Carbon tetrabromide's hepatotoxic effects include both fatty infiltration and necrosis. Rats exposed to carbon tetrabromide by inhalation for 7 hours per day, 5 days per week for 6 months showed no effects, while repeated exposures to higher concentrations caused fatty changes and degeneration of the liver discernible at autopsy (Torkelson and Rowe 1981a/Ex. 1-974; Clayton and Clayton 1981, pp. 3479-3480).

OSHA is proposing a 0.1-ppm 8-hour TWA limit and a 0.3-ppm 15-minute STEL for carbon tetrabromide in construction, maritime, and agriculture. OSHA preliminarily concludes that these limits are necessary to protect workers in these sectors against the significant risk of hepatotoxic, irritant, and kidney and lung effects associated with exposure to this substance. OSHA considers such effects material health impairments and believes that the proposed PELs will substantially reduce these risks. In addition, promulgation of these limits will make OSHA's PELs for

this substance consistent across all regulated sectors.

CHLORDANE

CAS: 57-74-9; Chemical Formula:

C10HeCle H.S. No. 2028

OSHA's PEL for chlordane in general industry, construction, and maritime is 0.5 mg/m3 as an 8-hour time-weighted average (TWA), with a skin designation; there is no PEL in agriculture for this substance. The 1987-1988 ACGIH TLV®-TWA for chlordane is 0.5 mg/m3 and the TLV*-STEL is 2 mg/m3, with a skin designation; NIOSH has no REL but concurs (Ex. 8-47, Table N6A) with the limit being proposed. OSHA is proposing both an 8-hour TWA PEL of 0.5 mg/m3 and a skin designation for chlordane in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all regulated sectors.

Chlordane is an odorless, viscous liquid that ranges from colorless to amber in appearance (Hawley's 1987, p. 258; ACGIH 1986; p. 114). This substance is used almost exclusively as an insecticide against termites. It was formerly used as an acaricide and to control grubs, ants, webworms, armyworms, cutworms, chiggers, and leafhoppers (HSDB 1986; Hawley's 1987, p. 258). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide ACT

Chlordane is a convulsant and liver toxin in humans and animals and a liver carcinogen in mice (Proctor, Hughes, and Fischman 1988, p. 126). The oral LD50 in rats is 283 mg/kg; the LC50 in cats is 100 mg/m3 for 4 hours; and the dermal LD₅₀ in rabbits is 780 mg/kg (RTECS 1990). Acutely poisoned animals convulse before death (Hayes 1982, p. 229). Animals given daily oral doses of 50 mg/kg chlordane for 2 weeks died, while those given 25 mg/kg for the same period did not (ACGIH 1986, p. 114). At autopsy, rats fed 0.008, 0.15, or 0.32 percent chlordane for 407 days showed liver damage; other organs appeared unaffected (ACGIH 1986, p. 114).

During a 2-year study in rats fed chlordane at 5, 10, 30, 150, or 300 ppm, the following effects were reported: the higher doses of 150 and 300 ppm caused notable growth retardation, marked liver and kidney damage, marked lung damage (300 ppm), and mild lung injury (150 ppm). Liver damage was slight at 30 ppm and minimal at 10 ppm; no liver damage was reported in those animals fed at the 5-ppm level (Clayton and Clayton 1981, p. 3721). Chlordane has

been tested in bioassays in mice and rats. In mice, oral administration caused hepatocellular carcinomas in mice of both sexes; in rats, the results were inconclusive. Based on this evidence. the International Agency for Research on Cancer (IARC) has concluded that the evidence for the carcinogenity of chlordane in animals is sufficient (IARC 1974, p. 58).

The signs and symptoms associated with acute oral or dermal exposure of humans to chlordane are loss of appetite, irritability, hyperexcitability, vomiting, tremors, and convulsions, and, if overexposure is severe, death (Clayton and Clayton 1981, p. 3718). Skin and mucous membrane irritation have been reported from contact with technical grade chlordane, but this effect may have been due to contamination of the chlordane with hexachlorocyclopentadiene (Proctor. Hughes, and Fishman 1988, p. 126). Chlordane is rapidly absorbed through the skin and has caused at least one fatality by this route (Proctor, Hughes, and Fishman 1988, p. 126). Workers exposed to chlordane and aldrin at a 5mg/m3 concentration for 1 to 3 years showed no adverse effects (ACGIH 1986, p. 114). After accidental ingestion, individuals convulse and experience nausea and vomiting; confusion, excitability, incoordination, and coma may also occur (Hayes 1982, p. 230). A formulation plant worker who spilled chlordane on her abdomen and thighs died after experiencing convulsions (Hayes 1982, p. 230). IARC reports that case reports in humans suggest a relationship between exposure to chlordane, alone or in combination with other compounds, and the development of blood dyscrasias (IARC 1974, p. 58).

Based on this evidence in humans and amimals, OSHA preliminarily concludes that agricultural workers exposed to chlordane at the levels permitted by the absence of a limit are at significant risk of experiencing convulsions and liver damage, and perhaps death. The Agency believes that establishing a PEL of 0.5 mg/m3 as an 8-hour TWA, and a skin designation, is necessary to protect workers in agriculture from these significant risks. In addition. promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. CHLORINATED DIPHENYL OXIDE CAS: 55720-99-5; Chemical Formula:

C₆H₂Cl₃OC₆H₂Cl₃ (Approximate)

OSHA's limit for chlorinated diphenyl oxide in general industry, construction, and maritime workplaces is 0.5 mg/m3

as an 8-hour time-weighted average. There is no limit for this substance in agriculture. In 1987-1988, the ACGIH had a TLV®-TWA of 0.5 mg/m3 and TLV®-STEL 2.0 mg/m3 for chlorinated diphenyl oxide; NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing to establish a permissible exposure limit (PEL) of 0.5 mg/m3 as an 8-hour TWA for chlorinated diphenyl oxide in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all sectors.

The physical form of chlorinated diphenyl oxide varies from a viscous, colorless, oily liquid to a yellowish, waxy semisolid, depending on the chlorine equivalents in the compound's formula. The chlorine equivalents vary from 1 (monochloro-) to 6 (hexachloro-) diphenyl oxide (ACGIH 1986, p. 116; Proctor, Hughes, and Fischman 1988, p. 128). Chlorinated diphenyl oxide is used as a solvent; an intermediate in the organic synthesis of pesticides, wood preservatives, hydraulic fluids, corrosion inhibitors, thermal lubricants, etc.: and as a dielectric fluid in the electrical industry (Proctor, Hughes, and Fischman 1988, p. 128; NIOSH/OSHA Occupational Health Guideline 1981, p.

Exposure to chlorinated diphenyl oxide causes chloracne (acneform dermatitis) and cumulative liver damage in animals (Proctor, Hughes, and Fischman 1988, p. 128). In guinea pigs, the lowest lethal dose by oral administration is 50 mg/kg (RTECS 1989). Application of hexachlorodiphenyl oxide to the skin of rabbits caused marked irritation and epithelial hyperplasia (Clayton and Clayton 1982, p. 2550). Repeated application to the skin of rabbits caused systemic poisoning, manifested at autopsy by liver injury (Clayton and Clayton 1982, p. 2550).

Systemic effects have not been reported in humans exposed to chlorinated diphenyl oxides. However, acneform dermatitis (chloracne) has occurred as a result of industrial exposures (Proctor, Hughes, and Fischman 1988, p. 128). Affected individuals develop comedones and cysts on the face, ears, neck, shoulders, arms, chest, abdomen, and scrotum (Proctor, Hughes, and Fischman 1988, p. 128).

Based on this evidence, OSHA preliminarily concludes that the absence of a limit for chlorinated diphenyl oxide poses a significant risk of chloracne and liver damage to workers in agriculture who are exposed to this substance. The Agency believes that the proposed PEL for chlorinated diphenyl oxide of 0.5

mg/m3 as an 8-hour TWA is necessary to substantially reduce these significant risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. CHLOROBENZENE

CAS: 108-90-7; Chemical Formula: C6H5Cl

H.S. No. 2033

OSHA's PEL for chlorobenzene in general industry, construction, and maritime is 75 ppm as an 8-hour timeweighted average (TWA); there is no PEL in agriculture. The 1987-1988 ACGIH TLV*-TWA for chlorobenzene is 75 ppm; there is no NIOSH REL for this substance. OSHA is proposing an 8hour TWA limit of 75 ppm for chlorobenzene in agriculture. Promulgation of this limit will make the PEL for chlorobenzene consistent across all regulated sectors.

Chlorobenzene is a colorless to paleyellow liquid with an odor similar to that of almonds (ACGIH 1986, p. 123; HSDB 1986). It is used as a chemical intermediate in the manufacture of DDT, aniline, phenol, ortho- and parachlorobenzene, and dyestuffs, and as a solvent in the manufacture of adhesives, paints, polishes, waxes, diisocyanates, pharmaceuticals, and natural rubber. It is also used as a fiber swelling agent and dye carrier in the textile industry and as a tar and grease remover in cleaning and degreasing operations

(HSDB 1986). Chlorobenzene causes irritation of the eves and nose and narcosis in both animals and humans; in laboratory animals, chronic exposure causes liver, kidney, and lung damage (ACGIH 1986, p. 123(89); Proctor, Hughes, and Fischman 1988, p.133; Clayton and Clayton 1982, pp. 3605-3610). The oral LD50 in rats is 2910 mg/kg (RTECS 1989). The dermal toxicity of chlorobenzene is reported to be low; for guinea pigs, dermal doses of 10 ml/kg were nonlethal (ACGIH 1986, p. 123.3(89)). Subcutaneous injections of 7 to 8 g/kg resulted in the death of injected rats within a few hours of administration; necrosis of the liver and kidneys was observed in these animals at autopsy (Clayton and Clayton 1982, p. 3605). Exposure to an 8000-ppm concentration of chlorobenzene caused eye and nose irritation, followed by severe narcosis in cats after 30 minutes; death occurred within 2 hours of exposure (Proctor, Hughes, and Fischman 1988, p. 133). At a concentration of 1200 ppm for an unspecified time, cats showed narcotic effects; at a concentration of 200 to 660 ppm, exposure caused no significant effects even after several hours (Clayton

and Clayton 1982, p. 3605). At autopsy, histopathological changes were seen in the liver, kidneys, and lungs of laboratory animals exposed to a 1000ppm concentration of chlorobenzene for 7 hours/day, 5 days/week for 44 days (for a total of 32 exposures). When the concentration was reduced to 475 ppm. the changes seen at the higher concentrations occurred but were less severe (Clayton and Clayton 1982, p. 3607). Mice exposed to a 544-ppm concentration of chlorobenzene for 7 hours/day for 3weeks or 22 ppm for 7 hours/day for 3 months suffered from leukopenia and depressed bone marrow activity (Proctor, Hughes, and Fischman 1988, p. 133). Oral toxicity studies in rats that were dosed 5 days/week for 192 days (for a total of 137 doses) showed the following effects: doses of 0.144 g/kg and 0.288 g/kg both caused slight changes in the liver and a significant increase in liver and kidney weights. while a dose of 0.0144 g/kg caused no observable effects (Clayton and Clayton 1982, pp. 3606-3607).

In humans, eye and nose irritation begins on exposure to concentrations of 200 ppm (Proctor, Hughes, and Fischman 1988, p. 133). Contact of the skin with liquid chlorobenzene causes mild skin irritation; prolonged contact may lead to dermatitis (Proctor, Hughes, and Fischman 1988, p. 133). A study of 52 workers exposed to chlorobenzene reported that many of the workers who had been exposed to chlorobenzene (concentration unspecified) for 1 to 2 years experienced headache, dizziness, sleepiness, and dyspeptic disorders. Some of these workers showed spastic muscle contractions and paresthesia of the extremities when tested clinically, and others suffered from vasovegetative instability (Clayton and Clayton 1982, pp. 3610-3611).

Based on this evidence, OSHA preliminarily concludes that agricultural workers exposed to chlorobenzene at the levels permitted by the absence of a limit are at significant risk of experiencing eye and nose irritation; liver, lung, and kidney damage; and narcosis. The Agency believes that establishing a PEL of 75 ppm as an 8hour TWA is necessary to protect workers in agriculture from these significant occupational risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

CHLORODIPHENYL (42% CHLORINE)

CAS: 53469-21-9; Chemical Formula: C12H7Cl3 (Approximate) H.S. No. 2035

In general industry, construction, and maritime, OSHA's permissible exposure limit (PEL) for chlorodiphenyl (42% chlorine) is 1 mg/m3 as an 8-hour timeweighted average (TWA), with a skin designation. There is no limit for this substance in agriculture. The 1987-1988 ACGIH TLV®-TWA was 1 mg/m3 and the TLV*-STEL was 2 mg/m3, with a skin designation. NIOSH considers this substance a potential human carcinogen and recommends reducing exposure to the lowest feasible concentration (0.001 mg/m³). OSHA is proposing an 8-hour TWA limit of 1 mg/m3, with a skin designation, for chlorodiphenyl (42% chlorine) in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all regulated sectors.

Chlorodiphenyl (42% chlorine) is a polychlorinated biphenyl (PCB); it is a clear, colorless to straw-colored liquid with a mild hydrocarbon odor. The production and sale of PCBs was discontinued by the EPA in 1977, but this substance is still found in transformers and capacitors that have remained in use (HSDB 1988; Merck 1983, p. 1091; ACGIH 1986, p. 128).

Chlorodiphenyl (42% chlorine) is toxic to the liver, is an irritant of the eyes and mucous membranes, and causes acneform dermatitis (chloracne). It is carcinogenic, embryotoxic, and teratogenic in laboratory animals (ACGIH 1986, p. 128; Proctor, Hughes, and Fischman 1988, p. 136; IARC 1987, p. 324). The oral LD50 for chlorodiphenyl (42% chlorine) in rats ranges from 4250 to 8700 mg/kg, and the dermal LD50 in rabbits ranges from 800 to 1300 mg/kg [IARC 1978, p. 69; RTECS 1990]. Monkeys given 300 ppm of this substance in their diet for 90 days showed hair loss, chloracne, subcutaneous edema, liver hypertrophy, and hyperplasia of the gastric mucosa (Gosselin, Smith, and Hodge 1984, p. II-171). Chlorodiphenyl (42% chlorine) is rapidly absorbed through the skin and accumulates in lipid-rich tissues such as those of the brain. Exposure to chlorodiphenyl (42% chlorine) by any route produces skin changes that may lead to acneform dermatitis and sticky eye discharge in laboratory animals (Proctor, Hughes, and Fischman 1988, p. 137; Grant 1986, p. 750). Skin contact results in depletion of the natural oils of the skin, which leads to local redness and skin cracking (AIHA 1965). This substance is toxic to the liver, causing fatty degeneration, cell death, hypertrophy, and induction of microsomal enzymes (Proctor, Hughes, and Fischman 1988, p. 138; IARC 1978, p. 68; Gosselin, Smith, and Hodge 1984, p.

II-171 to II-172). Rabbits fed 30 mg/m³ chlorodiphenyl (42% chlorine) for 14 weeks developed enlarged livers, and rats fed 100 ppm for as long as 10 months showed no clinical liver effects but did have enlarged hepatocytes at autopsy (HSDB 1988). Although cats, rabbits, and rats showed no ill effects when exposed for 7hours/day to an 8.6-mg/m³ concentration over a 24-day period, guinea pigs similarly exposed demonstrated poor growth (AIHA 1965).

Workers exposed to 0.1 mg/m3 chlorodiphenyl (42% chlorine) for several months developed mild-tomoderate skin irritation and chloracne. and exposure to a level of 10 mg/m3 was reported to be intolerably irritating (Proctor, Hughes, and Fischman 1988, p. 137). Workers exposed to chlorodiphenyl (42% chlorine) at concentrations below 0.1 mg/m3 have not been known to develop chloracne. Occupationally exposed individuals have shown clinical evidence of liver injury, and deaths caused by toxic hepatitis have occurred in workers exposed to a mixture of PCBs and chlorinated naphthalenes (Proctor, Hughes, and Fischman 1988, p. 137). The International Agency for Research on Cancer (IARC) has concluded that the evidence for chlorodiphenyl-induced carcinogenicity in humans is limited, although studies in humans do support an association between cancer and exposure to these substances (IARC 1987, p. 324). A study of workers in Italy who had been exposed to a mixture of chlorodiphenyls (54% and 42% chlorine) reported an increase in cancer mortality among these workers; male workers had a significant excess of gastrointestinal tract tumors (including one liver tumor) and female workers had a significant excess of hematological tumors (IARC 1987, Supplement 7, p. 323). Several thousand Japanese and Taiwanese citizens who accidentally ingested chlorodiphenyl (42% chlorine) over several months developed swelling of the upper eyelids, excessive eye discharge, follicular keratosis, gastrointestinal problems, various nervous symptoms, peripheral neuropathy, darkening of the skin, and chronic bronchitis; babies born to women who became pregnant during this period also showed many of these signs (IARC 1978, pp. 80-84).

Based on this evidence in humans and animals, OSHA preliminarily concludes that agricultural workers exposed to chlorodiphenyl (42% chlorine) at the levels permitted by the absence of a limit are at significant risk of irritation, chloracne, liver damage, and, perhaps, of cancer. The Agency believes that

establishing a PEL of 1 mg/m³ as an 8-hour TWA, and a skin designation, will substantially reduce significant risk for workers in agriculture. OSHA recognizes that a lower limit may be needed for chlorodiphenyl (42% chlorine). As discussed above, however, the principal purpose of this rulemaking is to extend to all workers the protection given to workers in general industry. The need for a change to the limit for this substance will be considered for all workers in a future update of the Agency's PELs.

CHLORODIPHENYL (54% CHLORINE) (PCB)

CAS: 11097-69-1; Chemical Formula: C₁₂H₅Cl₅ H.S. No. 2036

In general industry, construction, and maritime, OSHA's permissible exposure limit (PEL) for chlorodiphenyl (54% chlorine) is 0.5 mg/m3 as an 8-hour timeweighted average (TWA), with a skin designation. There is no limit in agriculture for this substance. The 1987-1988 ACGIH TLV®-TWA was 0.5 mg/m3 and the TLV*-STEL was 1 mg/m3, with a skin designation. NIOSH considers this substance a potential human carcinogen and recommends reducing exposure to the lowest feasible concentration (0.001 mg/m³). OSHA is proposing to establish an 8-hour TWA limit of 0.5 mg/m3, with a skin designation, for chlorodiphenyl (54% chlorine) in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all regulated sectors.

Chlorodiphenyl (54% chlorine) is a polychlorinated biphenyl (PCB); it is a pale yellow, viscous liquid with a mild hydro-carbon odor. The production and sale of PCBs was halted by the EPA in 1977, but this substance is still found in transformers and capacitors that have remained in use (ACGIH 1986, p. 129; Merck 1983, p. 1091).

Exposure to chlorodiphenyl (54% chlorine) causes irritation, chloracne, and liver damage. In laboratory animals, this substance is carcinogenic, embryotoxic, and teratogenic. The oral LD₅₀ in rats is 1010 mg/kg, and the intravenous LD50 in the same species is 358 mg/kg (RTECS 1990). Acutely poisoned rats develop diarrhea, ataxia. loss of pain response, and narcosis (Gosselin, Smith, and Hodge 1984, p. II-171). The minimum lethal dermal dose in rabbits is 1.5 g/kg (Proctor, Hughes, and Fischman 1988, p. 142). Repeated dermal application caused hyperplasia and hyperkeratosis in the epithelium, liver and kidney damage, and atrophy of the thymus (Gosselin, Smith, and Hodge

1984, p. II-17). Rats exposed to a 5.4-mg/ m3 concentration of chlorodiphenyl (54% chlorine) for 7 hours/day for 4 months showed an increase in liver weight and, at autopsy, liver damage (Proctor, Hughes, and Fischman 1988, p. 142). Dietary administration of chlorodiphenyl (54% chlorine) in mice and rats has caused a significant excess of benign and malignant liver tumors in several bioassays. Rats also developed interstitial metaplasia and a low. statistically nonsignificant incidence of stomach adenocarcinomas (IARC 1987, Supplement 7, p. 322]. The International Agency for Research on Cancer (IARC) has concluded that the evidence for the carcinogenicity of chlorodiphenyl (54% chlorine) in animals is sufficient (IARC 1987, Supplement 7, p. 322). Chlorodiphenyl (54% chlorine) also has caused fetotoxicity, maternal death, abortion, and stillbirth when administered orally to rabbits at a dose of 12.5 mg/kg (Clayton and Clayton 1981, p. 3667). A dose-related increase in the number of malformed offspring occurred in pigs and rats fed chlorodiphenyl (54% chlorine) at a dose of 1 mg/kg/day (Proctor, Hughes, and Fischman 1988, p. 143). Chlorodiphenyl (54% chlorine) is mutagenic in mammalian test systems (RTECS 1990).

Workers exposed to 0.1 mg/m3 chlorodiphenyl for several months developed mild-to-moderate irritation of the skin and chloracne; however, exposure to chlorodiphenyls at concentrations below 0.1 mg/m3 did not produce chloracne (Proctor, Hughes, and Fischman 1988, p. 140). Exposure to a 10mg/m3 concentration is reported to be intolerably irritating (Proctor, Hughes, and Fischman 1988, p. 140). Workers who have PCB-induced chloracne also often show clinical evidence of liver disease, and several workers have died of toxic hepatitis after exposure to PCBs and chlorinated naphthalenes (Proctor, Hughes, and Fischman 1988, p. 140). Studies in humans have shown that workers exposed to chlorodiphenyl (54% chlorine) in electrical capacitor filling and sealing operations have experienced a slight increase in the incidence of cancer, particularly in melanomas of the skin; another study showed an excess number of deaths due to cancer of the liver and biliary passages in chlorodiphenyl-exposed workers (IARC 1987, Supplement 7, p. 323). A study of workers in Italy who had been exposed to a mixture of chlorodiphenyls (54% and 42% chlorine) reported a significant increase in cancer mortality among these workers; male workers had a significant excess of gastrointestinal tract tumors (including

one liver tumor) and female workers had a significant excess of hematological tumors (IARC 1987, Supplement 7, p. 323). IARC has concluded that the available human studies suggest an association between cancer and exposure to PCBs and notes that the increased risk of hepatobiliary cancer is consistent across different studies (IARC 1987, Supplement 7, p. 324).

Based on this evidence in humans and animals, OSHA preliminarily concludes that agricultural workers exposed to chlorodiphenyl (54% chlorine) at the levels permitted by the absence of a limit are at significant risk of irritation, chloracne, liver damage, and, perhaps, of cancer. The Agency believes that establishing a PEL of 0.5 mg/m3 as an 8hour TWA, and a skin designation, will substantially reduce significant risk for workers in agriculture. OSHA recognizes that a lower limit may be needed for chlorodiphenyl (54% chlorine). As discussed above, however, the principal purpose of this rulemaking is to extend to all workers the protection given to workers in general industry. The need for a change to the limit for this substance will be considered for all workers in a future update of the Agency's PELs. o-CHLOROSTYRENE

CAS: 2039-87-4; Chemical Formula: C₈H₇Cl H.S. No. 1089

In construction, maritime, and agriculture, OSHA has no limit for o-chlorostyrene. The ACGIH TLV*s are an 8-hour TWA of 50 ppm and a STEL of 75 ppm; NIOSH has no REL for this substance but concurs (Ex. 8–47, Table N1) that the proposed limits are appropriate. OSHA is proposing a 50-ppm TWA PEL and a 75-ppm STEL for o-chlorostyrene in construction, maritime, and agriculture. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

o-Chlorostyrene is a colorless liquid at room temperature. This substance is used as a chemical intermediate and in the manufacture of polymers (Sittig 1985,

o-Chlorostyrene is an irritant of the eyes and skin on acute exposure, and chronic exposure causes kidney as well as liver damage (New Jersey Fact Sheet 1986, pp. 1, 2). In an unpublished report, the Dow Chemical Company (1973a, as cited in ACGIH 1986/Ex.1-3, p. 136) describes the results of an o-chlorostyrene inhalation study in rats, rabbits, guinea pigs, and dogs. Dow exposed the animals to an average o-chlorostyrene concentration of 101 ppm for 7 hours daily, 5 days per week, for a

total of 130 exposures in 180 days. No adverse effects were observed in any species in terms of appearance, growth, behavior, mortality, hematology, BUN, alkaline phosphatase, SGPT, BSP, organ weights, or gross pathology (Dow Chemical Company 1973a, as cited in ACGIH 1986/Ex. 1–3, p. 136). Microscopic examination of animal tissue revealed a somewhat higher incidence of pathological changes in the liver and kidneys (Dow Chemical Company 1973a, as cited in ACGIH 1986, Ex. 1–3, p. 136).

A paper by Coulter, Kehde, and Hiscock (1971) reports that o-chlorostyrene has toxicological properties that are similar to those of styrene; since human volunteers exposed for 1 to 7 hours to the vapor of styrene at concentrations of 100 ppm have shown narcotic effects (Stewart, Dodd, Baretta, and Schaffer 1968, Ex. 1–380), exposure to o-chlorostyrene should be maintained at concentrations below this level at all times.

Based on this evidence, OSHA is proposing PELs for o-chlorostyrene in construction, maritime, and agriculture of 50 ppm as an 8-hour TWA and 75 ppm as a 15-minute STEL. The Agency preliminarily concludes that both of these limits will protect workers in these sectors from the significant risks of liver and kidney damage and narcosis to which they could potentially be exposed in the absence of an OSHA limit. OSHA believes that these health effects constitute material health impairments and that the proposed TWA and STEL limits are necessary to substantially reduce these significant occupational risks. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

CYCLOHEXANONE
CAS: 108-94-1; Chemical Formula:
C₀H₁₀O
H.S. No. 1108

OSHA's limit for cyclohexanone in construction and maritime is 50 ppm as an 8-hour TWA. The ACGIH 1987–1988 TLV* for this substance is 25 ppm as an 8-hour TWA, with a skin notation. NIOSH has a REL of 25 ppm as a 10-hour TWA for cyclohexanone and also concurs (Ex. 8-47, Table N1) with the limit OSHA is proposing in construction, maritime, and agriculture, which is an 8-hour TWA PEL of 25 ppm, with a skin notation. This is the limit recently established for this substance in general industry.

Cyclohexanone is a white to pale yellow, oily liquid with an odor similar to that of acetone and peppermint. This substance is used as a solvent in metal degreasing operations and in the production of acetates, resins, rubber, waxes, shellacs, nitrocellulose, and pesticides (ACGIH 1986, p. 159; HSDB 1986). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

In addition to liver damage, exposure to cyclohexanone causes eye, nose, and upper respiratory tract irritation and, at high concentrations, narcosis in experimental animals. The oral LD50 in rats is 1535 mg/kg, and the LCso in the same species is 8000 ppm for 4 hours (RTECS 1990). The lowest reported dermal LD50 in rabbits is 948 mg/kg (RTECS 1990). Cyclohexanone has been studied in several experimental animal species. A concentration of 2000 ppm inhaled for four hours was lethal to one of six rats; at 4000 ppm, all of the exposed animals died (Smyth, Carpenter, Weil et al. 1969/Ex. 1-442). Rabbits showed marked irritation and some corneal injury when undiluted cyclohexanone was instilled into the eye (Carpenter and Smyth 1946/Ex. 1-859); applied to the skin of rabbits, this substance caused mild irritation (RTECS 1990). Guinea pigs exposed to the vapor at a concentration of 4000 ppm for 6 hours showed narcotic symptoms, lacrimation, salivation, depression of body temperature and heart rate, and corneal opacity (Specht, Miller, Valaer, and Sayers 1940/Ex. 1-1179). At autopsy, rabbits exhibited degenerative changes of the liver and kidneys after 50 daily 6-hour inhalation exposures to 190 ppm (Treon, Crutchfield, and Kitzmiller 1943b/Ex. 1-394). Exposures to a 309ppm concentration of cyclohexanone on the same regimen caused conjunctival congestion, while exposures to a 3000ppm concentration of cyclohexanone were lethal to some of the exposed rabbits (Treon, Crutchfield, and Kitzmiller 1943b/Ex. 1-394). When the cyclohexanone concentration was increased to approximately 3082 ppm. the rabbits lost coordination, developed difficult breathing, and showed signs of narcosis (Treon, Crutchfield, and Kitzmiller 1943b/Ex. 1-394).

In humans, Nelson and co-workers (1943/Ex. 1–66) reported that irritation caused by exposure to cyclohexanone was intolerable at 50 ppm; however, 25 ppm was not objectionable to most subjects in 3- to 5-minute exposures (Nelson, Enge, Ross et al. 1943/Ex. 1–66). Marked eye and upper respiratory tract irritation occurred at a concentration of 75 ppm (Clayton and Clayton 1981, p. 4782).

OSHA is proposing to add a skin notation for cyclohexanone based on this substance's ability to cause systemic toxicity via absorption through the skin. In the prior Air Contaminants rulemaking, one commenter (Ex. 3-678) stated that, in his opinion, there was no evidence for cyclohexanone's dermal toxicity, and thus that no skin notation was necessary. In response to this commenter, OSHA pointed to the dermal LDso in rabbits of 948 mg/kg (RTECS 1990) and to the Agency's policy of establishing skin notations for substances having dermal LDsos in rabbits of 1000 mg/kg or less.

Based on this evidence, OSHA is proposing an 8-hour TWA PEL for cyclohexanone of 25 ppm, and a skin notation, in construction, maritime, and agriculture. The Agency has preliminarily determined that this limit and notation will protect workers in construction, maritime, and agriculture from the significant risks of liver and kidney damage, skin and respiratory tract irritation, and percutaneous absorption associated with exposure to this substance. OSHA considers these effects material health impairments and believes that the proposed PEL is necessary to substantially reduce these risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

1,1-DICHLOROETHANE
CAS: 75-34-3; Chemical Formula:
CH₃CHCl₂
H.S. No. 1126

OSHA's PEL for dichloroethane in general industry, construction, and maritime is 100 ppm as an 8-hour TWA. There is no PEL in agriculture. The ACGIH TLV*s for this substance are 200 ppm as an 8-hour TWA and 250 ppm as a 15-minute STEL, respectively. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. In agriculture, OSHA is proposing an 8-hour TWA PEL of 100 ppm for 1.1-dichloroethane. Promulgation of this limit will make OSHA's PEL for dichloroethane consistent across all regulated sectors.

1,1-Dichloroethane, also called ethylidene chloride, is a colorless, mobile, combustible liquid with an odor like that of chloroform (ACGIH 1986, p. 184; Hawley's 1987, p. 494). This substance is used as a chemical intermediate and also finds limited use as a solvent. It is also used as a fumigant and insecticide (HSDB 1990). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under

the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Dichloroethane is a narcotic and liver and kidney toxin; exposure to high concentrations may also cause lung damage. Reproductive effects and tumors have been reported in a few animal studies involving dichloroethane (RTECS 1990). The oral LDso in rats is 725 mg/kg (RTECS 1990). Rats died after exposure to dichloroethane concentrations of 32,000 ppm for 2.5 hours, but reducing the exposure interval to 30 minutes resulted in the survival of all exposed animals (AIHA 1971). Rats, guinea pigs, rabbits, and dogs exposed to 1000 ppm for 7 hours/ day for 5 days/week for 8 months showed no gross or microscopic alterations at autopsy; however, a single exposure to concentrations of 8,000 ppm and above for 7 hours caused liver and kidney changes discernible at autopsy (AIHA 1971). Rats inhaling 6000 ppm for 7 hours/day on gestation days 6-15 had litters with an increased incidence of retarded fetal development, including delayed sternabral ossification (Schwetz et al. 1974). An NCI gavage bioassay (NCI 1978) in rats and mice failed to show conclusive evidence of carcinogenicity in these species. although marginal increases in mammary adenocarcinomas and hemangiosarcomas were seen in female rats and female mice developed a statistically significant increase in the incidence of endometrial stromal polyps.

In humans, exposure to very high concentrations of this substance causes deep narcosis, as evidenced by dichloroethane's former use as a human anesthetic (Proctor, Hughes, and Fischman 1988, p. 188). However, no other information on effects in humans is available.

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 100 ppm in agriculture. The Agency believes that this PEL is necessary to protect workers in this sector from experiencing the narcotic and hepatotoxic effects potentially associated with exposure to this substance. OSHA considers these effects material impairments of health and believes that the PEL will substantially reduce the significant risk that agricultural workers will experience these effects. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

DIMETHYL ACETAMIDE
CAS: 127-19-5; Chemical Formula:
CH₃CON(CH₃)₃
H.S. No. 2065

In general industry, construction, and maritime, OSHA's permissible exposure limit for dimethyl acetamide is 10 ppm as an 8-hour TWA, with a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. There is no OSHA limit for dimethyl acetamide in agriculture, and NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. The ACGIH has an 8-hour TLV*-TWA of 10 ppm, with a skin notation, for dimethyl acetamide. OSHA is proposing to establish a permissible exposure limit of 10 ppm as an 8-hour TWA, and a skin notation, for this substance in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all regulated sectors.

Dimethyl acetamide is a colorless liquid with a faint ammonia-like odor (Genium MSDS 1989, No. 458). Dimethyl acetamide finds use as a solvent for plastics, resins, and gums; as a catalyst; as a paint remover; and as a high-purity solvent for crystallization and purification (Hawley's 1987, p. 409). This substance has also been used in human medicine as a neoplastic agent (HSDB

1985).

Dimethyl acetamide causes skin irritation and liver damage in animals and humans; this substance has also been shown to be a teratogen in animals. The oral LDso in rats is 5000 mg/kg; for mice, it is 4620 mg/kg (RTECS 1987). The dermal LDso in rabbits is 2240 mg/kg (RTECS 1987). Rabbits experienced mild skin irritation after contact of the liquid with the skin for 24 hours. Dermal application of 9600 mg/kg dimethyl acetamide caused behavioral symptoms and pulmonary and liver effects in mice, indicating that this substance can be absorbed through the skin in toxic amounts (RTECS 1987). Dimethyl acetamide caused corneal necrosis when applied to the rabbit eye in undiluted form (Smyth 1962). Rats showed nasal irritation, an increase in blood cholesterol, and liver hypertrophy after being exposed to a 288-ppm concentration for 6 hours/day for 2 weeks; there was also evidence of testicular atrophy 2 weeks after exposure ceased (Kelley et al. 1984). Dogs exposed to repeated dermal applications of 4 mg/kg for 6 weeks exhibited severe fatty infiltration of the liver at autopsy (Kelley et al. 1984). Rats repeatedly exposed to a concentration of 195 ppm for 6 months showed focal necrosis of the liver at post mortem; when the concentration was reduced to 40 ppm for 6 months, no adverse effects were seen (Horn 1961). A reproductive study in male rats involving inhalation

exposure to 40, 120, or 400 ppm dimethyl acetamide for 8 hours/day, 5 days/week for 43 exposures failed to find reproductive effects in any of the animals tested; however, significant increases in liver weight and in liver/ body weight ratios were seen in animals in the 120- and 400-ppm groups (Wang, Kier, and Pounds 1989). Teratogenic effects (such as encephalocele and diffuse subcutaneous edema) were observed among fetuses of rats that had been dermally exposed on gestation days 10 and 11 to a total dimethyl acetamide dose of 2400 mg/kg (Stula and Krauss 1977). Developmental abnormalities also occurred in the fetuses of rabbits given oral dimethyl acetamide doses of 1839 mg/kg during days 6 to 18 of gestation (RTECS 1987).

The signs and symptoms of oral exposure to this substance in humans include depression, lethargy, hallucinations, and jaundice (Proctor, Hughes, and Fischman 1988, p. 206). Patients given oral doses of 400 mg/kg daily showed depression, lethargy, confusion, and disorientation after 3 days (Weiss et al. 1962). Skin absorption is believed to have contributed substantially to the development of the jaundice seen in workers repeatedly exposed to a 20 to 25 ppm concentration of dimethyl acetamide (Johnson 1961, in ACGIH 1986, p. 205). According to the ACGIH, "the dermal factor is considered in practice to be so significant that no air concentration, however low, will provide protection if skin contact with dimethyl acetamide is permitted" (ACGIH 1986, p. 205).

Based on the evidence presented above, OSHA preliminarily concludes that, in the absence of a permissible exposure limit, workers in agriculture are at significant risk of experiencing the eye and skin irritation and liver damage associated with exposure to dimethyl acetamide. The Agency believes that the proposed 8-hour TWA PEL of 10 ppm, with a skin notation, is necessary to substantially reduce these significant risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

CAS: 123-91-1; Chemical Formula: O(CH,CH,)2O H.S. No. 1145

In construction and maritime, OSHA's PEL for dioxane is 100 ppm as an 8-hour TWA, with a skin notation. There is no PEL in agriculture. The ACGIH has an 8hour TLV®-TWA of 25 ppm for this substance, with a skin notation. NIOSH has a recommended exposure limit of 1 ppm as a 30-minute ceiling for dioxane

but concurs (Ex. 8-47, Table N6A) that the PEL being proposed by OSHA is appropriate. OSHA is proposing a 25ppm 8-hour TWA PEL for dioxane, with a skin notation, in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry.

Dioxane is a colorless liquid with an ethereal odor. It is an ingredient in fumigants, adhesives, cosmetics, deodorants, polishes, and emulsions. It is also used as a wetting and dispersing agent in textile processing, dye-baths, and stain and printing compositions (HSDB 1985). Dioxane also finds use as a solvent and a stabilizer in chlorinated solvents (HSDB 1985; Proctor, Hughes, and Fischman 1988, p. 219). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Dioxane is an irritant of the eyes, skin, and mucous membranes as well as a liver and kidney toxin and carcinogen in experimental animals. The oral LDso in rats is 4200 mg/kg, and the LCso in the same species is 46 g/m3 (approximately 13,000 ppm) for 2 hours (RTECS 1990). In rabbits, the median lethal dose by percutaneous absorption is 7600 mg/kg (RTECS 1990). Before death, acutely poisoned animals showed weakness, depression, incoordination, and coma (Clayton and Clayton 1982, p. 3947). Autopsy revealed histologic changes to the liver and kidneys of experimental animals (Clayton and Clayton 1982, p. 3948). Applied to the eyes of rabbits, dioxane caused mild, transient injury of the cornea, graded 4 on an ascending severity scale of 1 to 10 (Grant 1974, p. 417). The liquid causes irritation on repeated contact with the skin of rabbits; the degree of irritation is described as mild (Clayton and Clayton 1982, p. 3948; RTECS 1990). A 2-year drinking water study conducted by the Dow Chemical Company (1972b, as cited in ACGIH 1986/Ex. 1-3, p. 217), in which male and female rats were given water containing 1.0, 0.1, or 0.01 percent dioxane, showed that animals given the highest dose developed liver and nasal tumors, in addition to pathological changes in the liver and kidney. Rats in the 0.1-percent group showed renal tubular sloughing and hepatocellular degeneration but no significant increase in neoplasms. Because this study demonstrated hepato- and nephrotoxic effects at doses 10 times lower than the dose causing cancer in animals, the proposed permissible exposure limit reflects a level that will prevent dioxane's liver and kidney effects; this

level will also reduce carcinogenic effects. A study by Torkelson et al. (1974/Ex. 1–111) in four species of animals exposed to multiple daily airborne exposures of dioxane at 50 ppm showed no gross or histopathologic organ changes; this study demonstrates that the proposed 25-ppm level should protect against the risk of liver and kidney effects.

There is evidence in humans that dioxane is an irritant and a toxin to the liver and kidney. Human volunteers reported experiencing mild eye, nose, and upper respiratory tract irritation at dioxane vapor concentrations of 300 ppm for 15 minutes; when the concentration was increased to 1600 ppm for 10 minutes, the volunteers reported burning and tearing of the eyes (Proctor, Hughes, and Fischman 1988, p. 219). A 1-minute exposure to a 5500ppm concentration induced vertigo (Proctor, Hughes, and Fischman 1988, p. 219). Five fatalities occurred when humans were severely overexposed (concentration not specified) for a 5week period; before death, these individuals experienced stomach pain, vomiting, loss of appetite, scanty urine, anuria, and coma (Proctor, Hughes, and Fischman 1988, p. 220). Autopsy revealed liver and kidney damage and edema of the lungs and liver (Proctor, Hughes, and Fischman 1988, p. 220). Similar signs and symptoms were seen in another case that resulted in death: the individual involved is estimated to have been exposed for 1 week to concentrations ranging from 208 to 605 ppm (and perhaps higher) and to have had concurrent dermal exposure (Proctor, Hughes, and Fischman 1988, p. 220). A mortality study of workers exposed to dioxane at concentrations described as low was inconclusive in terms of dioxane's carcinogenicity in humans (IARC 1982, p. 121).

In the prior rulemaking, several commenters noted dioxane's carcinogenic potential in animals and urged OSHA to designate dioxane as a carcinogen (Exs. 8-47, Tr. 3-96, 3-97; Tr. 9-217, 9-218). OSHA is aware that the International Agency for Research on Cancer (IARC) has classified dioxane as a Group 2B (possible human) carcinogen based on its finding that the evidence of this substance's carcinogenicity in animals is sufficient to warrant this designation. As discussed earlier in this preamble, OSHA's use of a particular target organ classification for a substance is not meant to suggest that the chemical in question is without other adverse health effects. In the case of dioxane, for example, OSHA is aware that exposure causes sensory irritation.

liver damage, kidney damage, and the following cancers in experimental animals: liver adenomas and carcinomas in rats, hepatomas in guinea pigs, nasal cavity carcinomas in rats, and gall bladder carcinomas in guinea pigs (IARC 1982, p. 121). The classification of dioxane in the liver toxin section of this preamble is intended only to reflect the fact that the level of the proposed PEL, i.e., 25 ppm, is believed to be a level that will protect against dioxane's hepatotoxic effects.

Thus, OSHA preliminarily concludes that dioxane poses a significant risk of liver and kidney damage, and perhaps of cancer, to exposed workers. The Agency believes that an 8-hour TWA limit of 25 ppm for dioxane, with a skin notation, is necessary to protect workers in construction, maritime, and agriculture against these significant risks of material health impairment and that this limit will substantially reduce this significant risk. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. ETHYLENE DICHLORIDE CAS: 107-06-2; Chemical Formula:

ClCH₂CH₂Cl H.S. No. 1168

The OSHA PEL for ethylene dichloride (EDC) in construction and maritime is 50 ppm as an 8-hour TWA. In 1980, the ACGIH reduced its TLV* for ethylene dichloride to 10 ppm as an 8hour TWA. NIOSH has a recommended exposure limit (REL) of 1 ppm TWA and 2 ppm as a 15-minute ceiling limit and has designated EDC a potential human carcinogen. NIOSH also concurs (Ex. 8-47, Table N6A) with the limit being proposed. OSHA is proposing an 8-hour TWA limit of 1 ppm and a STEL of 2 ppm for ethylene dichloride in construction, maritime, and agriculture. These are the limits recently established for these substances in general industry.

Ethylene dichloride is a colorless liquid with a chloroform-like odor. EDC is registered in the United States for agricultural use as a post-harvest grain fumigant and a fumigant for use in orchards, agricultural premises, and mushroom houses (HSDB 1985). This substance also is used as a cleaner of leather and rubber goods and as a solvent, particularly in the metal cleaning industries (HSDB 1985). Its major uses are in the production of vinyl chloride and as an antiknock additive in gasolines (EPA 1987). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Ethylene dichloride causes narcosis in animals on acute exposure (EPA 1987) and has also been shown to cause mutations in bacterial test systems with microsomal activitation (EPA 1987; RTECS 1990). In contact with the skin of rabbits, liquid EDC causes mild irritation; in contact with the eye, this substance causes severe irritation (RTECS 1990). The oral LD50 in rats is 670 mg/kg, and the LC50 in the same species is 1000 ppm for 7 hours (RTECS 1990). The dermal LD50 in rabbits is 2800 mg/kg (RTECS 1990). Animals acutely poisoned by inhalation showed weakness, incoordination, restlessness, irregular breathing, and coma before death (EPA 1987). Dogs, monkeys, rabbits, rats, mice, and guinea pigs were exposed to varying concentrations of EDC for 7 hours/day, 5 days/week for 8 months; maximal no-effect levels were 400 ppm (dogs), 200 ppm (monkeys and rabbits), and 100 ppm (rats, mice, and guinea pigs) (Hayes 1982, p. 151). Other studies (Spencer et al. 1951; Hoffmann et al. 1971) have shown similar results.

Several studies indicate that the current OSHA PEL is insufficient to protect workers in construction, maritime, and agriculture against the toxic effects of exposure to EDC. A paper by Kozik (1957/Ex. 1-182) reported that workers generally exposed to ethylene dichloride at levels of 10 to 15 ppm but occasionally exposed to levels of 40 ppm experienced increased morbidity, diseases of the liver and bile ducts, and nervous system effects. Kozik investigated the effect of EDC on the speed of visual-motor reaction and on the number of errors made. There was no difference in reaction speed between the 17 gluers (exposed) and 10 machinists (control) before and after work. However, more errors were committed by the gluers (15 out of 17) than by controls (4 out of 10). These errors reflected disturbances of equilibrium and mobility of the nerve processes during a complicated reaction. Kozik also noted that, although the reaction errors had ceased by the beginning of the next working day in the machinists, they persisted in the gluers. The author also compared the muscular strength and endurance of the upper extremities in workers in the two groups. Both were decreased in the gluers, and both strength and endurance decreased with job longevity in these workers. The author attributed these distinct shifts in the functional state of the motor apparatus of the upper extremities to exposure to EDC. Eighty-three gluers were examined for diseases of the motor apparatus of the upper extremities. Neuromyalgia, myofasciculitis,

tendovaginitis, or angioneurosis was found in 67.7 percent of the subjects. Diseases of the liver and bile ducts were found in 19. The author concluded that "prolonged exposure to EDC vapors in concentrations close to the maximum permissible concentration or only slightly exceeding it causes pronounced alterations on the part of the liver and nervous system, which are typical of EDC poisoning." In addition, Brzozowski and associates (1954/Ex. 1–63) reported abnormal changes in the blood of 50 percent of workers (8 of 16) exposed to EDC levels of 10 ppm and above (Brzozowski, Czajka, Dutkiewicz et al. 1954/Ex. 1–63).

In the prior rulemaking, many commenters were of the opinion that a permissible exposure limit of 10 ppm, rather than the proposed 1-ppm limit, would provide adequate protection against EDC's hepatotoxic, central nervous system, and hematopoietic effects (Exs. 3-624, 3-677, 3-678, 3-741, 3-874, and 3-1174). In response to these commenters, OSHA noted [54 FR 2484-2485) that many studies report serious EDC-related effects among workers exposed to airborne concentrations in the 10- to 15-ppm range. For example, the aircraft workers in the Kozik (1957/ Ex. 1-182) study (average 8-hour TWA exposures of 10 to 15 ppm) experienced increased morbidity and lost more workdays than did non-EDC-exposed workers at the same factory. These workers experienced high rates of gastrointestinal disease and liver and gallbladder diseases; these symptoms and diseases are typical EDC exposure effects. Another study (Cetnarowicz 1959) examined refinery workers exposed to EDC at levels ranging from 10 to 200 ppm and found that these workers experienced many of the same symptoms as those experienced by the aircraft workers. Clinical analyses confirmed that the liver and gastrointestinal tract were the principal target organs affected by EDC exposure. Rosenbaum (1947) also reported that EDC exposures below 25 ppm (not further specified) caused functional nervous system disorders, including headache, insomnia, and fatigue, and also slowed the heartbeat rate in affected workers. In the general industry rulemaking, OSHA concluded that the evidence presented in these studies was consistent, biologically plausible, and convincing and noted that the symptoms and signs of EDC's effects had been confirmed both clinically (palpitation of enlarged livers, X-ray evidence of pyloric spasms) and by laboratory analysis (elevated urobilinogen levels,

positive Takata-Ara liver function tests, negative glucose tolerance tests).

In the earlier Air Contaminants rulemaking, there was considerable discussion of EDC's carcinogenicity, with some commenters (Exs. 3–677, 3–741, and 3–874) arguing that inhalation exposures to EDC in animals had not produced a statistically significant increase in tumors in exposed rats or mice. In response to these commenters, OSHA noted that NIOSH, EPA, and the International Agency for Research on Cancer (IARC) have all concluded that EDC is carcinogenic in animals. IARC summarized its findings as follows:

1,2-Dichloroethane [EDC] was tested in one experiment in mice and in one in rat by oral administration. In mice, it produced benign and malignant tumors of the lung and malignant lymphomas in animals of both sexes, hepatocellular cârcinomas in males and mammary and uterine adenocarcinomas in females. In rats, it produced carcinomas of the forestomach in male animals, benign and malignant mammary tumors in females, and hemangiosarcomas in animals of both sexes [IARC 1979, Vol. 20, p. 442].

These effects are severe, and evidence demonstrates that they occur at concentrations of about 10 ppm. A noeffect level has not been established for EDC. Accordingly, a substantial safety factor is appropriate and the 1 ppm level is necessary based on hepatotoxic effects alone; this limit provides, at most, a safety factor of 10. There is also evidence of EDC's carcinogenicity; however, OSHA is not regulating this substance on the basis of its carcinogenicity at this time. Nevertheless, carcinogenicity is an additional reason for promulgating a limit that is a factor of 10 below the lowest observed hepatotoxic effect

Based on this evidence, the Agency preliminarily concludes that an 8-hour TWA limit of 1 ppm and a 15-minute STEL of 2 ppm are necessary to protect workers in construction, maritime, and agriculture against the significant risks of liver damage, gastrointestinal toxicity, and cancer that are potentially associated with exposure to ethylene dichloride. OSHA believes that the proposed limits are necessary to substantially reduce these significant occupational risks. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors. HAFNIUM

CAS: 7440–58–6; Chemical Formula: Hf H.S. No. 2087

In general industry, construction, and maritime, OSHA's permissible exposure limit for hafnium is 0.5 mg/m³ as an 8-

hour TWA. There is no limit in agriculture. The ACGIH has a TLV*_TWA of 0.5 mg/m³ for this substance. NIOSH has no REL but concurs (Ex. 8–47, Table N3A) with the PEL being proposed. OSHA is proposing an 8-hour TWA PEL in agriculture of 0.5 mg/m³ for hafnium. Promulgation of this limit will make the PEL for hafnium consistent across all OSHA-regulated sectors.

Hafnium is a gray, ductile metal with a brilliant silver-like luster. It is used for control rods in water-cooled nuclear reactors and in light bulb filaments, electrodes, special glasses, and vacuum tubes (ACGIH 1986, p. 293; Hawley's 1987, p. 583).

Hafnium and its compounds are irritants of the eye and skin in humans and animals. Studies also indicate that hafnium and its compounds cause liver damage in animals (Haley 1962). The LD50 (route unreported) for hafnium in mice is 76 mg/kg (RTECS 1990). Rabbits showed transient eye irritation when 1 mg of hafnium chloride was placed into their eyes. In contact with unabraded skin, hafnium chloride caused transient edema and erythema in rabbits; application of this substance to abraded skin caused ulceration (Haley 1962). Rats fed hafnium in the diet at a 1 percent level showed slight changes in the liver at autopsy (Chemical Safety Data Sheet 1966, in Proctor, Hughes, and Fischman 1988, p. 267). There are no data on the toxicity of hafnium in humans.

Based on this evidence in animals, OSHA preliminarily concludes that hafnium and its compounds potentially cause eye and skin irritation and liver damage. OSHA believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these effects. The Agency believes that establishing an 8-hour TWA limit of 0.5 mg/m3 will substantially reduce these risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. HEXACHLORONAPHTHALENE CAS: 1335-87-1; Chemical Formula: C10H2Cls

H.S. No. 2089

In general industry, construction, and maritime, OSHA currently has an 8-hour TWA limit for hexachloronaphthalene of 0.2 mg/m³, with a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. OSHA has no PEL for hexachloronaphthalene in agriculture. The ACGIH's current TLV*-TWA for this substance is 0.2 mg/m³,

with a skin notation. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the PEL being proposed. OSHA is proposing a TWA PEL of 0.2 mg/m³, with a skin notation, for hexachloronaphthalene in agriculture. Promulgation of this limit will make the PEL for hexachloronaphthalene consistent across all OSHA-regulated sectors.

Hexachloronaphthalene is a light yellow or white waxy solid with an aromatic odor. In commercial use, the chloronaphthalenes occur as mixtures of naphthalenes having varying degrees of chlorination. Hexachloronaphthalene is used in flameproofing and waterproofing; to insulate electrical equipment; and as a lubricant additive (ACGIH 1986, p. 302; Hazardous Substance Fact Sheet 1985, p. 1).

Hexachloronaphthalene causes liver damage and a severe form of dermatitis called chloracne (Proctor, Hughes, and Fischman 1988, p. 270). In rats, repeated exposure to an average concentration of 8.9 mg/m3 of a penta- and hexachloronaphthalene mixture resulted in poor growth, jaundice, and death. There was marked fatty degeneration and centrilobular necrosis of the liver at autopsy. Minor liver injury also occurred at repeated exposures to a concentration of 1.16 mg/m3 (Irish 1963, in Clayton and Clayton 1982, p. 3670-3671). Rabbits intraperitoneally injected with a 15 mg/day dose of a penta- and hexachloronaphthalene mixture for 12 to 26 days developed liver disease (HSDB 1985).

Acute yellow atrophy of the liver has been reported in workers repeatedly exposed to a mixture of penta- and hexachloronaphthalene at concentrations averaging 1 to 2 mg/m³. These workers also experienced symptoms of nausea, indigestion, weight loss, and jaundice (Hygienic Guide Series 1966; Elkins 1959). Long-term skin contact with the fume, dust, or hot vapor of the higher chlorinated naphthalenes causes chloracne, which is slow to develop and may take months to disappear (Irish 1963, in Clayton and Clayton 1982, p. 3672–3673).

Based on this evidence in humans and animals, OSHA preliminary concludes that exposure to hexachloronaphthalene causes chloracne and liver damage and that, in the absence of a limit, workers in agriculture are at risk of experiencing these adverse health effects. The Agency believes that the proposed 8-hour TWA limit of 0.2 mg/m³, and a skin notation, are necessary to substantially reduce these significant risks of material health impairment. In addition, promulgation of this limit will make

OSHA's PEL for this substance consistent across all regulated sectors. HYDRAZINE CAS: 302-01-2; Chemical Formula: H₂N-NH₂ H.S. No. 1205

In construction and maritime, OSHA's current limit for hydrazine is 1ppm as an 8-hour TWA, with a skin notation. There is no limit in agriculture. OSHA is retaining the skin notation and proposing an 8-hour TWA PEL of 0.1 ppm for hydrazine in construction, maritime, and agriculture. Because of hydrazine's potential carcinogenic hazard, NIOSH (1978e/Ex. 1-263; Ex. 8-47) recommends that workplace exposures not exceed 0.03 ppm, as measured over 2 hours; this level represents the lowest detectable concentration over this sampling interval. The 1987-88 ACGIH TLV® for hydrazine is 0.1 ppm as an 8-hour TWA. with a skin notation, and the ACGIH also designates this substance a potential human carcinogen. Promulgation of the proposed limit will make the PEL for hydrazine consistent across all regulated sectors.

Hydrazine is an odorless, fuming, oily liquid with an ammonia-like odor. Hydrazine is used as a high-energy rocket fuel, a reducing agent, an oxygen scavenger for boiler waters, and a chemical intermediate (ACGIH 1986, p. 310(89)). It is also used in the preparation of agricultural chemicals and pharmaceuticals (Hawley's 1987, p. 612).

Hydrazine has many toxic effects in humans and experimental animals. Humans exposed to hydrazine vapors experience immediate irritation of the nose and upper respiratory tract as well as nausea and dizziness (Proctor, Hughes, and Fischman 1988, p. 273). Severe overexposure causes a temporary blindness that may persist for 24 hours. In contact with the skin or eyes, liquid hydrazine causes severe burns (Proctor, Hughes, and Fischman 1988, p. 273). Skin sensitization has also been reported in humans (ACGIH 1986, p. 310.1(89)). Hydrazine has been absorbed through the skin in humans to cause systemic effects, manifested as weakness, tremor, and vomiting; in one fatal case of occupational overexposure, nephritis and liver damage were seen at autopsy (Proctor, Hughes, and Fischman 1988, p. 273).

In experimental animals, hydrazine causes moderate to severe irritation of the eyes, skin, and mucous membranes, induces convulsions, produces hemolysis, damages the liver, and causes cancer (ACGIH 1986, pp. 310(89), 310.1(89); RTECS 1990; Proctor, Hughes,

and Fischman 1988, p. 272). The oral LD50 in rats is 60 mg/kg, and the LC50 in the same species is 570 ppm for 4 hours (RTECS 1990). The dermal LDso in rabbits is 91 mg/kg (RTECS 1990). Animals acutely poisoned by dermal absorption show fatty degeneration of the liver, anemia, destruction of erythrocytes, loss of appetite, weakness. vomiting, convulsions, and weakness (ACGIH 1986, p. 310(89)). Lethal exposures by inhalation cause pathological changes in the liver. kidneys, and lungs that are visible at autopsy (ACGIH 1986, p. 310(89)). A hepatotoxic response in mice, anemia and weight loss in dogs, and a doserelated depression in growth rate in rats occurred after a 6-month exposure to 1 ppm of hydrazine for 6 hours per day, 5 days per week, or to a 0.2-ppm concentration continuously (Haun and Kinkead 1973/Ex. 1-824).

The ACGIH has assigned an A2 designation (suspected human carcinogen) to hydrazine, based on a study by MacEwen, Vernot, and Haun (1979/Ex. 1-193) showing significant increases in nasal tumors in rats exposed to 1 or 5 ppm hydrazine, in thyroid adenocarcinomas in rats exposed to 5 ppm, and in lung adenomas among mice exposed to 1 ppm. NIOSH also considers hydrazine a potential human carcinogen (Ex. 8-47, Table N6B), as does the International Agency for Research on Cancer [IARC 1987, p. 224]. The animal studies conducted by Haun and Kinkead (1973/Ex. 1-824) and by MacEwen, Vernot, and Haun (1979/Ex. 1-193) clearly demonstrate that exposure to hydrazine at the current 1ppm PEL presents a significant risk of liver disease, respiratory cancer, and adverse blood effects; animals exposed to airborne concentrations at this level have exhibited all of these responses.

In the prior rulemaking, some commenters (Exs. 8–16, 194; Tr. 9–218; Tr. 3–309) questioned the classification of hydrazine in the liver target organ section of the preamble, believing that it should be placed in the cancer section instead. However, as discussed elsewhere in this preamble, OSHA does not intend this classification scheme to have regulatory implications and has adopted it only to facilitate generic rulemaking.

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 0.1 ppm, with a skin notation, for hydrazine. OSHA preliminarily concludes that this limit will substantially reduce the significant risks of liver disease, cancer, and hematopoietic effects that have been demonstrated to occur in animals at exposures above the proposed PEL.

All of these effects clearly constitute material health impairments, and OSHA believes that the proposed PEL will substantially reduce this significant risk. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

METHYLCYCLOHEXANOL CAS: 25639-42-3; Chemical Formula: CH₃C₆H₁₀OH H.S. No. 1269

In construction and maritime, OSHA currently has an 8-hour TWA limit of 100 ppm for methylcyclohexanol. There is no PEL in agriculture. The Agency is proposing an 8-hour TWA of 50 ppm as the PEL for this substance in construction, maritime, and agriculture; this is the 1987–1988 ACGIH TLV® for methylcyclohexanol. NIOSH has no REL for this substance but concurs (Ex. 8–47, Table N1) with OSHA's proposed limits for methylcyclohexanol. This is the limit recently established for this substance in general industry.

Methylcyclohexanol is a colorless, viscous liquid with an aromatic odor; in industrial use, it takes the form of a mixture of isomers in which the meta and para forms predominate.

Methylcyclohexanol finds use as a degreasing agent, a solvent for esters and ethers, a blending agent for soaps and detergent, and a solvent for gums, oils, resins, and waxes (ACGIH 1986, p. 385; Clayton and Clayton 1982, p. 4650). It is also an ingredient in soap-based spot removers and a chemical intermediate for lubricating oil additives (HSDB 1985).

In addition to liver injury, exposure to methylcyclohexanol causes eye, nose, and mucous membrane irritation and, at high concentrations, narcosis (Proctor, Hughes, and Fischman 1988, p. 338). The oral LDso in rats is 1660 mg/kg (RTECS 1988). The median lethal dose in rabbits by dermal application is 6.8 to 9.4 g/kg (Clayton and Clayton 1982, p. 4651). Animals acutely poisoned via dermal exposure showed tremors, hypothermia, and narcosis (Clayton and Clayton 1982, p. 4651). The vapor causes signs of irritation in rabbits at concentrations of approximately 500 ppm (Grant 1986, p. 614). Repeated inhalation exposures to the vapor caused salivation, eye irritation, and lethargy in rabbits exposed to a 500-ppm concentration, but exposures to 230 ppm caused no observable effects. Fifty 6-hour exposures to a concentration of 120 ppm caused microscopic changes in the liver and kidney tissue of rabbits that were visible at autopsy (Treon, Crutchfield, and Kitzmiller 1943b/Ex. 1-394).

In humans, headaches and eye and respiratory irritation have been reported after prolonged exposures to high (not further specified) concentrations of methylcyclohexanol (Fillipi 1914, as cited in ACGIH 1986/Ex. 1–3, p. 385). Several workers exposed to a solvent that contained methylcyclohexanol at unspecified concentrations had a significantly reduced number of leukocytes and one worker had slight lymphocytosis (Clayton and Clayton 1982, p. 4652).

Based on this evidence of methylcyclohexanol's toxicity in humans and animals, OSHA is proposing an 8-hour TWA limit of 50 ppm for this substance in construction. maritime, and agriculture. OSHA preliminarily concludes that this limit will protect workers in these sectors against the significant risks of hepatic and renal damage and narcosis that are associated with exposures to this substance at concentrations above the proposed PEL. The Agency believes that the proposed limit will substantially reduce these risks. In addition. promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. NITROETHANE

CAS: 79-24-3; Chemical Formula: CH₂CH₂NO₂

H.S. No. 2118

The OSHA PEL for nitroethane in general industry, construction, and maritime is 100 ppm as an 8-hour TWA. There is no limit in agriculture for nitroethane. The ACGIH has a TLV*–TWA of 100 ppm for this substance. NIOSH has no REL but concurs (Ex. 8–47, Table N3A) with the limit being proposed. The Agency is proposing an 8-hour TWA limit of 100 ppm for nitroethane in agriculture. Promulgation of this limit will make the PEL for nitroethane consistent across all OSHA-regulated sectors.

Nitroethane is a colorless, oily liquid with a faint chloroform-like, fruity odor (ACGIH 1986, p. 434; HSDB 1985). Nitroethane is used as a solvent, a fuel additive, an intermediate in chemical synthesis, and in propellant research (Hawley's 1987, p. 828; ACGIH 1986, p.

Nitroethane is an irritant of the eyes and mucous membranes in both animals and humans; in animals, it is a hepatotoxin and, at high concentrations, a narcotic. The oral LD₅₀ in rats is 1100 mg/kg, and the LC₅₀ in mice is 19,500 mg/m³ for 2 hours (RTECS 1987). Death occurred in rabbits exposed to 5000 ppm nitroethane for a period of 3 hours. Rabbits exposed to half of that concentration (2500 ppm) for the same

duration survived. Exposure to nitroethane concentrations above 5000 ppm caused irritation of the eyes and mucous membranes, labored breathing, pulmonary rales, and, in some rabbits, pulmonary edema. Some animals also exhibited brief convulsions. Mild to severe liver damage and some kidney damage was observed at autopsy in animals exposed to lethal concentrations of nitroethane (Machle, Scott, and Treon 1940; AIHA 1978). Exposure of monkeys and various laboratory animal species to a 500-ppm concentration of nitroethane caused no observable effects (Mackle, Scott, and Treon 1940).

Toxicity data on humans exposed to nitroethane are limited. Nitroethane is reported to cause irritation of the eyes and mucous membranes (Merck 1983, p. 857). There are no reports of chronic effects in humans but, based on effects seen in animals, exposure to high concentrations may cause liver damage. Prolonged skin contact with nitroethane causes irritation and dermatitis (Proctor, Hughes, and Fischman 1988, p. 372).

Based on this evidence, OSHA is proposing a 100 ppm 8-hour TWA limit to protect workers in agriculture from the significant risks of irritation and liver damage caused by exposure to higher concentrations of nitroethane. The Agency preliminarily concludes that this limit is necessary to substantially reduce a significant risk of material health impairment in exposed workers. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all-regulated sectors.

NITROGEN TRIFLUORIDE CAS: 7783-54-2; Chemical Formula: NF₃ H.S. No. 2119

In general industry, construction, and maritime, OSHA's permissible exposure limit for nitrogen trifluoride is 10 ppm as an 8-hour TWA. There is no limit for this substance in agriculture. The ACGIH has an 8-hour TLV*-TWA of 10 ppm for nitrogen trifluoride; NIOSH has no REL but concurs with the limit being proposed (Ex. 8-47, Table N3A). OSHA proposes to establish an 8-hour TWA limit of 10 ppm for this substance in agriculture. Promulgation of this limit will make the PEL for nitrogen trifluoride consistent across all OSHA-regulated sectors.

Nitrogen trifluoride is a colorless gas with a moldy odor. This substance is used as an oxidizer for high energy fuels, in the preparation of tetrafluorohydrazine, and in the fluorination of fluorocarbon olefins (ACGIH 1986, p. 437; Braker and Mossman 1980, p. 538).

Acute exposure to nitrogen trifluoride causes methemoglobinemia, and chronic exposure causes kidney and liver injury. The 1-hour LCsos in rats and monkeys are 6700 ppm and 7500 ppm, respectively (RTECS 1987). Rats exposed to a 10,000ppm concentration of nitrogen trifluoride for 60 to 70 minutes died; methemoglobin levels had reached 60 to 70 percent (Dost, Reed, and Wang 1970). Acutely poisoned animals showed the following signs and symptoms: severe respiratory distress, cyanosis, incoordination, collapse, and convulsions (Torkelson et al. 1962). Dogs exposed to a 9600-ppm concentration of nitrogen trifluoride for 60 minutes showed Heinz body anemia; reduced hematocrit, hemoglobin, and red blood cell counts; and signs of anoxia (Vernot, Haun, MacEwen, and Egan 1973). Rabbits given nine intraperitoneal injections of nitrogen trifluoride showed grossly enlarged spleens, liver damage, and myocardial degeneration at autopsy (ACGIH 1986, p. 437). Autopsy showed mild to moderate liver and kidney changes in rats exposed to a 100-ppm concentration of nitrogen trifluoride for 7 hours/day for 4.5 months; no hematologic changes were seen in these subchronically exposed animals (Torkelson et al. 1962).

There are no reported cases of industrial poisoning with nitrogen trifluoride.

Based on this evidence, OSHA preliminarily concludes that nitrogen trifluoride causes methemoglobinemia and may cause liver and kidney injury in exposed workers. The Agency believes that the proposed limit is necessary to reduce the significant risk posed to agriculture workers exposed to this substance. OSHA believes that establishing an 8-hour TWA limit of 10 ppm is necessary to substantially reduce the risk that agricultural workers will experience these material health impairments. Promulgation of the proposed limit will make the PEL for nitrogen trifluoride consistent across all OSHA-regulated sectors.

OCTACHLORONAPHTHALENE CAS: 2234-13-1; Chemical Formula: C10Cla

H.S. No. 1295

In construction and maritime, OSHA currently has an 8-hour TWA limit of 0.1 mg/m³, with a skin notation, for octachloronaphthalene. There is no PEL in agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) that these limits are appropriate. The 1987-1988 ACGIH TLV®s for octachloronaphthalene are 0.1 mg/m3

and 0.3 mg/m3 as 8-hour TWA and 15minute STEL limits, respectively. In construction and maritime, the Agency is retaining the 8-hour TWA limit and the skin notation and is proposing to add a STEL of 0.3 mg/m3 for this substance. OSHA is also proposing to extend both limits to agriculture. Promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

Octachloronaphthalene is a nonflammable, pale vellow, waxy solid that contains 70 percent chlorine. The chlorinated naphthalenes are highly toxic to the liver by several routes of administration: ingestion, inhalation, and percutaneous absorption (Clayton and Clayton 1982, p. 3670). The liver damage caused by these substances is termed acute yellow atrophy, and there is general agreement that the toxicity of the naphthalenes increases with the compound's degree of chlorination (Sikes, Wise, and Bridges 1952, Ex. 1-804; Clayton and Clayton 1982, p. 3671). In animals, exposure to the chloronaphthalenes causes acne-like lesions that itch severely (Patty 1963g/ Ex. 1-845), and human volunteers exposed dermally to the penta- and hexachloronaphthalenes also showed this response (Proctor, Hughes, and Fischman 1988, p. 384). However, human volunteers exposed dermally to octachloronaphthalene failed to develop acne (Proctor, Hughes, and Fischman 1988, p. 384). Several deaths and many nonfatal cases of liver disease have been reported in workers occupationally exposed to the heated vapors of chlorinated naphthalene (specific chloronaphthalene compound not identified) (AIHA 1966).

Based on this evidence, OSHA is retaining the 8-hour TWA PEL of 0.1 mg/ m3 and the skin notation and is proposing to add a STEL of 0.3 mg/m3 for octachloronaphthalene in construction and maritime; the Agency is also proposing to extend both limits to agriculture. The Agency preliminarily concludes that the TWA and STEL limits are necessary to protect workers in construction, maritime, and agriculture against the significant risks of serious liver damage associated with exposure to this substance. OSHA considers liver damage a material health impairment. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

PENTACHLORONAPHTHALENE CAS: 1321-64-8; Chemical Formula: C10H3Cls

H.S. No. 2123

OSHA's permissible exposure limit for pentachloronaphthalene in general industry, construction, and maritime is 0.5 mg/m3 as an 8-hour TWA; this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. There is no limit in agriculture. The ACGIH has a TLV*-TWA limit of 0.5 mg/m3 for pentachloronaphthalene. NIOSH has no REL but concurs with the limit being proposed (Ex. 8-47, Table N3A). OSHA is proposing to establish a TWA PEL of 0.5 mg/m3, with a skin notation, for pentachloronaphthalene in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Pentachloronaphthalene is a pale yellow solid with an aromatic odor similar to that of mothballs. Pentachloronaphthalene is used in synthetic waxes and electrical insulating materials, as a lubricant, and as a coating for wood, paper, and textiles (Hazardous Substance Fact Sheet 1986, p. 1; HSDB 1984). The chloronaphthalenes are used in commercial products as mixtures of naphthalenes of varying degrees of chlorination; the penta-, hexa-, hepta-, and octachloronaphthalenes are considered more toxic than the mono- or trichloronaphthalenes.

Pentachloronaphthalene causes chloracne and liver damage in humans and animals. When this substance was applied to rabbit skin, the skin underwent epithelial hyperplasia, inflammatory and degenerative changes, and, finally, regenerative processes (Adams et al. 1941, in Clayton and Clayton 1981, p. 3671). Rats fed a mixture of penta- and hexachloronaphthalene at a rate of 3 g/ day for 1 month showed weight loss, severe liver injury, and were sick; nine out of 10 of the animals died (Drinker et al. 1937, in Clayton and Clayton 1981, p. 3670). Exposure to the vapors of a pentaand hexachloronaphthalene mixture at an average concentration of 1.16 mg/m3 caused liver injury in rats; at 8.88 mg/ m3, there was poor growth, severe liver injury, and death (Irish 1963).

In humans, exposure to chlorinated naphthalenes containing pentachloronaphthalene as the major constituent has caused numerous cases of chloracne and many cases of liver damage; several of these cases have been fatal (ACGIH 1986, p. 460). Nine reports of toxic hepatitis as a result of exposure to chlorinated naphthalenes were reported by von Oettingen (von Oettingen 1955). Pentachlorinated naphthalenes were also reported to be

the cause of seven cases of toxic hepatitis, two of them fatal (Cotter 1944, in ACGIH 1986, p. 460). Workers handling chlorinated naphthalenes have developed chloracne; both long-term contact with the material or short-term contact with its hot vapors can cause chloracne (Irish 1963). Chloracne is characterized by papules, large comedones and pustules, mainly on the face, neck, arms, and legs. Symptoms, including headache, vertigo, anorexia, and systemic effects, often accompany the chloracne-related skin lesions (Kleinfeld et al. 1972; Greenberg et al. 1939).

Based on this evidence in humans and animals, OSHA preliminarily concludes that pentachloronaphthalene causes skin and liver damage in exposed individuals. In the absence of a limit for this substance, OSHA believes that workers in agriculture are at significant risk of experiencing these adverse effects. OSHA believes that establishing a PEL of 0.5 mg/m3 as an 8-hour TWA. and a skin notation, for pentachloronaphthalene is necessary to substantially reduce these risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. PROPYLENE DICHLORIDE

CH₃CHCICH₂Cl
H.S. No. 1341
OSHA's limit for propylene dichloride in construction and maritime is 75 ppm as an 8-hour TWA. The 1987–1988
ACGIH TLV*s for propylene dichloride are 75 ppm (8-hour TWA) and 110 ppm (15-minute STEL). NIOSH has no REL for this substance. In construction and

CAS: 78-87-5; Chemical Formula:

for this substance. In construction and maritime, OSHA is retaining an 8-hour TWA of 75 ppm and proposing to add a STEL of 110 ppm. The Agency is also proposing to extend both limits to agriculture. These are the limits recently established for this substance in general

industry.

Propylene dichloride is a colorless, flammable, mobile liquid with an odor like that of chloroform. Propylene dichloride (also called 1,2dichloropropane) is an ingredient of soil fumigants, and a solvent for oils, fats, drycleaning, and metal degreasing (EPA 1987). It is also a chemical intermediate, a scavenging agent for gasoline, and an insecticide for fruits, grains, and livestock (ACGIH 1986, p. 501). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

The primary hazards associated with exposure to propylene dichloride are inhalation-induced toxicity to liver tissue, central nervous system depression, and skin and eye irritation. The oral LDse in rats is 1947 mg/kg, and the LC50 in the same species is 14 g/m3 for 8 hours (RTECS 1990). The dermal LDso in rabbits is 8750 mg/kg (RTECS 1990). Repeated inhalation exposures to 1000 ppm have been reported to kill dogs (after 24 exposures), guinea pigs (after 22 exposures), and rats (in some cases after only seven exposures); however, some animals survived more than 100 seven-hour exposures. Necropsy showed severe liver damage; the hepatotoxicity of propylene dichloride appears to be greater than that of carbon tetrachloride and less than that of ethylene dichloride (Heppel, Neal, Highman, and Porterfield 1946/Ex. 1-510). Animals of these same species (rats, dogs, and guinea pigs) survived 128 to 140 7-hour exposures to 400 ppm propylene dichloride for 5 days/week without histologic effects, while mice died from similar exposures; surviving mice displayed hepatomas (Heppel, Highman, and Peake 1948/Ex. 1-605). The National Toxicology Program recently completed a carcinogenicity bioassay in mice and rats (NTP 1986c). In male and female mice, a statistically significant and dose-related increase in hepatocellular tumors was seen (IARC 1986, p. 140). The results were inconclusive in female rats and negative in male rats (IARC 1986, p. 140). Based on this evidence, the International Agency for Research on Cancer concluded that there was limited evidence that propylene dichloride is carcinogenic in animals (IARC 1986, p. 140).

Workers inhaling high levels (not further specified) of propylene dichloride showed signs of severe liver damage, hemolytic anemia, and developed acute kidney failure; in these three cases, the onset of symptoms was delayed for more than 24 hours (Proctor, Hughes, and Fischman 1988, p. 424). Short-term exposures to 400- or 500-ppm concentrations caused no apparent effects in workers (Proctor, Hughes, and Fischman 1988, p. 424). In repeated or prolonged contact with the skin. propylene dichloride causes defatting and may lead to dermatitis (Proctor, Hughes, and Fischman 1988, p. 424). Propylene dichloride accidentally sprayed into the eye of a worker caused transient corneal damage (Grant 1986, p.

328).

Because of propylene dichloride's toxicity in humans and animals, OSHA is retaining the 8-hour TWA PEL of 75 ppm, proposing to add a 15-minute STEL of 110 ppm in construction and maritime. and proposing to extend both limits to agriculture. The Agency preliminarily concludes that this combined limit will protect workers in construction. maritime, and agriculture against the significant risks of sensory irritation, hepatotoxic effects, central nervous system depression, and cancer potentially associated with exposures to this substance. OSHA believes that the TWA and STEL will reduce this risk substantially. In addition, premulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

1,1,2,2-TETRACHLOROETHANE CAS: 79-34-5; Chemical Formula: CHCl₂CHCl₂

H.S. No. 1385

In construction and maritime, OSHA's PEL for 1.1,2,2-tetrachloroethane is 5 ppm as an 8-hour TWA, with a skin notation. The 1987-1988 ACGIH TLV* for this substance is 1 ppm as an 8-hour TWA, with a skin notation. NIOSH considers 1,1,2,2-tetrachloroethane a potential human carcinogen but concurs (Ex. 8-47, Table N6A) with the limit being proposed. OSHA is proposing a PEL of 1 ppm as an 8-hour TWA limit, with a skin notation, for tetrachloroethane in construction. maritime, and agriculture. This is the limit recently established for this substance in general industry.

1,1,2,2-Tetrachloroethane (also called acetylene tetrachloride) is a colorless, nonflammable, heavy, mobile liquid with a sweet, chloroform-like odor. This substance is used as a chemical intermediate, a solvent, and an insecticide (IARC 1979, p. 479). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

1,1,2,2-Tetrachloroethane is toxic both by inhalation and skin absorption (Proctor, Hughes, and Fischman 1988, p. 460). In addition to liver damage, exposure to this substance causes kidney damage and central nervous system depression (Clayton and Clayton 1981, p. 3514). The oral LDso in rats is 800 mg/kg, and the lowest lethal concentration in the same species is 1000 ppm for 4 hours (RTECS 1990). The dermal LDso in rabbits is 6.4 g/kg (Clayton and Clayton 1981, p. 3514). Rats survived a 4-hour exposure to a 500-ppm concentration but died when the concentration was increased to 1000 ppm for the same interval (Clayton and Clayton 1981, p. 3514). Rabbits exposed to a 14.6-ppm concentration for 3 to 4

hours daily for 7 to 11 months showed mild liver damage (Clayton and Clayton 1981, p. 3515). In monkeys exposed to 1000 or 4000 ppm for 2 hours/day for 190 days, marked vacuolation of the liver was seen at autopsy (HSDB 1989). 1,1,2,2-Tetrachloroethane has been tested in carcinogenicity bioassays in mice and rats. In mice of both sexes, this substance caused a significant increase in the incidence of hepatocellular carcinomas; in rats, however, no significant increase was seen (IARC 1987, p. 354).

Workers acutely overexposed to 1,1,2,2-tetrachloroethane on the job have died after experiencing nausea, vomiting, abdominal pain, jaundice, tenderness in the area of the liver, delirium, convulsions, and coma (Proctor, Hughes, and Fischman 1988, p. 460). Two men exposed to 116 ppm for 20 minutes reported dizziness and vomited; when the concentration was increased to 146 ppm, they became dizzy after 10 minutes, experienced mucous membrane irritation after 12 minutes, and reported fatigue after 20 minutes (Proctor, Hughes, and Fischman 1988, p. 460). Occupational exposures to 1,1,2,2tetrachloroethane at concentrations ranging from 20 to 65 ppm caused nausea, vomiting, abdominal pain, and tremor (Proctor, Hughes, and Fischman 1988, p. 460).

Based on this evidence, OSHA
preliminarily concludes that the exposed
workers in construction, maritime, and
agriculture are at risk of experiencing
the hepatotoxic effects of exposure to
1.1.2.2-tetrachloroethane. OSHA
preliminarily finds that the proposed 1
ppm 8-hour TWA limit and skin notation
are necessary to substantially reduce
this significant risk. In addition,
promulgation of this limit will make
OSHA's PEL for this substance
consistent across all regulated sectors.
TETRACHLORONAPHTHALENE
CAS: 1335–88-2; Chemical Formula:

C₁₀H₄Cl₄ H.S. No.: 2155

OSHA's limit for tetrachloronaphthalene in general industry, construction, and maritime is an 8-hour TWA of 2 mg/m3, with a skin notation. There is no limit for this substance in agriculture. The ACGIH TLV*-TWA for tetrachloronaphthalene is 2 mg/m3; NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 2 mg/ m3, and a skin notation, for tetrachloronaphthalene in agriculture; adoption of this limit would make the PEL for this substance consistent across all OSHA-regulated industries.

Tetrachloronaphthalene is a colorless to pale yellow solid with an aromatic odor (ACGIH 1986, p. 562). The chloronaphthalenes in commercial use are synthetic waxes and lubricants that are composed of varying mixtures of the tri-, tetra-, penta-, or hexachloronaphthalenes. Chloronaphthalenes are used as electrical insulators, condenser dielectrics, and separators in batteries. They also find use in flame- and waterproof coatings for wood, paper, and textiles and were formerly used in pesticides (HSDB 1989). In agriculture, chloronaphthalenes have been used as lubricants for feed pelleting and other farm machinery (Clayton and Clayton 1981, p. 3671).

Tetrachloronaphthalene causes liver damage in humans and animals. There are no acute toxicity data for tetrachloronaphthalene alone. Some animals in a group of rats fed 0.5 mg/kg/ day of a mixture of tetra- and pentachloronaphthalene for 2 months became sick and others died; at autopsy, signs of liver injury were apparent (Drinker et al., in Clayton and Clayton 1981, p. 3670). Rats exposed for 16 hours/day by inhalation to a 1.3-mg/m3 concentration of tri- and tetrachloronaphthalene for up to 4.5 months showed no adverse effects other than possible liver enlargement; at a concentration of 19.97 mg/m3, however, liver damage was seen in these animals at autopsy (Drinker et al., in Clayton and Clayton 1981, p. 3670). Thousands of farm animals have been killed by hyperkeratosis, a disease caused by the ingestion of chloronaphthalenecontaining lubricants that have contaminated pelleted feed (Gosselin, Smith, and Hodge 1984, p. II-172).

Workers exposed to chloronaphthalenes by inhalation of the vapor or dust have developed toxic hepatitis and necrosis of the liver: several deaths have been attributed to the industrial use of the chloronaphthalenes (Drinker et al. 1937; Greenburg, Mayers, and Smith 1937; Mayers and Smith 1942). Workers exposed for 4 months to an unknown concentration of tetra- and pentachloronaphthalene developed headaches, fatigue, anorexia, and vertigo; the dermatitis and chloracne developed by these workers, however, appears to have been caused by penta-, rather than tetra-, chloronaphthalene (Kleinfeld, Messite, and Swencicki 1972). Tests involving human volunteers have shown that the tri- and tetrachloronaphthalenes do not cause chloracne when in contact with the skin (Shelley and Kligman 1957).

Based on this evidence in humans and animals, OSHA preliminarily concludes that tetrachloronaphthalene is a liver toxin that poses a potentially significant risk to workers in agriculture.

Accordingly, OSHA is proposing to extend the Agency's 2-mg/m³ 8-hour TWA PEL and a skin notation to workplaces in this sector; this action will provide agricultural workers with the same protection afforded workers in other OSHA-regulated sectors.

TRICHLORONAPHTHALENE
CAS: 1321-65-9; Chemical Formula:
C10HsCls

H.S. No. 2163

OSHA's limit for trichloronaphthalene in general industry, construction, and maritime is 5 mg/m³ as an 8-hour TWA, with a skin notation. There is no limit in agriculture. The ACGIH TLV*-TWA for this substance is 5 mg/m³, with a skin notation. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 5 mg/m³, and a skin notation, for trichloronaphthalene in agriculture; this action would make OSHA's limit for this substance consistent across all OSHA-regulated sectors.

Trichloronaphthalene is a colorless, white, or pale yellow solid with an aromatic odor (ACGIH 1986, p. 600). The chloronaphthalenes in commercial use are synthetic waxes and lubricants that are composed of varying mixtures of the tri- and tetra-, or penta- and hexa-, chloronaphthalenes. Chloronaphthalenes are used in insulation for electric wires, as additives for lubricants, as supports for storage batteries, and in coatings for foundry use. These substances are also used in solvents and as immersion liquids in microscopy (HSDB 1989).

Trichloronaphthalene is a liver toxin in humans and animals. There are no acute toxicity data for trichloronaphthalene alone. Some of a group of rats fed a mixture of tetra- and trichloronaphthalene at a dose of 0.5 mg/kg/day for 2 months died, while others became sick; at autopsy, all animals showed signs of liver damage (Drinker et al. 1957). Daily exposure of rats to the vapors of a mixture of tetraand trichloronaphthalene at a concentration of 1.3 mg/m3 for as long as 4.5 months produced only slight enlargement of the liver; increasing the concentration to 10.97 mg/m3, however, resulted in liver damage visible at autopsy (Drinker et al. 1957). Thousands of farm animals died after ingesting chloronaphthalene-contaminated feed; the feed was contaminated by the

lubricants used to oil the feed-pelleting machinery (Gosselin, Smith, and Hodge

1984, p. II-172).

A worker exposed to a 3-mg/m3 concentration of trichloronaphthalene (mixed with tetrachloronaphthalene) developed toxic hepatitis but subsequently recovered (Mayers and Smith 1942, in ACGIH 1986, p. 600). No industrial fatalities have been attributed to trichloronaphthalene exposure (ACGIH 1986, p. 600). Although the specific threshold for trichloronaphthalene-induced eye irritation is not known, this substance is regarded as an eye irritant (Parmeggiani 1983, p. 466). Tests in human volunteers have shown trichloronaphthalene not to be acnegenic, although some of the chloronaphthalenes do cause chloracne (Shelley and Kligman 1957)

Based on this evidence in humans and animals, OSHA preliminarily concludes that trichloronaphthalene is a liver toxin that poses a potentially significant risk to workers in agriculture. Accordingly, OSHA is proposing to extend the Agency's 5 mg/m³ 8-hour TWA PEL, and a skin notation, to workplaces in this sector; this action will provide agricultural workers with the same protection provided to workers in other

OSHA-regulated sectors.

1,2,3-TRICHLOROPROPANE CAS: 96–18–4; Chemical Formula:

CH2CICHCICH2CI H.S. No. 1407

In construction and maritime, OSHA's PEL for 1,2,3-trichloropropane is 50 ppm as an 8-hour TWA. There is no PEL in agriculture. The 1987–1988 ACGIH TLV* is 10-ppm TWA, with a skin notation. NIOSH has no REL but concurs (Ex. 8-47, Table N6A) with the limit OSHA is proposing for construction, maritime, and agriculture, which is a 10-ppm 8-hour TWA. This is the limit recently established for this substance in general industry.

1,2,3-Trichloropropane is a colorless to straw-colored, combustible liquid with an odor similar to that of chloroform. This substance finds use as a degreasing agent, a paint and varnish remover, and a solvent. It is also used in chemical synthesis (HSDB 1988).

In addition to liver toxicity, 1,2,3trichloropropane causes irritation of the eyes, skin, and mucous membranes and narcosis in experimental animals. The

oral LDso in rats is 320 mg/kg; in mice, the LCso is 3400 mg/m3 for 2 hours (RTECS 1990). The dermal LDso in rabbits is 1770 mg/kg (RTECS 1990). Acutely poisoned animals surviving for 1 week to 10 days after exposure died of liver damage (Proctor, Hughes, and Fischman 1988, p. 491). Instilled into the eves of rabbits, 1,2,3-trichloropropane caused severe irritation (RTECS 1990; Proctor, Hughes, and Fischman 1988, p. 491). Applied to the skin of rabbits, the liquid caused defatting and irritation described by the investigators as "intense" (McOmie and Barnes 1949). Five of six rats exposed to a 1000-ppm concentration of 1,2,3-trichloropropane died after four-hour exposures. Rats and guinea pigs exposed at 800, 2100, or 5000 ppm for 30 minutes showed central nervous system depression, which progressed, at the higher exposure levels, to narcosis and convulsions (Lewis 1979). Daily 10-minute exposures at 2500 ppm for 10 days killed 7 of 10 mice (McOmie and Barnes 1949). Animals exposed once for four hours to 1,2,3-trichloropropane at concentrations of 125, 340, 700, or 2150 ppm showed dose-related signs of irritation, which included, at 700 or 2150 ppm, labored respiration, inactivity, and eye and nose irritation; at autopsy, however, no organ or other damage was apparent (McOmie and Barnes 1949).

Drew, Patel, and Lin (1978/Ex. 1–313) noted changes in rat liver enzymes after a single four-hour exposure to 500 ppm, and Russian studies indicate that morphologic changes and metabolic lesions of the liver, kidney, and lungs occurred in mice exposed continuously to 1,2,3-trichloropropane concentrations of 0.007 to 0.3 ppm (Sidorenko, Tsulaya, Bonashevskaya, and Shaipak 1979/Ex. 1–669; Sidorenko, Tsulaya, Koreneveskaya, and Bonashevskaya 1976/Ex. 1–668; Tsulaya, Bonashevskaya, Zykova et al. 1977/Ex.

A National Toxicology Program (NTP) prechronic study, in which rats were gavaged daily with 1,2,3-trichloropropane at 8, 16, 32, 63, 125, or 250 mg/kg body weight for 120 days, showed good survival in all but the highest dose group (NTP 1983a). Statistically significant changes in the liver and kidneys, as well as necrosis and irritation of the nasal passages, occurred in the 63- and 125-mg/kg dose

groups. Decreases in red blood cell counts and hematocrits were also seen, even in the 16-mg/kg dose group. 1,2,3-Trichloropropane did not affect testicular weight, sperm count, or morphology. The NTP found this substance to be genetically active in three bioassays. Hardin, Bond, Sikov et al. (1981/Ex. 1–699) did not find 1,2,3-trichloropropane to be fetotoxic or teratogenic.

Human volunteers found exposure to 1,2,3-trichloropropane objectionable because of eye and upper respiratory tract irritation, and many found 50 ppm an unacceptable level for a full-shift exposure (Silverman, Schulte, and First 1946/Ex. 1–142). At a 100-ppm concentration, all of the volunteers noted eye and nose irritation and reported that the odor was unpleasant (Silverman, Schulte, and First 1946/Ex. 1–142).

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 10 ppm for 1,2,3-trichloropropane. The Agency preliminarily concludes that a 10-ppm 8hour TWA limit is necessary to protect workers in construction, maritime, and agriculture against the significant risks of liver and kidney damage and eve and throat irritation that are potentially associated with exposures to this substance at levels above the proposed PEL. OSHA is aware that a lower PEL may be appropriate for trichloropropane. However, as discussed above, the primary purpose of the current rulemaking is to extend the protection afforded to workers in some sectors to those in all sectors. In a future PEL update rulemaking, OSHA will carefully consider the need for a lower PEL for this substance.

Introduction

Kidney damage is the basis for proposing to establish or revise the PELs for six of the substances in this group. These chemicals, their CAS and HS numbers, and their current PELs in construction and maritime are shown in Table C4–2. Their 1987–1988 ACGIH TLV*s and NIOSH RELs are also shown. The PELs OSHA is proposing for these kidney toxins in construction, maritime, and agriculture appear in the last column of Table C4–2. Promulgation of the proposed PELs will make their limits consistent across general industry.

TABLE C4-2.—LIST OF SUBSTANCES FOR WHICH PROPOSED LIMITS ARE BASED PRIMARILY ON AVOIDANCE OF KIDNEY TOXICITY

H.S. No./chemical name	CAS No.	Current OSHA PEL in construction and maritime *	1987-1988 ACGIH TLV***	NIOSH REL*	Proposed OSHA PEL in construction, maritime, and agriculture *
129 1,3-Dichloropropene	77-73-6 78-10-4 87-68-3 108-10-1	100 ppm TWA	1 ppm TWA, Skin	50 ppm TWA	5 ppm TWA. 10 ppm TWA. 0.02 ppm TWA. 50 ppm TWA, 75 ppm STEL.

*OSHA's TWA limits are for 8-hour exposures; its STELs are for 15 minutes only unless otherwise specified; and its ceilings are peaks not to be exceeded for any period of time; OSHA's PELs do not currently apply in Agriculture.

The ACGIH TLV-TWA is for an 8-hour exposure; its STELs are 15-minute limits not to be exceeded more than 4 times per day with a minimum of 60 minutes between successive STEL exposures; and its ceilings are peaks not to be exceeded for any period of time. An A2 designation means that the ACGIH classifies the substance as a suspected human carcinogen.

*NIOSH TWA limits are for 10 hour/day, 40 hour/week exposures unless otherwise specified, and its ceilings are peaks not to be exceeded for any period of time unless a duration is specified in parentheses.

Description of the Health Effects

The precise mechanism by which these chemicals damage the kidneys is unknown. Typically, these substances are selectively toxic to cells in the renal tubules, perhaps because impaired transport causes the chemical to collect in these cells. In addition to its function in the excretion of wastes, the kidney plays an important role in the regulation of total body homeostasis. This organ regulates extracellular volume, controls electrolyte and acid-base balance, and forms several hormones that control systemic metabolism. Depending on their particular site of action, nephrotoxicants can interfere with hydration, the proper excretion of the body's wastes, electrolytic balance, metabolism, or the maintenance of correct acid-base balances. Like the hepatotoxic effects previously described, the least severe lesions caused by nephrotoxic compounds are graded and reversible. The earliest changes are usually alterations in the activities of specific enzymes in the tubular cells. These changes may be accompanied by minor morphological alterations of the cells that are visible only with an electron microscope. Higher doses or more sustained exposures are required to cause cellular necrosis that is visible with light microscopy. Because of the reserve capacity of the kidneys, a significant degree of tubular cell necrosis must occur before it is reflected by measurable alterations in kidney function. Thus, indicators of impaired renal function that can be measured in humans, such as proteinuria, glucosuria, and increased BUN, are relatively insensitive indicators of early kidney damage. Other indicators of significant kidney damage include increased kidney weight, swelling of the tubular epithelium, fatty degeneration of tubular epithelium, and the presence of tubular casts in the urine.

Dose-Response Characteristics

Kidney damage, like liver damage, is progressive; only at the earlier stages are nephrotoxic effects reversible. With continued exposure, the damage becomes more extensive, until it reaches the point at which it cannot be repaired. The toxicity of the kidney-damaging chemicals included in this group also increases as dose increases. For most nephrotoxins, there appears to be a noobserved-effect level. Workplace exposures to concentrations of these substances at levels at or below the proposed limits are unlikely to cause observable kidney effects in most workers. OSHA has preliminarily determined that the nephrotoxic risks being protected against are significant at the current PELs or in the absence of a PEL and believes that kidney damage constitutes a material health impairment within the meaning of the Act. The PELs being proposed are those already established in general industry or other sectors, and promulgation will thus make the PELs for these substances consistent across all regulated sectors.

1,3-DICHLOROPROPENE

CAS: 542-75-6; Chemical Formula: CHCl=CH-CH₂Cl

H.S. No. 1129

In construction, maritime, and agriculture, OSHA has no PEL for 1,3dichloropropene. NIOSH has no REL but concurs (Ex. 8-47, Table N6A) with the proposed limit. The 1987-1988 ACGIH TLV* for this substance is 1 ppm as an 8-hour TWA, with a skin notation. The Agency is proposing an 8-hour TWA limit of 1 ppm, with a skin notation, for this dichloropropene in construction, maritime, and agriculture. Promulgation of this PEL will make the limit for this

substance consistent across all regulated sectors.

This compound occurs in two forms: as the cis- and the trans-isomer. It is a colorless to straw-colored liquid that is used in organic synthesis, as a soil fumigant, and as a pesticide on a variety of crops (HSDB 1989). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

In male and female rats, the acute oral LD₅₀s for a 92-percent mixture of the cisand trans-isomers of 1,3dichloropropene were 713 and 470 mg/ kg, respectively; post-mortem examination showed liver and kidney damage and evidence of possible lung injury (Torkelson and Oyen 1977/Ex. 1-532). The dermal LD50 in rabbits for a 92percent undiluted mixture was 504 mg/ kg, but a 10-percent solution administered by gavage at a dose of 125 or 250 mg/kg was lethal to some of the animals (Torkelson and Oyen 1977/Ex. 1-532). Contact with the liquid was irritating to the eyes and skin of rabbits (Torkelson and Oyen 1977/Ex. 1-532).

Inhalation exposures to 1,3dichloropropene vapor concentrations above 2700 ppm produced eye and nasal irritation and severe lung, nasal, kidney, and liver damage in rats (Torkelson and Oyen 1977/Ex. 1-532). Exposure to 1000 ppm caused eye and nasal irritation, lacrimation, and, if prolonged, unconsciousness; rats exposed to 1000 ppm for two hours died, but those exposed for one hour survived (Torkelson and Oyen 1977/Ex. 1-532). Guinea pigs exposed to 400 ppm for a single 7-hour period died, while rats exposed similarly survived but had obvious lung congestion (Torkelson and Oyen 1977/Ex. 1-532). Rats, rabbits, guinea pigs, and dogs were exposed 7

hours/day, 5 days/week for 6 months to 1-ppm or 3-ppm concentrations of 1,3-dichloropropene (Torkelson and Oyen 1977/Ex. 1-532). No adverse effects were observed in any of the animals exposed at 1 ppm. Of the animals exposed at 3 ppm, only male rats showed adverse effects; these animals had reversible cloudy swelling of the renal tubular epithelium (Torkelson and Oyen 1977/Ex. 1-532).

In humans, acute exposures to 1,3dichloropropene cause skin, eye, and respiratory irritation (Torkelson and Oyen 1977/Ex. 1–532). There are no data on the effects in humans of chronic exposure to this substance.

OSHA is proposing an 8-hour TWA limit of 1 ppm, with a skin notation, for 1,3-dichloropropene in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in construction, agriculture, and maritime against the significant risks of eye and mucous membrane irritation and lung, kidney, and liver damage that are associated with exposure to this substance. A skin notation is proposed to protect against 1,3-dichloropropene's ability to cause systemic toxicity when absorbed through the skin. Promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

DICYCLOPENTADIENE CAS: 77-73-6; Chemical Formula: C₁₀H₁₂ H.S. No. 1132

OSHA has no limit for dicyclopentadiene (DCPD) in construction, maritime, or agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the proposed limit. The 1987–1988 ACGIH TLV* for dicyclopentadiene is 5-ppm as an 8-hour TWA. In construction, maritime, and agriculture, OSHA is proposing an 8-hour TWA PEL of 5 ppm. This is the limit recently established for this substance in general industry.

At room temperature, DCPD is a solid that has a disagreeable odor. This substance is used in the production of chlorinated hydrocarbon pesticides, to stabilize organophosphorus pesticides, and to produce elastomers, paints, varnishes, and flame retardants (Clayton and Clayton 1981, p. 3242; ACGIH 1986, p. 194). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

The health effects associated with exposure to DCPD include severe eye and moderate skin irritation (RTECS 1990), as well as renal damage and

possible pulmonary damage. By the oral and intraperitoneal routes, DCPD is extremely toxic, with an oral LD50 value of 353 mg/kg and an intraperitoneal LD50 value of 200 mg/kg in rats (RTECS 1990); fatalities occurred among rats within 60 minutes of exposure to the saturated vapor (Kinkead, Pozzani, Geary, and Carpenter 1971/Ex. 1-606). The LC50 in rats is 359 ppm for 4 hours, and the dermal LD50 in rabbits is 5080 mg/kg (RTECS 1990). Kinkead and associates (1971/Ex. 1-606) report that rats exposed repeatedly for 10 days survived concentrations of 72 or 146 ppm but had convulsions and succumbed at the 332ppm level; autopsy revealed lung hemorrhage and blood in the intestines; in the females, hemorrhage of the thymus also occurred (Kinkead, Pozzani, Geary, and Carpenter 1971/Ex. 1-606). Chronic exposures of 7 hours/day for 89 days produced kidney damage and some pulmonary effects in rats exposed to concentrations of 35 or 74 ppm; the noeffect level for these endpoints in rats was determined to be below 19.7 ppm. Dogs exposed to dicyclopentadiene concentrations of 9, 23, or 32 ppm on the same regimen exhibited only minimal effects (Kinkead, Pozzani, Geary, and Carpenter 1971/Ex. 1-606).

Human sensory response tests resulted in findings of mild eye and throat irritation within 7 minutes' exposure to DCPD vapor at a concentration of 1 ppm and of olfactory fatigue within 24 minutes; a 30-minute exposure to a 5.5-ppm concentration produced no olfactory fatigue (ACGIH 1986/Ex. 1-3, p. 194). Subjective complaints of headache during the first two months of occupational exposure disappeared during the following 3 months of exposure, suggesting that humans develop a tolerance for this substance (ACGIH 1986/Ex. 1-3, p. 194).

Based on this evidence in animals and humans, OSHA is proposing an 8-hour TWA PEL of 5 ppm for dicyclopentadiene. The Agency preliminarily concludes that this limit will protect workers in construction, maritime, and agriculture against the significant risks of kidney injury, pulmonary effects, and irritation that are associated with occupational exposure to DCPD at the levels permitted in the absence of an OSHA limit in these sectors. OSHA believes that the proposed PEL is necessary to substantially reduce this risk. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. ETHYL SILICATE

CAS: 78–10–4; Chemical Formula: Si[OC₂H₅)₄ H.S. No. 1168

OSHA's permissible exposure limit for ethyl silicate in construction and maritime is 100 ppm as an 8-hour TWA. There is no PEL in agriculture. NIOSH has no REL for ethyl silicate but concurs (Ex. 8–47, Table N1) with the selection of the proposed limit. The 1987–1988 ACGIH TLV* for this substance was an 8-hour TWA of 10 ppm. OSHA is proposing a 10 ppm 8-hour TWA PEL for ethyl silicate in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry.

Ethyl silicate is a colorless liquid with a faint odor. It is used as an adherent in controlled-release pesticides, as a weatherproofing agent on mortar and cement and in paints and other coatings. It is also used as a chemical intermediate (ACGIH 1986, p. 264; HSDB 1986). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

In addition to kidney damage, ethyl silicate causes both irritation and systemic toxicity. The oral LD50 in rats is 6270 mg/kg, and the lowest lethal concentration in rats is 1000 ppm for 4 hours (RTECS 1990). The dermal LDso in rabbits is 5878 mg/kg (RTECS 1990). In guinea pigs and rats, a 60-minute exposure of 2000 ppm was reported as the maximal duration/concentration that did not cause serious disturbances: 500 ppm was the maximal no-effect exposure level for an exposure of several hours' duration (Smyth and Seaton 1940b/Ex. 1-376). Thirty-day exposures to 400 ppm ethyl silicate for 7 hours/day caused significant mortality in rats and damage to the lungs, liver, and kidney in the surviving animals. Exposures of rats, guinea pigs, and mice to 88, 50, or 23 ppm for 90 days (7 hours/ day, 5 days/week) resulted only in decreased kidney weights in mice exposed at the 88-ppm level (Pozzani and Carpenter 1951/Ex. 1-166). In another study, Kasper, McCord, and Fredrick (1937/Ex. 1-1155) showed that animals exposed to 164 ppm ethyl silicate for 17 8-hour days showed less weight gain than did controls. Rowe and associates (1948/Ex. 1-359) reported that three 7-hour exposures to a 1000-ppm concentration were fatal to 4 of 10 rats; similar exposures to 500 ppm caused pronounced kidney changes and slight lung irritation. Four to 10 similar exposures at 250 ppm caused slow weight loss and some lung and renal changes; at 125 ppm, slight to moderate kidney damage was observed (Rowe, Spencer, and Bass 1948/Ex. 1-359).

Smyth and Seaton (1940b/Ex. 1-376) reported that exposure to a concentration of 1200 ppm causes lacrimation in humans and that 250 ppm causes eye and nose irritation. Very brief exposures to high concentrations of ethyl silicate cause severe irritation in humans. At a 3000-ppm concentration, the irritation caused even by brief exposures is reported to be intolerable. At a 1200-ppm concentration, exposure causes a stinging sensation and tearing; at 700 ppm, mild stinging of the eyes occurred. Even at a concentration of 250 ppm, slight irritation of the eyes was reported (Proctor, Hughes, and Fischman 1988, p. 256).

In construction, maritime, and agriculture, OSHA is proposing a PEL for ethyl silicate of 10 ppm as an 8-hour TWA. The Agency preliminarily concludes that this limit is necessary to protect workers in construction, maritime, and agriculture from the significant risk of renal damage that is associated with exposures to this substance at concentrations above the proposed PEL. OSHA considers these effects material impairments of health and believes that the proposed PEL will reduce this significant risk. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. HEXACHLOROBUTADIENE CAS: 87–68–3; Chemical Formula: CCl₂=CCl—CCl=CCl₂

H.S. No. 1195

In construction, maritime, and agriculture, OSHA has no exposure limit for hexachlorobutadiene (HCBD). NIOSH has no REL for hexachlorobutadiene but concurs (Ex. 8-47. Table N6A) with the limit being proposed. The ACGIH has a TLV®-TWA of 0.02 ppm, and a skin notation, for this substance, which it also classifies as a suspected human carcinogen (A2). OSHA is proposing an 8-hour TWA PEL of 0,02 ppm for HCBD in construction, maritime, and agriculture. Promulgation of this limit will make the PEL for this substance consistent across all regulated sectors.

Hexachlorobutadiene is a heavy, clear liquid. This substance is used as a chemical intermediate in the production of lubricants and of rubber compounds. It also finds use in the recovery of chlorine-containing gas in chlorine plants and as a gyroscope fluid (IARC 1979, p. 180).

In addition to kidney injury, exposure to hexachlorobutadiene causes respiratory and other irritation, as well as cancer. The LD sos reported for mice. rats, and guinea pigs are 110, 90, and 90 mg/kg, respectively (RTECS 1990), and

the dermal LDso in rabbits is 1211 mg/kg (RTECS 1990). Rats survived exposures to a 161-ppm concentration for 0.88 hour or to 34 ppm for 3.3 hours; most guinea pigs and cats similarly exposed died (Kociba, Schwetz, Keyes et al. 1977/Ex. 1-494). Another inhalation study in rats showed eye and nose irritation, respiratory difficulty, and damage to kidney tissue and the adrenal cortex after two 4-hour exposures at 250 ppm; twelve 6-hour exposures to 100 ppm caused eye and nose irritation, respiratory difficulty, weight loss, anemia in the female animals, and kidney and adrenal damage; fifteen 6hour exposures to 25 ppm caused retarded weight gain in females. respiratory difficulty, and kidney damage; fifteen 6-hour exposures to a 10-ppm concentration caused retarded weight gain in females but no systemic injury; and fifteen 6-hour exposures at 5 ppm resulted in no adverse effects

(Gage 1970/Ex. 1-318).

Reproductive studies in male and female rats demonstrated multiple toxicological effects, including kidney damage in both sexes and increased liver weight in males, at the high-dose level of 20 mg/kg/day. Dietary administration of 20, 2, or 0.2 mg/kg daily had no effect on conception percentages, gestational survival. neonatal survival, neonatal sex ratios, neonatal morphology, or neonatal body weights (except for the high-dose neonates) (Schwetz, Smith, Humiston et al. 1977/Ex. 1-368). Results of lifetime dietary studies suggest that the no-effect level for hexachlorobutadiene in rats is 0.2 mg/kg/day, that a clear doseresponse relationship exists for HCBDinduced toxicity affecting primarily the kidney, and that carcinogenic effects (i.e., renal neoplasms) result from ingestion of 20 mg/kg/day (Kociba, Schwetz, Keyes et al. 1977/Ex. 1-494) These authors also reported that HCBDinduced neoplasms occurred in these animals only at HCBD doses higher than those causing discernible renal injury. The International Agency for Research on Cancer (IARC) has concluded that there is limited evidence that hexachlorobutadiene is carcinogenic in animals (IARC 1979, p. 189). NIOSH also (Ex. 8-47, Table N6A) considers hexachlorobutadiene a potential human carcinogen.

Based on this evidence, OSHA is proposing an 8-hour TWA limit of 0.02 ppm for hexachlorobutadiene in construction, maritime, and agriculture. Assuming a 10-m3 per day breathing volume per 8-hour workshift and a 70-kg body weight for humans, the proposed limit would correspond to a daily hexachlorobutadiene intake of

approximately 0.03 mg/kg, which is about 10 times below the observed noeffect level in rats fed hexachlorobutadiene. The Agency preliminarily concludes that this 0.02ppm limit will protect workers in construction, maritime, and agriculture from the significant risks of kidney damage; eye, skin, and pulmonary irritation; and renal neoplasms that are potentially associated with exposure to HCBD at levels above the proposed limit. OSHA considers these effects material impairments of health and believes that the proposed PEL is necessary to substantially reduce this risk. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

HEXONE (METHYL ISOBUTYL KETONE)

CAS: 108-10-1; Chemical Formula: CH3COCH2CH(CH3)2 H.S. No. 1203

In construction and maritime, OSHA's 8-hour TWA limit for hexone (methyl isobutyl ketone, or MIBK) is 100 ppm. The ACGIH has established a TLV*-TWA of 50 ppm and a TLV®-STEL of 75 ppm for this substance. NIOSH has a TWA REL of 50 ppm for MIBK but concurs (Ex. 8-47, Table N1) that the limits OSHA is proposing are appropriate. OSHA is proposing a 50ppm 8-hour TWA limit and a 75-ppm STEL for hexone in construction. maritime, and agriculture. These are the limits recently established for this substance in general industry.

Hexone is a clear liquid with a characteristic ketone odor. This substance is used as a nitrocellulose and cellulose ether solvent and a solvent for paints, varnishes, protective coatings, fats, waxes, oils, gums, and resins (ACCIH 1986, p. 402; HSDB 1986). It also finds use in drycleaning preparations and in the synthesis of methyl isobutyl carbinol (HSDB 1986).

In addition to renal toxicity, hexone causes irritation of the eyes, mucous membranes, and skin and, at high concentrations, is a narcotic in animals (Proctor, Hughes, and Fischman 1988, p. 337). The oral LD50 in rats is 2080 mg/kg, and the LC50 in the same species is 8000 ppm for 4 hours (RTECS 1990). A 4-hour exposure to 4000 ppm MIBK killed all exposed rats, but a similar exposure to 2000 ppm was not fatal to these animals (Smyth, Carpenter, and Weil 1951/Ex. 1-439). Guinea pigs exposed to a MIBK concentration of 10,000 ppm immediately showed signs of irritation (Specht, Miller, Valaer, and Sayers 1940/Ex. 1-1179).

MacEwen, Vernot, and Haun (1971/ Ex. 1-194) exposed rats, mice, dogs, and monkeys to 100 or 200 ppm MIBK for two weeks and noted no signs of intoxication; however, rats exposed to 100 ppm had heavier kidneys and higher kidney-to-body-weight ratios at autopsy, and, at 200 ppm, the livers of exposed animals were heavier as well. Postmortem examination revealed nephrosis of the proximal tubules. The same authors (MacEwen, Vernot, and Haun 1971/Ex. 1-194), exposed rhesus monkeys, dogs, and rats continuously for 90 days to MIBK concentrations of 100 ppm. These authors observed no significant changes in clinical chemistry or blood test results, although the rats had heavier kidneys and livers, reversible hyaline droplet degeneration of the proximal tubules of the kidneys, and some necrosis of the tubules at

Silverman, Schulte, and First (1946/ Ex. 1-142) determined that the maximum dose of MIBK tolerable to human volunteers for eight hours was 100 ppm; at 200 ppm, these subjects found the odor of MIBK objectionable and the vapor irritating. Linari and co-workers (1964/Ex. 1-1159) reported that more than half of all workers exposed to 500 ppm of MIBK for 20 to 30 minutes daily. and perhaps to 80 ppm for the remainder of the shift, experienced weakness, loss of appetite, headache, burning eyes, nausea, vomiting, and sore throat; several of these workers also reported insomnia, somnolence, heartburn, and intestinal pain. Some workers had enlarged livers and others had colitis. Clinical test results on these workers were normal (Linari, Perrelli, and Varese 1964/Ex. 1-1159).

In a follow-up study on this same group of centrifuge operation workers, Armeli and co-workers (1968/Ex. 1–1028) determined that reduction of MIBK levels (during the 15 to 30 minutes of centrifuge operation) to 100 to 105 ppm, and (for the remainder of the shift) to 50 ppm had also significantly reduced the symptomatology reported earlier by these workers. However, liver enlargement persisted in two workers, and a few workers continued to report gastrointestinal and nervous system effects (Armeli, Linari, and Martorano 1968/Ex. 1–1028).

Elkins (1959f/Ex. 1-734) noted that exposure to 100 ppm during boot-waterproofing operations caused workers to develop headache and nausea; another similarly exposed group experienced only irritation at 100 ppm. Human volunteers developed headaches, eye irritation, sore throat, and nausea and experienced weakness

when they were exposed for an unspecified time to a hexone concentration of 80 to 500 ppm (Proctor, Hughes, and Fischman 1988, p. 337). Hexone causes defatting of the skin on repeated or prolonged contact (AIHA

OSHA is proposing an 8-hour TWA limit of 50 ppm and a 15-minute STEL of 75 ppm for hexone in construction, maritime, and agriculture. The Agency preliminarily concludes that these limits will protect workers in construction, maritime, and agriculture from the significant risks of headache, nausea, and irritation, as well as the potential kidney and liver effects that are associated with exposures to hexone. OSHA considers these effects material impairments of health and believes that the proposed PELs are necessary to substantially reduce these risks. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

URANIUM (SOLUBLE COMPOUNDS) CAS: Varies; Chemical Formula: Varies

In construction and maritime, OSHA's PEL for the soluble compounds of uranium is an 8-hour TWA of 0.2 mg/m³, measured as uranium. There is no PEL in agriculture. The ACGIH TLV*s for the soluble uranium compounds are 0.2 mg/m³ as an 8-hour TWA and 0.6 mg/m³ as a 15-minute STEL. NIOSH has no REL but concurred (Ex. 8-47, Table N1) with the proposed limit when it was established recently in general industry. In construction, maritime, and agriculture, OSHA is proposing an 8-hour TWA of 0.05 mg/m³.

The soluble compounds of uranium most common in industrial use are uranium hexafluoride, uranyl acetate, uranyl chloride, uranyl fluoride, uranyl nitrate, and uranyl sulfate. The physical and chemical properties and uses of these compounds vary with the particular substance.

Exposure of animals to the soluble compounds of uranium may cause both chemical poisoning and radiation injury (Clayton and Clayton 1981, p. 1996). The soluble uranium compounds are chemically more toxic than the insoluble compounds, but both the soluble and insoluble compounds have the same potential to cause radiation injury (Clayton and Clayton 1981, p. 2000; Klaassen, Amdur, and Doull 1986, p. 695). The most significant damage occurs to the kidneys and lungs, but the eyes and central nervous system also may be adversely affected. Data suggest that exposure to uranium also causes carcinogenic and mutagenic effects. The intraperitoneal LD50 for uranyl nitrate is

400 mg/kg in mice (Sax and Lewis 1989, p. 3446). Exposure to the dusts and mists of the soluble uranium compounds is fatal to almost all animals exposed by inhalation to 20 mg/m3 daily for 1 month; death is caused by acute renal failure and pulmonary insufficiency. Exposure levels of 0.2 mg/m3 are occasionally fatal, while levels of 0.05 mg/m³ produce no detectable effects (Clayton and Clayton 1981, p. 2001; Proctor, Hughes, and Fischman 1988, p. 501). Rats, monkeys, and dogs exposed to an airborne concentration of 5 mg/m3 soluble uranium compounds for 6 hours/ day, 5 days/week for 5 years showed no evidence of acute uranium toxicity, although autopsy 6.5 years after cessation of exposure revealed an increase in the incidence of pulmonary neoplasms in the dogs and monkeys (AIHA 1978). Dogs fed 0.2 mg/kg uranyl nitrate for 1 year tolerated the exposure but exhibited growth deficits and abnormal urinary protein and glucose levels indicative of renal damage (Clayton and Clayton 1981, p. 2001). Male rats fed 0.1 percent uranyl nitrate and female rats fed 0.5 percent uranyl nitrate for 2 years showed no adverse growth effects; exposure to 0.05 percent for 2 years caused no effects (Clayton and Clayton 1981, p. 2001). Rabbits exposed to soluble uranium salts developed neurological symptoms and pathological changes in the cerebral and cerebellar cortices; exposed dogs developed epithelial degeneration of the choroid plexi (HSDB 1986). All soluble uranium compounds are lethal when applied in a single dose to rabbits' skin; some are also lethal when placed in the conjunctival sac (Clayton and Clayton 1981, p. 2000). Most soluble uranium compounds also damage the eye itself on contact (Grant 1986, p. 965). Exposure to 0.18 mg/ml uranyl nitrate produced chromatid and chromosomal damage in Chinese hamster cells in vitro (HSDB

As in animals, exposure of humans to the soluble compounds of uranium may cause both chemical poisoning and radiation injury. Acute exposure to the dusts of the soluble compounds irritates the mucous membranes, eyes, and respiratory tract, and acute overexposure via any route of administration causes kidney damage (Proctor, Hughes, and Fischman 1988, p. 502). Several acute exposures have been documented. Two deaths occurred after exposure to gaseous uranium hexafluoride: One worker died 10 minutes after a 5-minute exposure, and the other died 70 minutes after a brief exposure. Both cases were complicated by exposure to steam, which caused

third-degree burns and liberated hydrofluoric acid (Clayton and Clayton 1981, pp. 2008-2009). In another incident, exposure to gaseous uranium hexafluoride (and its hydrolysis products, including hydrofluoric acid) caused chemical conjunctivitis with corneal necrosis, cough, and shortness of breath, accompanied by increased density of bronchovascular markings and hilar shadows on chest X-ray, laryngeal hemorrhages, and albuminuria, microhematuria, an elevated blood urea nitrogen level, and increased urinary solids (which are indicative of kidney injury and renal insufficiency). With treatment, recovery was complete (Clayton and Clayton 1981, p. 2009). Uranium miners in the United States, Czechoslovakia, and Canada have an excess incidence of deaths from respiratory cancer and pulmonary insufficiency, which are presumed to be caused by radiation injury from radon gas, a byproduct of uranium decay (Rom 1983, p. 688). A study of the risk of respiratory deaths among uranium miners in the U.S. showed the following dose-response: miners exposed for 5 to 9.9 years had a 2-fold increase in risk; miners exposed for 10 to 24.9 years had a 3.6-fold increase in risk; and those exposed for greater than 24.9 years had a 3.75-fold increase in risk. Smoking was shown both to increase the risk of death from respiratory disease and to shorten the neoplastic latency period (Clayton and Clayton 1981, pp. 2010-2011). In contact with the skin, uranyl nitrate causes burns (Klaassen, Amdur, and Doull 1986, p. 628). Uranium miners have elevations

of all types of chromosome aberrations; an increase in chromosomal aberrations in cultured lymphocytes is correlated with exposure to radon daughters (Rom 1983, p. 689). Uranyl nitrate is mutagenic to lymphocytes at 100 µg/l (RTECS 1989).

Based on this evidence in humans and animals, OSHA preliminarily concludes that exposure to the soluble compounds of uranium is associated with kidney and liver damage and, perhaps, of cancer. The Agency believes that the proposed PEL of 0.05 mg/m3 is necessary to protect workers in construction, maritime, and agriculture from the significant risk of incurring these exposure-related effects, which OSHA considers material impairments of health within the meaning of the Act. In addition, promulgation of this limit will make OSHA's PEL for these substances consistent across all regulated sectors.

Preliminary Conclusion for Both Liver and Kidney Toxins

The health effects associated with occupational exposures to the hepatoand nephrotoxins shown in Tables C4-1 and C4-2 can be acute or chronic, reversible or irreversible, temporarily disabling or threatening to life. Workers in construction, maritime, and agriculture who experience chemically induced hepatotoxic or nephrotoxic effects may have enlarged livers, high blood pressure, hormonal imbalances, and/or organ necrosis. In addition, exposure to these substances is associated with a host of other adverse health effects, ranging from pulmonary irritation to cancer, and OSHA preliminarily concludes that the

proposed limits are necessary to substantially reduce the risk of these effects as well. In addition, promulgation of these limits will make OSHA's PELs for these substances consistent across all regulated sectors.

5. Substances for Which Proposed Limits are Based on Avoidance of Ocular Effects

Introduction. Seven of the chemicals for which OSHA is proposing limits have the potential to cause serious ocular effects among workers in a variety of occupational settings. Some of the chemicals in this group are also sensory irritants and have other target organ effects; these substances have been placed in this section of the proposal because their limits are based primarily on their ability to cause permanent damage to the cornea, lens, or optic nerve of the eyes of exposed workers.

Table C5-1 lists these ocular toxins, along with their CAS numbers, an OSHA-assigned HS number that is used to facilitate indexing of the rulemaking docket, their 1987-1988 ACGIH TLV®s, and their NIOSH RELs (if any). In addition, Table C5-1 shows OSHA's current PELs for these substances in construction and maritime. (OSHA currently has no PELs in agriculture.) The right-hand column in Table C5-1 shows the PEL recently promulgated for each substance in the Agency's final Air Contaminants standard for general industry; these are the limits being proposed for these substances today in construction, maritime, and agricultural workplaces.

TABLE C5-1.—SUBSTANCES FOR WHICH PROPOSED LIMITS ARE BASED ON AVOIDANCE OF OCULAR EFFECTS

H.S. No./chemical name	CAS No	Current OSHA PEL in construction and maritime	1987-1988 ACGIH TLV 9***	NIOSH REL /+/	Proposed OSHA PEL in construction, maritime, and agriculture
1172 N-Ethylmorpholine	100-74-3	20 ppm TWA, Skin.	5 ppm TWA, Skin		5 ppm TWA, Skin.
1209 Hydrogen sulfide	7783-06-4	200000	10 ppm TWA, 15 ppm STEL	10 ppm Ceiling (10 min).	10 ppm TWA, 15 ppm STEL.
2094 Hydroquinone	123-31-9	2 mg/m ³ TWA	2 mg/m³ TWA	2 mg/m ³ Ceiling (15 min).	2 mg/m³ TWA.
1252 Methyl alcohol	67-56-1	200 ppm TWA	200 ppm TWA, 250 ppm STEL, Skin.	200 ppm TWA, 800 ppm Ceiling (15 min).	200 ppm TWA, 250 ppm STEL, Skin.
1282 Naphthalene2138 Quinone (p-Benzoquinone)	681-84-5 91-20-3 106-51-4	10 ppm TWA	1 ppm TWA		1 ppm TWA. 10 ppm TWA, 15 ppm STEL. 0.1 ppm TWA.

^{*}OSHA's TWA limits are for 8-hour exposures, its STELs are for 15 minutes unless otherwise specified, and its ceilings are peaks not to be exceeded for any

period of time.

***OSHA's PELs do not currently apply in Agriculture [or in longshoring except in circumstances where the General Duty clause (Sec. 5(a)(1) of the Act) is

cited).

***The ACGIHTLY®_TWA is for an 8-hour exposure; its STELs are 15-minute limits not to be exceeded more than 4 times per day with a minimum of 60 minutes between successive STEL exposures; and its ceilings are peaks not to be exceeded for any period of time.

†NIOSH TWA limits are for 10 hour/day, 40 hour/week exposures unless otherwise specified, and its ceilings are peaks not to be exceeded for any period of time unless a duration is specified in parentheses.

For N-ethylmorpholine, OSHA's current PEL in construction, shipyards, and marine terminals is 20 ppm, with a skin notation; the Agency is proposing to reduce the 8-hour TWA PEL to 5 ppm and to retain the skin designation for this substance. For three of these substances-hydrogen sulfide, methyl alcohol, and naphthalene-OSHA is proposing to add short-term exposure limits to existing 8-hour TWA PELs, and for another substance, methyl silicate. OSHA is proposing to revise the current 5 ppm ceiling limit to a 1 ppm 8-hour TWA PEL. For hydroquinone, OSHA is retaining the PEL that currently exists in construction and maritime and proposing to extend it to agriculture, and for guinone, the Agency is proposing to reduce the limit to 0.1 ppm.

Description of the health effects.

Damage to the eye caused by exposure to the chemicals in this group can occur in the form of corneal, lens, retinal, ganglion cell layer, or optic nerve effects. Depending on the severity of the exposure, individual susceptibility, and the particular chemical and circumstances involved, this damage may be transient, temporarily disabling, or permanently blinding.

Corneal effects. The cornea and conjunctiva are the outer surfaces of the eye and are thus directly exposed to external insults. Since the cornea must maintain transparency to remain functional, scar formation after injury to the cornea can destroy visual function completely. Recent evidence suggests that the transparency of the cornea is maintained by thin inner and outer boundary layers and that the death of these layers leads to loss of transparency (Potts 1986/Ex. 1-174). The corneal epithelium (outer layer) sometimes regenerates, depending on the depth of the burn or insult and the nature of the toxicant.

The vapors of some chemicals, including methyl silicate, produce painful corneal epithelial injuries that are associated with a delay in the onset of symptoms. These substances can continue to cause pain and loss of corneal epithelial cells for several hours after exposure. Typically, there is no discomfort during the actual exposure to the vapor, but several hours later, the eyes begin to burn, vision blurs, and conjunctival hyperemia, tearing, photophobia, and squinting occur (Grant 1986/Ex. 1-975). Possible mechanisms of action are enzyme inhibition, denaturing of other proteins, alteration of the DNA. and interference with the mitotic process; after a period of exposure, the affected cells die. Although the damaged epithelium sometimes regenerates after

this type of injury, the damage can also involve the corneal stroma and endothelium, leading to scarring, vascularization, opacity, and loss of vision. The poor warning properties characteristic of these substances (i.e., their failure to cause immediate irritation and pain) make the establishment of protective exposure limits particularly important.

Exposure to the vapors of some of the substances in this group produces painless edema of the corneal epithelium, which can be accompanied by the delayed onset of visual haloes. A chemical that produces these effects is N-ethylmorpholine, a catalyst used to manufacture urethane foam. Painless edema generally occurs in workers who have been exposed for several hours to airborne concentrations that do not produce discomfort during the exposure itself. The visual effect produced by such exposures consists of the appearance of colored haloes around lights, an effect that is caused by the diffraction of light through the swollen epithelial cells of the eye. Visual haloes are severely distracting and restrict activity substantially, and the mechanism underlying this effect is not well understood (Grant 1986/Ex. 1-975).

Lens effects. The lens is a transparent, avascular tissue surrounded by a thin, collagenous capsule. The major portion of the lens is composed of long, thin fibers that form closely packed, onionlike layers. Transparency is dependent on several factors: a highly ordered cellular arrangement; fiber size, shape, and uniformity; molecular structure; and regularity of fiber packing (Potts 1986/ Ex. 1-174). Interference with lens metabolism, with transport across cell boundaries, or with the integrity of the lens capsule itself can cause a loss of lens transparency and lead to decreased visual acuity (Potts 1986/Ex. 1-174). All such changes in lens transparency are referred to as cataracts.

Retinal effects. The retina is a compact neural structure that is responsible for converting the ocular light image to neural impulses. Because the retina is an internal structure, it is not generally affected by exposure to dust, splashes of liquids, or vapors. However, exposure to certain internally absorbed substances, such as methyl alcohol, may cause changes or lesions in the retina, including retinal edema or hemorrhage. Exposure to a few of the substances in this group can cause acute narrowing of the retinal arteries themselves, which can lead, in turn, to damage of the optic nerve and loss of

Effects on ganglion cell layer and optic nerve. Below the retinal surface layer lies the ganglion cell layer, which is composed of the cell bodies of neurons that extend to the midbrain via the optic nerve. Ganglion cells may be damaged directly when a chemical acts on the cell bodies themselves or secondarily when a toxin destroys the optic nerve. Depending on the severity of the exposure, loss of visual acuity or vision may ensue.

Dose-Response Relationships and Ocular Effects

For most of the chemicals shown in Table C5-1, limits have been proposed on the basis of research in animals, health surveys, and case reports of injuries occurring in occupationally exposed populations. These studies indicate that exposures to concentrations of these substances at . levels above the no-observed-effect level cause pain and may damage the eyes of exposed workers. For some of these substances, the available human data are limited, and evidence from animal studies or knowledge of a chemical's structural analogy to another chemical known to have ocular effects provides the basis for the proposed exposure limit. Animal models are generally good predictors of ocular effects in humans because the eyes of rodents, especially those of guinea pigs and rabbits, closely resemble human eyes. Thus, animal studies on the effects of chemical exposure on the eye can be relied on to predict accurately how the chemicals that produce these effects in animals will behave in workers exposed in industrial situations. For the seven chemicals in this group of ocular toxins. the available toxicologic data and OSHA's preliminary findings are described below.

N-ETHYLMORPHOLINE CAS: 100-74-3; Chemical Formula: C₆H₁₃NO H.S. No. 1172

In construction, shipyards, marine terminals, and long-shoring, the current OSHA PEL for N-ethylmorpholine is 20 ppm as an 8-hour TWA, with a skin notation. OSHA has no PEL for this substance in agriculture, and NIOSH has no REL. OSHA is retaining the skin notation and proposing an 8-hour TWA PEL of 5 ppm for this substance in construction, maritime, and agriculture. The proposed PEL and skin notation are consistent with the current ACGIH TLV* for N-ethylmorpholine; in the prior rulemaking, NIOSH concurred (Ex. 8-47. Table N1) that this limit and notation were appropriate. Promulgation of this PEL for N-ethylmorpholine would make

the PEL for this substance consistent across all OSHA-regulated sectors.

N-Ethylmorpholine is a colorless, flammable liquid with an ammonia-like odor; it is used as a catalyst in urethane manufacture, an intermediate in the production of dyestuffs, pharmaceuticals, rubber accelerators, and emulsifiers, and as a solvent in many applications (HSDB 1990).

N-Ethylmorpholine's acute toxicity in animals is relatively low; the oral LD50 in rats is 1780 mg/kg, and the LC50 in mice is 18,000 mg/m 3 for 2 hours (RTECS 1990). However, the vapors of this substance have high toxicity for the eye (Smyth, Carpenter, Weil, and Pozzani 1954). When N-ethylmorpholine was instilled into rabbit eyes, it caused the cornea to become hazy within 5 minutes and the epithelium covering the eye to slough off (Smyth, Carpenter, Weil, and Pozzani 1954). The injury to rabbits' eyes caused by Nethylmorpholine was graded 7 on an ascending severity scale of 1 to 10 (Smyth, Carpenter, Weil, and Pozzani

Overexposure to fairly low concentrations of the vapors from this substance causes corneal edema, bluegray vision, and colored haloes, as well as irritation of the eyes, skin, mucous membranes, and upper respiratory tract. Typically, vision becomes misty and haloes appear a few hours after workers have been exposed to Nethylmorpholine vapors for a period of hours. Distortion of vision can occur even at levels considerably lower than those that cause irritation [Mastromatteo 1965/Ex. 1–146].

Reversible corneal edema has been observed in workers exposed to 40 ppm or more of N-ethylmorpholine for several hours (Dernehl 1968). Workers routinely exposed to 3- to 4-ppm concentrations but never to concentrations above 11 ppm complained of haloes and foggy vision as well as drowsiness (ACGIH 1986/Ex. 1-3, p. 263). The irritant effects of Nethylmorpholine were also seen in a controlled-exposure experiment involving volunteer subjects. Ten volunteers exposed for 2.5 minutes to a concentration of 100 ppm experienced irritation of the eyes, nose, and throat: those exposed for 2.5 minutes to a 50ppm concentration experienced slight irritation; and no irritation was reported after exposure for 2.5 minutes to 25 ppm (ACGIH 1986/Ex. 1-3, p. 263).

OSHA's current 20-ppm PEL for Nethylmorpholine in construction and maritime is not adequate to protect exposed workers against the occurrence of corneal edema and other adverse visual effects. Because corneal edema is both painless as it is developing and does not manifest symptoms for several hours after exposure, workers are likely to be unaware of the danger of exposure. This lack of warning properties is particularly hazardous because the effects on visual function of repeated exposure of the eyes to substances that cause corneal edema are not known.

Based on this evidence, OSHA preliminarily finds that the proposed PEL of 5 ppm as an 8-hour TWA is necessary to protect workers in construction, maritime, and agriculture from N-ethylmorpholine's injurious effects on the eyes. In addition, the Agency is retaining the skin notation because this substance can be absorbed through the skin in systemically toxic amounts (Genium MSDS 1986, No. 589). OSHA believes that the proposed PEL is necessary to reduce the significant risk of material health impairments, which are manifested as corneal edema, visual distortion, and other adverse visual effects, that are associated with occupational exposure to this substance. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

HYDROGEN SULFIDE CAS: 7783–06–4; Chemical Formula: H₂S H.S. No. 1209

OSHA's current limit for hydrogen sulfide in construction and maritime is 10 ppm as an 8-hour TWA; there is no PEL for this substance in agriculture. The ACGIH TLV®s for hydrogen sulfide are 10 ppm as an 8-hour TWA and 15 ppm as a 15 minute STEL; NIOSH has a 10-ppm, 10-minute REL for this substance. OSHA is retaining the 8-hour TWA of 10 ppm in construction and maritime and proposing to add a STEL of 15 ppm in these two sectors; the Agency is also proposing to extend both the 8-hour TWA and the STEL to agriculture. Promulgation of these PELs will make OSHA's limits for hydrogen sulfide consistent across all regulated

Hydrogen sulfide is a colorless, flammable gas with the odor of rotten eggs. It is widely used as a chemical intermediate, an analytical reagent, and in the manufacture of heavy water in the utilities sector. In agriculture, it is used as a disinfectant (HSDB 1985). It is also generated inadvertently by the fermentation of animal manure. Many farm workers have been exposed to this substance while working in the vicinity of liquid manure storage pits and have been asphyxiated as a consequence (Osbern and Crapo 1981). Hydrogen sulfide also is encountered in natural oil

and gas deposits and in sewers, caissons, tunnels, and other construction sites (Grant 1986, p. 495). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Hydrogen sulfide's effects on experimental animals are similar to those seen in exposed workers: conjunctivitis, pulmonary irritation. acute poisoning, and death by chemical asphyxiation (Klaassen, Amdur, and Doull 1986, p. 242; Grant 1986, p. 496). The LC₅₀ in mice is 673 ppm for 1 hour (RTECS 1990). A number of experiments have demonstrated that exposure to hydrogen sulfide concentrations of 50 to 100 ppm for several hours (or sometimes longer) causes damage to the corneal epithelium of dogs, cats, rabbits, and guinea pigs; animals are believed to be somewhat less sensitive than humans to hydrogen sulfide's ocular effects but may be more sensitive to its pulmonary effects (Grant 1986, p. 496).

When inhaled at concentrations exceeding 500 ppm, exposure to hydrogen sulfide has caused respiratory paralysis and death. Acutely poisoned individuals who recover may experience headaches, fatigue, dizziness, and nystagmus; eventually, however, recovery is usually complete (Milby 1962; NRC 1979). The 1986 ACGIH Documentation (Ex. 1-3, p. 318) cites several reports (Brieger 1964; Kranenburg and Kessener 1935; Masure 1950, in Carson 1963; Elkins 1950a/Ex. 1-953) of the occurrence of adverse ocular effects, including conjunctivitis, caused by exposure to 20 ppm or less of hydrogen sulfide. A study by Poda and Aiken (1966/Ex. 1-115) reports that the adoption of a voluntary limit of 10 ppm in two heavy-water plants eliminated exposure problems at those facilities. An early study by Flury and Zernik (1931f) reports that the conjunctivitis caused by the exposure of volunteers to 10 to 15 ppm of hydrogen sulfide for six hours endured for several days; however, this substance is not known to have caused irreversible eye damage.

In the earlier Air Contaminants rulemaking, OSHA received several comments related to the health effects and proposed limits for hydrogen sulfide (Exs. 3–1163, 3–216, 8–37, 8–47, 129; Tr. XI, pp. 114, 225). One commenter, the Edison Electric Institute (EEI) (Tr. XI, p. 225), described the exposures of utility workers to hydrogen sulfide, and another, the Montana Sulphur and Chemical Corporation (Ex. 3–216), stated that, in its opinion, the evidence for the proposed limits was not "compelling."

Because Montana Sulphur and Chemical itself had never, in its long experience of manufacturing and handling this "notoriously toxic" substance, had a case of eye irritation that required medical treatment, it urged OSHA (Ex. 3–216) to promulgate a STEL for hydrogen sulfide in the range of 25 to 30 ppm rather than at the proposed level of

In response to this commenter, OSHA noted (54 FR 2494) that the proposed STEL of 15 ppm was based on the best available evidence (i.e., a report that workers exposed to this substance at this level had not experienced eye irritation, while workers exposed to higher levels had experienced such effects), as well as reports in the industrial hygiene literature that levels below 20 ppm cause eye irritation (Brieger 1964; Kranenburg and Kessener 1935; Masure 1950, in Carson 1963; Elkins 1950a/ Ex.1-953). For example, the author of the best-known general source on the toxicology of the eye (Grant 1986) states that "where the concentration [of hydrogen sulfide] is regularly kept below 10 ppm in air, it is rare to have any irritation of the eyes" (p. 496). OSHA believes that the proposed STEL will ensure that concentrations are maintained close to the 8-hour TWA and that excursions above irritant levels are thus minimized.

Based on this evidence, OSHA preliminarily finds that the current 10ppm 8-hour TWA limit alone does not adequately protect workers in construction and maritime against the adverse ocular effects associated with exposure to concentrations of hydrogen sulfide above 10 ppm. Furthermore, agricultural workers are not presently protected by any limit. OSHA believes that the eye irritation and conjunctivitis associated with such exposures represent a significant risk of material health impairment to workers in construction, maritime, and agriculture because these workers may experience pain and other ocular effects and be forced to seek medical treatment after such exposures. OSHA is accordingly retaining the 8-hour TWA limit of 10 ppm for hydrogen sulfide in construction and maritime and is proposing to establish a short-term limit of 15 ppm in these two sectors. The Agency is also proposing to extend both limits to agriculture. The Agency preliminarily finds that these limits are necessary to provide protection from the significant risk of exposure-related ocular effects, including conjunctivitis, corneal edema, and distortion of vision, associated with occupational exposure to hydrogen sulfide. In addition, promulgation of

these limits will make OSHA's PELs for this substance consistent across all regulated sectors. HYDROQUINONE CAS: 123-31-9; Chemical Formula: C₆H₄(OH)₂

H.S. No. 2094
OSHA's current limit for hydroquinone in general industry, construction, and maritime is 2 mg/m³ as an 8-hour TWA. The Agency has no PEL for hydroquinone in agriculture. The ACGIH TLV*-TWA for this substance is 2 mg/m³, and the NIOSH REL is 2 mg/m³ as a 15-minute ceiling. OSHA is proposing a PEL for hydroquinone of 2 mg/m³ as an 8-hour TWA in agriculture. Promulgation of this limit will make the PEL for hydroquinone consistent across all OSHA-regulated sectors.

Hydroquinone is a white, crystalline solid that is used primarily in photographic developers. It is also used as an antioxidant or stabilizer in polymers, oils, fuels, and paints, and as a dye intermediate. Hydroquinone derivatives are reported to be effective antimitotic and tumor-inhibiting agents (ACGIH 1986, p. 319; Clayton and Clayton 1981, p. 2589).

Exposure to hydroquinone causes skin and eye irritation, skin depigmentation, respiratory symptoms, and ocular damage. The oral LD50 in rats is 320 mg/ kg; the dermal LD50 in an unspecified species of mammal is 5970 mg/kg (RTECS 1990). Before death, acutely poisoned animals exhibit an increase in motor activity, an increase in the formation of methemoglobin, hypersensitivity to external stimuli, labored breathing, hyperactive reflexes, and cyanosis. These initial signs of poisoning are followed by clonic convulsions, exhaustion, loss of reflexes, lowered body temperature, paralysis, coma, and death (Clayton and Clayton 1981, p. 2590). Pigment accumulation in the conjunctiva and cornea has been induced in rabbit eyes after 2 to 4 months of daily application of powdered hydroquinone to the eyes. Scarring and gray opacification were also noted in this study (Grant 1986, p. 499).

Industrial exposure to hydroquinone occurs during the manufacture and use of this substance and involves not only the dust of hydroquinone but its vapor. Acute exposure both to quinone and hydroquinone causes conjunctival irritation. In a study of workers manufacturing hydroquinone, eye injuries developed gradually over a period of years in workers exposed for fewer than 5 years. Although quinone was probably the main cause of these injuries, hydroquinone was considered a contributory cause. No systemic effects

were associated with these exposures (Anderson and Oglesby 1958; Sterner, Oglesby, and Anderson 1947). Skin irritation, allergic sensitization, depigmentation, and dermatitis have reportedly occurred following repeated skin contact with creams containing 5 percent or more hydroquinone (NIOSH 1978).

A group of 24 workers in a Swedish movie film laboratory who used hydroquinone-containing and other color film developing agents developed occupational dermatitis. Patch testing confirmed that hydroquinone was the allergenic agent in one of these workers (Liden, Brehmer-Andersson 1988). Another photography laboratory worker developed vitiligo (depigmentation of the skin) caused by hydroquinone. This worker had been dipping x-ray films into hydroquinone with his bare hands for 10 years before he developed this condition (Das and Tandon 1988).

Chronic exposure to quinone vapor and hydroquinone dust causes a brownish discoloration of the conjunctiva and cornea, small opacities of the cornea, and structural changes of the cornea that result in the loss of visual acuity. The structural corneal damage consisted of changes in the curvature of the lens; such curvature can lead to progressive loss of visual acuity and blindness (Anderson and Oglesby 1958; Sterner, Oglesby, and Anderson 1947). Exposure to hydroquinone dust concentrations as high as 20 to 30 mg/m3 produced no systemic effects, and volunteers showed no signs of toxicity after ingesting 300 to 500 mg hydroquinone daily for up to 5 months (Carlson and Brewer 1953; Sterner, Oglesby, and Anderson 1947). In addition to ocular and skin effects, exposure to hydroquinone causes respiratory symptoms. Thirty-three workers exposed to hydroquinone, trimethyl hydroquinone, and retinenehydroquinone, in a chemical plant showed a higher prevalence of respiratory symptoms than unexposed workers from the same plant, and the exposed group also showed significantly lower pulmonary function values. Because these workers had significantly higher levels of immunoglobulin G and elevated levels of immunoglobulin E compared to in-plant controls, the authors concluded that exposure to hydroquinone causes ventilatory impairment, perhaps by an immunological mechanism (Choudat, Neukirch, Brochard, Barrat, Marsac, Conso, and Philbert 1988).

Based on this evidence, OSHA is proposing a 2 mg/m³ 8-hour TWA limit to protect workers in agriculture from the significant risk of skin and respiratory irritation, skin depigmentation, and ocular damage associated with exposure to hydroquinone. OSHA considers these effects material impairments of health and preliminarily concludes that this limit is necessary to substantially reduce the significant risk of these impairments in exposed agricultural workers. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

METHYL ALCOHOL

CAS: 67-56-1; Chemical Formula: CH₈OH

H.S. No. 1252

OSHA's current 8-hour TWA limit for methyl alcohol in construction and maritime is 200 ppm as an 8-hour TWA. There is no PEL for this substance in agriculture. The ACGIH TLVs* for methyl alcohol are an 8-hour TWA of 200 ppm, a STEL of 250 ppm, and a skin notation. The NIOSH REL for methyl alcohol is 200 ppm as a TWA and 800 ppm as a STEL; however, after reviewing the health evidence for methyl alcohol, NIOSH concurred (Ex. 8-47, Table N1) with the PEL OSHA is proposing. OSHA is retaining the 8-hour TWA PEL of 200 ppm in construction and maritime, proposing to add a STEL of 250 ppm for this substance in these two sectors, and additionally proposing both limits in agriculture. In addition, OSHA is proposing to add a skin notation to the limit for methyl alcohol.

Methyl alcohol is a mobile, highly polar, flammable liquid that is widely used as an industrial solvent in enamels, paints, stains, varnish removers, cleaners, and antifreezes (Clayton and

Clayton 1982, p. 4529).

Methyl alcohol has severe ocular effects in animals, both when in contact with the eye itself and when ingested. The oral LDso in rats is 5628 mg/kg, and the LDso in the same species is 64,000 ppm for 4 hours (RTECS 1990). The dermal LD50 in rabbits is 15,800 mg/kg (RTECS 1990). Three of six rabbits developed a moderate degree of corneal opacity when undiluted methyl alcohol was instilled into their eyes, and all six animals developed conjunctivitis as a result of eye contact with the liquid (Clayton and Clayton 1982, p. 4531). Dogs killed by the inhalation of acute doses of methyl alcohol (37,000 ppm for 8 hours) showed, at autopsy, hyperemia of the choroid and edema of the ocular tissue, as well as early signs of retinal degeneration (Tyson and Schoenberg 1914). Methyl alcohol has also been shown to have embryotoxic. developmental, and reproductive effects in animals of several species. In monkeys, the lowest lethal concentration by inhalation is 1000 ppm and the lowest lethal dermal dose is 393

mg/kg (RTECS 1990).

Workers exposed to methyl alcohol at concentrations between 200 and 375 ppm experience severe recurrent headaches and, at higher levels, the visual capacity of exposed individuals is diminished. The lowest reported lethal concentration in humans is 868 mg/kg (RTECS 1990). The metabolites believed to be chiefly responsible for methyl alcohol's toxic effects are formic acid and formaldehyde, which cause acidosis (Rom 1983, p. 523). If the poisoning is severe, impairment of vision and death may occur; these effects have occurred after severe ingestion, inhalation, and dermal absorption (NIOSH 1976; Henson 1960). Chronic exposure to airborne concentrations of methyl alcohol of 1200 to 8300 ppm can cause impaired vision (NIOSH 1976). Splashed into the eyes, methyl alcohol causes reversible corneal injury; in prolonged contact with the skin, it causes defatting, scaling, and dermatitis (NIOSH 1976).

In the prior rulemaking, several commenters submitted information to the record on methyl alcohol (Exs. 150, 194, 3-661, 3-902, and 3-896). Both the Eastman Kodak Company (Ex. 3-661) and the Chevron Corporation (Ex. 3-896) objected to the STEL of 250 ppm because they believe that no STEL is warranted for methyl alcohol. However, OSHA rejected the reasoning of these commenters (see 54 FR 2495), noting that, in addition to those studies specifically cited in the preamble, many other studies report that exposure to methyl alcohol at levels that cause headaches is possible even when the 8hour limit of 200 ppm is being observed.

Based on this evidence, OSHA preliminarily finds that the proposed 250-ppm STEL is necessary because the current 8-hour PEL of 200 ppm alone cannot protect workers in construction, maritime, and agriculture from exposure to short-term peaks at levels that cause eye irritation and severe, recurrent headaches. OSHA is proposing to add a skin notation to the PEL for methyl alcohol because a dermal dose of only 393 mg/kg has caused death in monkeys; this dose is well below the dermal LD50 of 1000 mg/kg adopted by OSHA as the cutoff for skin designations (see Section C.15 of this preamble) [RTECS 1990]. The Agency preliminarily concludes that the proposed 8-hour TWA and 15minute STEL will together reduce the significant risk of headaches and blurred vision presented by short-term occupational exposures to methyl alcohol at concentrations above these

levels. In addition, the proposed skin notation will reduce the likelihood that exposed workers in construction, maritime, and agriculture will experience the systemic toxicity caused by absorption of this substance through the skin that has been demonstrated to occur in experimental animals. The Agency preliminarily finds that the headaches, blurred vision, other ocular effects, and systemic toxicity associated with exposure to methyl alcohol constitute material impairments of health. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

METHYL SILICATE
CAS: 681-84-5; Chemical Formula:
(CH₃O)₃Si
H.S. No. 1266

OSHA currently has a ceiling limit of 5 ppm for methyl silicate in construction and maritime; there is no PEL for this substance in agriculture. The ACGIH TLV* for this substance is 1 ppm as an 8-hour TWA. OSHA is proposing an 8-hour TWA PEL of 1ppm for workplaces in construction, maritime, and agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) that this limit, which was recently established in general industry, is appropriate.

Methyl silicate is a colorless liquid or a crystalline solid. It is used as an intermediate and to coat television tubes.

The toxic action of methyl silicate has been compared to that of mustard gas, both in terms of severity and the delayed onset of signs and symptoms (Grant 1986, p. 627). When a single drop of methyl silicate was placed into the eye of a rabbit, the resulting injury was graded 9 out of a possible 10 on an ascending scale of severity (Grant 1986, p. 627). The corneal epithelium of the eye of the rabbit became permanently opacified (Grant 1986, p. 627). -Rabbits exposed to 1000 ppm of methyl silicate in dry air experienced delayed eye burns (ACGIH 1986/Ex. 1-3, p. 409). Exposure of these animals to a methyl silicate concentration of approximately 15,000 ppm for five minutes caused eye burns, but exposure to this level for four minutes caused no appreciable effect. Guinea pigs showed maximum no-effect levels of 135 ppm for 15 minutes, 90 ppm for one hour, and 20 ppm for 8 one-hour periods. The latency period for ocular changes was 16 hours for serious effects and up to three days for mild involvement (ACGIH 1986/Ex. 1-3, p.

It is estimated that exposing humans to methyl silicate at concentrations of

200 to 300 ppm for 15 minutes will produce ocular lesions and that exposure to 1000 ppm for this period will produce injury requiring hospitalization (ACGIH 1986/Ex. 1-3, p. 409). There is one report of blindness caused by a splash of this substance into the eyes (Grant 1986, p. 628).

Based on this evidence, OSHA preliminarily concludes that the proposed 8-hour TWA limit of 1 ppm is necessary to protect workers in construction, maritime, and agriculture from the ocular effects associated with exposure to this substance. The basis for OSHA's reasoning is that evidence has shown that (1) exposures of 200-300 ppm for 15 minutes produce only mild eye effects in humans (ACGIH 1986/Ex. 1-3, p. 409) and (2) that exposure to a concentration of 90 ppm for 1 hour, or to 20 ppm for 8 one-hour periods, produces no damage to the eyes of guinea pigs. The proposed 8-hour TWA PEL of ppm, which is more than a factor of 20 below the lowest-observed-effect level, will ensure that workers in construction. maritime, and agriculture are protected from the significant risks of such material health impairments. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

NAPHTHALENE

CAS: 91-20-3; Chemical Formula: C10H8 H.S. No. 1282

OSHA's current exposure limit for naphthalene in construction and maritime is 10 ppm as an 8-hour TWA. The proposal retains this TWA, proposes to add a short-term limit of 15 ppm, and additionally proposes to extend both the TWA and the STEL to agriculture. These limits agree with the ACGIH's TLV*s. There is no limit in agriculture. NIOSH has no REL; however, in the prior rulemaking, NIOSH (Ex. 8-47, Table N1) concurred with the PELs selected by OSHA for this substance, which are those recently established in general industry.

Naphthalene is a white, crystalline substance that imparts the characteristic "moth-ball" odor to commercial mothball products (HSDB 1985). Naphthalene is an important chemical intermediate that is also used in dyes, explosives, lubricants, tanning agents, and pesticides (HSDB 1985).

In animals, naphthalene causes hemolysis (destruction of the red blood cells), tumors of the blood, and developmental effects (RTECS 1990), as well as ocular toxicity (Grant 1986). Cataracts and severe eye irritation have been induced in experimental animals by administration of this substance

(Grant 1986). The oral LDso in rats is 490 mg/kg (RTECS 1990).

In humans, the inhalation of naphthalene vapor causes eye irritation, headache and nausea (Proctor, Hughes, and Fischman 1988, p. 358). The lethal dose in humans has been reported as 50 mg/kg (NIOSH 1977i/Ex. 1-1182). In contact with the eye, naphthalene causes conjunctivitis, corneal injury, chorio-retinitis, scotoma, and decreased visual acuity (Proctor, Hughes, and Fischman 1988, p. 358). Eight of 21 workers exposed to unspecified levels of naphthalene for 5 years developed opacities of the lens of the eye (Grant 1986). Ingestion of large amounts of naphthalene causes severe hemolytic anemia and hemoglobinuria (Stokinger and Mountain 1963/Ex. 1-765). Exposure to a 15-ppm concentration of the vapor is reported to cause marked eye irritation (Grant 1986).

In the prior rulemaking, the American Iron and Steel Institute commented that, in its opinion, no STEL was warranted for naphthalene. OSHA responded (54 FR 2496) to this comment by pointing to the study by Robbins (1951/Ex. 1-799). which clearly shows that excursions as high as 15 ppm cause severe eve irritation and concluded that the proposed STEL was thus both necessary and appropriate.

Accordingly, OSHA is retaining the 8hour TWA of 10 ppm in construction and maritime, proposing to add a 15minute STEL of 15 ppm in these sectors, and proposing to extend both PELs to agriculture. The Agency preliminarily concludes that these limits will protect workers in construction, maritime, and agriculture from the significant risks of eye irritation and cataracts, which constitute material health impairments that are potentially associated with exposure to levels above the current limit. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

OUINONE CAS: 106-51-4; Chemical Formula:

CeH4O2

H.S. No. 2138

In general industry, construction, and maritime, OSHA's permissible exposure limit for quinone is 0.5 ppm as an 8-hour TWA. There is no limit for this substance in agriculture. The ACGIH has a current TLV®-TWA limit of 0.1 ppm for this substance. NIOSH has no REL but concurs (EX. 8-47, Table N3A) with the limit being proposed. OSHA is proposing to establish a PEL of 0.1 ppm for quinone in agriculture. Promulgation of this limit will make the PEL for this

substance consistent across all OSHAregulated sectors.

Quinone is a yellow crystalline solid with a penetrating, chlorine-like odor. This substance is used as an intermediate in the manufacture of fungicides, hydroquinone, and dyes, in photography, and as an oxidizing agent and analytical reagent (ACGIH 1986, p. 509; Hawley's 1987, p. 991).

Quinone causes severe eye and skin irritation in humans; in animals it causes lung and kidney damage and convulsions. The oral LDso in rats is 130 mg/kg (RTECS 1990). Large oral or subcutaneous doses of quinone cause local irritation, convulsions, respiratory difficulty, a decrease in blood pressure, and death due to paralysis of the medullary centers (Clayton and Clayton 1981, p. 2593). A major cause of death in acutely poisoned animals is asphyxia due to pulmonary damage and quinone's effects on hemoglobin (Deichman and Keplinger 1963, in Clayton and Clayton 1981, p. 2593). Signs of kidney injury have also been observed in severely poisoned animals (Deichman and Keplinger 1963, Clayton and Clayton 1981, p. 2593). Quinone has been tested for carcinogenicity in mice by skin application and inhalation and in rats by subcutaneous injection. The International Agency for Research on Cancer (IARC) has concluded, however. that the evidence in animals is insufficient to evaluate quinone's carcinogenicity (IARC 1977, Vol. 15, p.

Quinone causes ocular and cutaneous lesions in humans; however, no cases of systemic poisoning have been reported. In contact with the skin, quinone causes discoloration, severe irritation, erythema, swelling, and papules and vesicles; prolonged contact can cause necrosis of the skin (Clayton and Clayton 1981, p. 2594). Eye irritation becomes noticeable on exposure to concentrations above 0.1 ppm; acute exposures cause conjunctival irritation. corneal edema, ulceration, and scarring (AIHA Hygienic Guide Series 1978). Exposure to quinone vapor produced characteristic chronic injuries in workers in a hydroquinone manufacturing facility. The effects of exposure developed gradually; no serious effects occurred in individuals exposed to the vapor for less than 5 years. Signs and symptoms in those exposed for longer than 5 years included pigmentary changes of the conjunctiva and cornea, corneal opacities, and loss of visual acuity (Sterner, Oglesby, and Anderson 1947). Although the pigmentary changes induced by quinone are reversible, the other ocular effects

caused by exposure to this substance sometimes progress even after exposure has ceased (Proctor, Hughes, and Fischman 1988, p. 431).

Based on this evidence in humans and animals, OSHA preliminarily concludes that exposure to quinone causes severe skin and eye injury, as well as pulmonary damage. The Agency believes that, in the absence of a limit, workers in agriculture are at risk of experiencing quinone's adverse effects and that establishing an 8-hour TWA of 0.1 ppm for quinone in agriculture is necessary to reduce these risks of material health impairment.

Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Preliminary Conclusions. OSHA
believes that adoption of the limits being
proposed for this group of chemicals,
which have the potential to cause
adverse ocular effects ranging from
transient discomfort to permanent
blindness, will substantially reduce the
risk of visual impairment associated
with exposure to these substances. The
toxicological bases for the proposed
limits include evidence derived from
occupationally exposed workers and
results obtained in animal models that

have been shown to be excellent predictors of human responses. The risks being protected against have serious consequences, both in terms of the health and functional capacity of the exposed workers themselves and the safety and well-being of these workers and their co-workers.

The available health evidence for the substances described in this section forms a reasonable basis for proposing the revision or addition of these limits. At the time of the final rule, OSHA will promulgate new or revised limits for these substances if the Agency determines that these limits will reduce significant risk. Promulgation of the proposed limits will also make OSHA's limits for these substances consistent across all regulated sectors.

6. Substances for Which Proposed Limits Are Based on Avoidance of Respiratory Effects

Introduction. For workplaces in construction, maritime, and agriculture, limits are being proposed for a total of 44 substances or materials for which exposure has been shown to cause adverse respiratory effects. The substances in this group cause acute pulmonary edema, alveolar damage, or

chronic respiratory damage through the general mechanisms of cellular damage or fibrosis. At sufficient doses, these effects can be permanent, disabling, and life-threatening.

Some of the materials in this group are composites of naturally occurring minerals; for these substances, the Agency is proposing limits based on the most hazardous component. For several materials (coal dust, crystalline tripoli, silica, and graphite), OSHA is proposing that the TWA be measured as the respirable quartz fraction of the dust, because it is exposure to this fraction that presents the greatest risk to exposed workers in these sectors.

Table C6-1 lists the substances in this group, along with their current PELs in construction and maritime and their CAS and HS numbers. The 1987-1988 TLV*s, NIOSH RELs, and limits being proposed for these substances in construction, maritime, and agriculture are also shown on Table C6-1. With the exception of limits for asphalt fumes, fibrous glass, and mineral wool, the limits being proposed are those in effect in general industry. For these three substances, OSHA is proposing PELs in general industry as well as in construction, maritime, and agriculture.

Table C6-1.—Substances for Which Proposed Limits Are Based on Avoidance of Respiratory Effects

U.S. No /chomical game CAS No PEL in		construction and	1967-1988 ACGIH TLV* ** NIOSH REL*		Proposed OSHA PEL in construction, maritime, and agriculture*
1017 Aluminum (pyro powders)	7429-90-5		5 mg/m³ TWA		57774 mg/m² TWA.

** OSHA's PELs do not currently apply in agriculture; OSHA's TWA limits are for 8-hour exposures; its STELs are for 15 minutes unless otherwise specified; and its ceilings are peaks not to be exceeded for any period of time.

** The ACGIH TLV*-TWA is for an 8-hour exposure; its STELs are 15-minute limits not to be exceeded more than 4 times in any working day, with a minimum of 60 minutes between successive STEL exposures; and its ceilings are peaks not to be exceeded for any period of time.

*** NIOSH TWA limits are for 10 hour/day, 40 hour/week exposures unless otherwise specified, and its ceilings are peaks not to be exceeded for any period of time unless a duration is specified in parentheses.

+ NIOSH considers this substance a potential occupational carcinogen.

Description of the Health Effects. The respiratory system is a major route of occupational exposure for toxic substances. Because of the vital nature of pulmonary function, respiratory toxicants present a serious health hazard both from acute and chronic exposures. Acute respiratory disease can be life threatening.

Chronic pulmonary disease can result from long-term exposure to respiratory toxicants and is potentially crippling because it greatly reduces the quality of life and the productivity of its victims. In addition, the onset of respiratory disease can be insidious, because it may be indicated only by the gradual

development of a few nonspecific signs (Petersdorf et al. 1983).

The difficulties of detecting irreversible respiratory effects complicate the prevention of pulmonary disease. Pulmonary function can be evaluated with a variety of tests. including measurements of the vital capacity and of resting and forced expiratory volumes. However, certain conditions, including emphysema and fibrosis, are difficult to diagnose even with such tests. In addition, these same diseases often continue to progress even after the affected individual has recognized the problem and obtained medical assistance; also, respiratory effects may worsen even after exposure

has ceased, which makes prevention even more vital. In addition to the threat posed to the general occupational population by respiratory toxins, certain subpopulations, such as persons with impaired lung function caused by asthma, bronchitis, emphysema, or pulmonary fibrosis, are at special risk from the adverse effects of exposure to these substances. Tobacco smoking can cause or aggravate all of the respiratory conditions discussed above and can interact additively or synergistically with respiratory toxins to increase their adverse effects on the pulmonary system. For example, tobacco smoking acts additively with coal dust to diminish pulmonary function. Because

tobacco smoke contains nitrogen oxides. cadmium, and ammonia, occupationally exposed workers who smoke have an additional source of exposure to these respiratory toxins.

Two general categories of lung injuries are relevant to the group of substances under consideration:

· Damage to cells lining the airways. which results in necrosis (localized areas of dead cells), increased permeability, and edema.

· Production of fibrosis, which may become massive and greatly reduce lung

capacity.

Cellular damage resulting in edema and emphysema. A number of substances cause damage to cells lining the airways. This can result in increased permeability of cell membranes and subsequent edema, hemorrhage, and localized necrosis (areas of dead cells). Chronic inhalation of certain chemicals causes destruction of the alveolar septa and results in emphysema. Cellular damage may be either localized or diffuse, depending on the distribution of the toxicant in the lung.

Edema is the release of fluid into the lumen (open spaces of the airways) or alveoli. Serious edema can take several hours to develop so that, in some cases, life-threatening or even fatal exposures can take place without the individual's being aware at the time of exposure of the extent of the damage. Ozone, nitrogen dioxide, and paraquat all cause localized cellular damage leading to edema (Klaassen, Amdur, Doull et al. 1986/Ex. 1-99).

Fatalities from pulmonary edema have resulted from exposures to concentrations of nitrogen dioxide of about 200 ppm (Sax 1984). Paraquat is unusual in that it can cause delayed pulmonary damage following exposure. even when exposure occurs via routes other than inhalation (Klaassen, Amdur,

Doull et al. 1986/Ex. 1-99).

Necrotic changes can reduce the functional surface area of the lung. One type of lesion often noted in persons exposed to respiratory toxins is benign granulomas, which are localized masses formed when the immune system attempts to sequester a foreign object. Depending on the extent of the damage, these masses may reduce the functional capacity of the lung. Exposure to selenium-doped bismuth telluride has been associated with the production of benign granulomas without fibrosis (Wagner, Madden, Zimber, and Stokinger 1974, as cited in ACGIH 1986/ Ex. 1-3, p. 59).

Emphysema is caused by a gradual destruction of the cells of the alveolar septa, which causes a loss of elasticity in the lung. A slight degree of emphysema is present in much of the adult population and does not cause any functional impairment. As the disease progresses, however, serious and lifethreatening reductions in functional capacity can occur. Once the disease has advanced to the point of serious functional impairment, it is, for the most part, irreversible (Petersdorf et al. 1983). There is evidence that a number of the substances in this group cause emphysema, including sulfur tetrafluoride (ACGIH 1986/ Ex. 1-3), ozone, and nitrogen dioxide (Klaassen, Amdur, Doull et al. 1986/Ex. 1-99).

Fibrotic changes. Pulmonary fibrosis was one of the earliest recognized forms of occupational disease. Fibrosis should be distinguished from pneumoconiosis, although these terms are often used interchangeably. Pneumoconiosis is a more general term indicating the presence of a foreign substance in the lungs, as determined by radiographic (Xray) analysis. This definition encompasses a variety of conditions and does not by itself necessarily indicate functional damage (Petersdorf et al. 1983). In contrast, fibrosis is a seriously

debilitating disease. One type of fibrosis is interstitial fibrosis, which is a kind of pneumoconiosis characterized by deposition of fibrous tissue in the interstitial spaces between the alveolar membrane and the pulmonary capillary membrane. Interstitial fibrosis greatly reduces the diffusing capacity of the lung and thus causes oxygen deprivation in the body (Guyton 1981/Ex. 1-1002). Like emphysema, fibrosis is largely irreversible; it sometimes progresses even in the absence of further exposure (Petersdorf et al. 1983).

Silicosis is a form of interstitial fibrosis that is caused by exposure to respirable silica particles (Klaassen, Amdur, Doull et al. 1986/Ex. 1-99). Exposure to coal dust causes a pneumoconiosis with fibrosis that can be severely debilitating (Petersdorf et al. 1983). In addition, exposure to graphite, mica, and grain dust have all been associated with fibrosis in workers

(ACGIH 1986/Ex. 1-3).

Dose-Response Relationships and Respiratory Effects. For most of the substances in this group, the proposed permissible exposure limits have been based on health surveys and case reports of occupationally exposed populations. In some cases, animal studies have provided the evidence of a substance's toxicity. As is the case for most of the substances for which OSHA is proposing new, reduced, or revised limits, the dose-response curve for respiratory irritants tends to be Sshaped. Table C6-2 presents doseresponse data on the adverse pulmonary effects of representative chemicals in this group, the populations exposed, and the endpoints observed. The substances on Table C6-1, and describe the nature of the risks faced by worers exposed to them in construction, maritime, and agricultural workplaces.

375 Sulfur dioxide	7446-09-5	5 ppm TWA	2 ppm TWA 5 ppm STEL	1 ppm	Humans	Accelerated loss of pulmonary function.
378 Sulfur tetrafluoride	7783-60-0		0.1 ppm Ceiling	4 ppm	Rats 4 hrs/ day/ 10 days	Emphysema, marked clinical signs of respi- ratory impairment.
409 Trimellitic anhydride	552-30-7		0.005 ppm TWA		Rats	Intra-alveolar hemorrhage. (No exposure duration indicated.)

^{*} OSHA's TWA limits are for 8-hour exposures; its STELs are for 15 minutes unless otherwise specified; and its ceilings are peaks not to be exceeded for any period of time.

N/A = Not available.

ALUMINUM (PYRO POWDERS) CAS: 7429-90-5; Chemical Formula: A1 H.S. No. 1017

OSHA has no permissible exposure limit for aluminum pyro powders in the construction, maritime, and agriculture industries. The ACGIH has an 8-hour TLV*-TWA of 5 mg/m³; NIOSH has no REL for these powders. The Agency is proposing an 8-hour TWA PEL of 5 mg/m³ for aluminum pyro powders in the construction, maritime, and agriculture industries; NIOSH (Ex. 8-47, Table N1) concurred with this limit when the Agency recently established it in general industry. Promulgation of this limit will make OSHA's PEL for these substances consistent across all OSHA-regulated sectors.

Aluminum in its elemental form is a white, malleable, ductile metal. Powder and flake aluminum are flammable and can form explosive mixtures in air. Aluminum pyro powders are used in fireworks and aluminum paint (Proctor, Hughes, and Fischman 1988, p. 66).

In addition to respiratory effects, aluminum pyro powders can cause gastrointestinal effects and eye irritation. Exposure to aluminum compounds can also affect the absorption of other substances such as calcium and iron compounds (Spencer et al. 1969, 1977). Particles of aluminum can cause necrosis of the cornea when deposited in the eye; in both rabbit and human eyes, aluminum particles have been shown to cause some local necrotic imprints in the fundus at the site of the absorbed particles (Fontana 1938; Jess 1924; Sanin 1947; Knave 1969]. Aluminum pyro powders are more acutely toxic than the metal dusts of aluminum (Stokinger 1981a/Ex. 1-1133). Several British studies have examined the effects of exposure to this finely flaked aluminum on workers employed in paint and pyrotechnics plants. Their findings revealed that pulmonary fibrosis may result from exposure to pyro powders, although epidemiologic evidence indicates that additives used to prevent oxidation and agglomeration

may have contributed to the incidence and nature of the disease (Edling 1961/ Ex. 1-733; Jordan 1961/Ex. 1-559; Mitchell, Manning, Molyneux, and Lane 1961/Ex. 1-564).

OSHA believes that an 8-hour TWA permissible exposure limit of 5 mg/m3 for aluminum pyro powders will prevent the significant risk of lung changes in workers exposed to such powders in construction, maritime, or agricultural operations. In the recent generalindustry rulemaking, the Agency determined that these lung changes constitute material impairments of health. Accordingly, OSHA believes that the proposed PEL is necessary to reduce the risk of these health impairments in workers in these sectors. In addition, promulgation of this limit will make OSHA's PEL for aluminum pyro powders consistent across all regulated sectors.

ASPHALT FUMES

CAS: 8052-42-4; Chemical formula: None H.S. No. 1028

There is no current OSHA PEL for asphalt fumes. In the Air Contaminants rulemaking, a PEL of 5 mg/m3 (8 hour TWA) for asphalt fumes measured as total particulate was proposed. Many comments were received by the Agency and the complexity of the issues at that time caused OSHA to delay rulemaking on this substance. The AFL/CIO, in the case of AFL/CIO vs. OSHA #89-7185 (11th Cir.) challenged OSHA's failure to issue an asphalt standard. OSHA stated to the Court that it intended to set an exposure limit for asphalt fumes for all sectors as part of the construction rulemaking.

In this rulemaking OSHA is also proposing a PEL of 5 mg/m3 total particulate for general industry, maritime, construction and agriculture. However, subsequent to the 1988 proposal, an extensive body of new scientific data has become available. This data and criticisms of it are presented and extensively analyzed below. Consequently, commenters should respond to the various studies and the regulatory alternatives which would be appropriate based on final conclusions as to these studies. The economic aspects of the various alternatives are presented in the Regulatory Impact Analysis.

Asphalt, also called bitumen, is a mixture of hydrocarbons that is produced by the evaporation of the lighter hydrocarbons from petroleum distillation and subsequent partial oxidation of the residue. Occupational exposure to asphalt fumes can occur during its manufacture or as a result of the secondary heating of asphalt in processes such as road building and repair, roofing and the coating of construction materials (Thayer et al, 1981).

OSHA is addressing the risk to those who are exposed to asphalt fumes in the course of their employment (e.g., roofers and pavers). OSHA has not studied the issue and does not have current information that exposures to the general population are sufficiently high to warrant concern. It is the fume released from the asphalt which is of concern, and it is the physical proximity of the workers to these fumes that makes occupational exposure hazardous. OSHA has requested submission of any additional exposure monitoring data including environmental data for airborne asphalt fume levels that occur some distance from the worksite. Further, OSHA is maintaining dialogue with the Environmental Protection Agency on this issue.

Among the issues raised in the earlier rulemaking regarding asphalt fumes

- 1. Whether asphalt fumes are similar to coal tar fumes;
- Which is the appropriate method of measurement of asphalt fumes, the benzene-soluble fraction or total particulate;
- 3. Irritant and other respirator effects of asphalt fumes;
- 4. Whether asphalt fumes are carcinogenic:
- 5. What is the proper PEL for asphalt fumes: and.
- 6. Whether the PEL determined on the basis of the health data is technologically and economically feasible.

OSHA requests comment on all these issues and all other issues which may be relevant to occupational regulation of asphalt fume. In the following discussion, OSHA discusses the studies and presents the views of various organizations. Final decisions will be reached only after consideration of all comments.

On the first issue, OSHA's preliminary view is that there are significant differences between petroleum-derived asphalt fumes and coal tar pitch volatile; in 1983, the Agency published a Federal Register notice making clear that the term "coal tar pitch volatile" (CTPV) and OSHA's CTPV standard do not apply to petroleum asphalt. It should be noted here that in the 1983 rulemaking in which asphalt fume was specifically excluded from the standard for coal tar pitch volatile, 48 FR 2768 January 21, 1983, NIOSH supported the continued inclusion of asphalt in the regulation of CTPV, noting the differences between the two substances but recognizing the need for worker protection against high concentrations of PAHs. OSHA notes that coal tar pitch volatile is more irritating than asphalt fume, however the two substances look the same, have the same consistency, contain some common components such as polycyclic aromatic hydrocarbons (PAHs), and have often been used in the same applications. OSHA requests comment on all aspects of this issue.

As for the second point, OSHA's proposed PEL is measured as "total particulate." Another view is that the benzene-soluble fraction is the more specific and thus more appropriate means of measuring asphalt fume and includes this method of determining exposure in the current proposed PEL. The Asphalt Institute (AI) has pointed to several studies which indicate anomalies in measurements using that technique. It has been suggested that the

anomalies are the result of the use of plastic filters and that use of glass fiber filters will solve this problem. OSHA requests comment on all aspects this issue.

It should be noted that there are a number of different types or fractions of asphalt. Some commenters have suggested that the type or fraction may be relevant in analyzing these studies.

Respiratory Effects. A very recent study (Norseth, Waage and Dale, 1991, Am J Ind Med, Vol. 20, No. 6, Acute Effects and Exposure to Organic Compounds in Road Maintenance Workers Exposed to Asphalt) attempted to quantify the levels at which a variety of types of irritant and other acute effects were reported as a result of exposure to asphalt fumes. The authors attempt to correlate the reporting of acute symptoms and exposure to organic compounds in a cohort of road maintenance workers. Subjective symptoms and exposure to organic compounds and asphalt fumes were recorded for 254 workers using warm asphalt for road repair and construction, and for a comparison group of 247 maintenance workers who did not work with asphalt. Mean exposure to asphalt fume was 0.358 mg/m3 (carbon disulfide-soluble fraction). No correlation between symptoms and total amount of volatile compounds was found; however, a significant positive correlation was demonstrated with both increasing concentration of asphalt fumes and increasing asphalt temperature. Abnormal fatigue, reduced appetite, laryngeal/ pharyngeal irritation and cough, and eye irritation were found more often in asphalt workers than in the reference group without asphalt exposure. No differences were found for headache, dizziness, nausea, abdominal pain, disturbed sleep, skin reactions, or a smell of sweetness. The authors conclude that asphalt temperature should be kept below 150 degrees C (302 degrees F), fume concentration below 0.4 mg/m3, and the use of harder asphalt types which also require higher temperatures should be avoided.

As this study is very recent it has not yet been subjected to extensive review and comment. But on its face, an argument could be made that an exposure limit of lower than 0.5 mg/m³ may be necessary to prevent acute health effects, OSHA requests comments on all aspects of the study and the appropriate regulatory response.

A few older reports of respiratory effects of asphalt fumes exist in the literature, although information on exposure levels and the possibility of concomitant exposure with coal tar pitch volatiles is sketchy. Zeglio (1950, as cited in NIOSH, Criteria for a Recommended

Standard * * * Occupational Exposure to Asphalt Fumes, 1977) published observations on 22 workers who insulated electrical cables and telegraph and telephone lines. The workers were exposed to fumes from tanks containing bitumen heated to 120 degrees (presumed to be Celsius). Although the concentration of the fumes was not measured, Zeglio stated that the atmosphere had an acrid odor that was irritating to the nose and throat and that stimulated coughing.

Workers exposed in the plant complained of coughing with expectoration, a burning sensation in the throat and chest, and frequent hoarseness. Headache and nasal mucous discharge were also frequently mentioned by the workers. Physical examination of these 22 workers revealed 10 cases of rhinitis, 13 cases of otopharyngitis, 4 cases of laryngitis, and 19 cases of bronchitis. Roentgenographic

examination revealed an increased vascularization in the larger bronchial areas, particularly evident in the mediobasal zones in all the workers with bronchitis.

Baylor and Weaver (1968) conducted a health survey of asphalt workers from 7 asphalt companies (462 workers) and a control group from 25 oil refineries (379 workers). Physical examinations emphasized the skin and respiratory tract and included chest roentgenograms. Prevalence of respiratory disease other than cancer were reported in 31 of 360 asphalt workers (8.6%) and in 24 of 379 controls (6.3%). Comparison of these rates with National Center for Health Statistics data yields relative risks which are not significantly different. Baylor and Weaver concluded that "* * * petroleum asphalt cannot

rationally be considered a hazardous substance." They did, however, point out that individual predisposition might cause some workers to be subject to health problems with contact with asphalt.

There are a number of studies which consider the issue of the carcinogenicity of asphalt in animals and which consider the prevalence of cancer or the cancer mortality among road paving workers. The following discusses those studies.

Carcinogenicity Data: Animal Studies. The following discusses the toxicological literature, both negative and positive studies, which consider the carcinogenic potential of asphalt fume in animals as evidenced by its ability to

induce tumors in mice in skin painting assays. These studies include the following: Hueper and Payne (1960); Simmers (1965, 1966); Wallcove et al, (1972); Bingham et al (1980); Thayer et al, (1981); Emmett et al. (1981) Malaiyandi et al. (1982); IARC (1985); Belinky et al. (1986); Niemeier et al (1989); and Sivak et al, (1989).

Several studies have reported findings on the carcinogenicity of asphalt by skin painting. A number of studies have sought to correlate the ability of a complex mixture to produce skin cancer in rodents with its ability to initiate lung tumors in humans. For example, Nesnow (1989) found very high correlation between the human lung cancer risk estimates and mouse skin tumor initiation activity of three known carcinogens: coke oven emission. roofing tar emission, and cigarette

smoke condensate.

In a preliminary study sponsored by NIOSH, Thayer et al (1981) reported positive tumorigenic activity when condensate from two different types of roofing asphalt volatile and condensate from two types of coal tar pitch fumes generated at both 232 °C and 316 °C were tested for tumorigenicity. In this study, groups of CD-1 and C3H/HeI mice were treated with one of the four types of asphalt condensates or one of the four types of coal tar pitch condensates. Results indicated that both mouse strains developed skin tumors (papillomas and carcinomas) with the CD-1 mouse being less sensitive to the tumorigenic activity of asphalt fumes than the C3H/HeJ strain. When comparing the tumorigenic response to fumes generated at the two temperatures, the asphalt volatile generated at the higher temperature produced a greater tumorigenic response. Although Thayer et al. (1981) reported a statistically significant increase in the incidence of skin tumors, it is difficult to estimate quantitatively the cancer risk from these data because of the lower reliability of the estimate of q1 (the slope of the dose-response curve) determined from data providing one dose level and a 100% tumorigenic response.

In a paper more fully describing the results of the NIOSH-sponsored study. Niemeier et al. (1988) noted that the carcinogenicity of the asphalt volatile observed in the mouse skin painting experiments previously mentioned in Thayer et al. (1981), could not be entirely accounted for by the concentration of known carcinogens, such as polycyclic aromatic hydrocarbons (PAH) or benzo(a)pyrene (BaP), which is the case for CTPV. Approximately ten-fold more asphalt

fume was required to obtain the same biological effect as CTPV. The amounts of total PAH or benzo(a)pyrene (BaP) found in asphalt fume are 30- to 40-fold less than those amounts found to be effective in eliciting the same response with condensed coal tar pitch fumes. This observation led Niemeier et al. (1988) to hypothesize that the asphalt preparation contained other components which might augment the activity of the very low concentrations of measured PAH found in the asphalt study.

In an attempt to further characterize the components of the asphalt fumes responsible for the carcinogenic activity. Sivak et al. (1989) heated roofing asphalt to 316° C. The fumes generated were fractionated by preparative high performance liquid chromatography (HPLC) and analyzed by gas chromatography/mass spectroscopy (GC/MS). The five fractions collected (labeled A through E) were used in skin application bioassay in male C3H/HeI and Sencar mice (30 animals per test group). Fractions were applied in proportion to their amount in neat asphalt fume.

Fraction C which contained alkylated phenylethanones and alkylated dihydrofuranones had the greatest tumor incidence. Fraction C produced tumors in 17 of 30 C3H mice while fraction B which contained olefins, alkylated aryl thiophenes and alkylated phenanthrenes produced tumors in 10 of 30 C3H mice. The other fractions exhibited no tumorigenic activity. Neither synergism, co-carcinogenicity, nor tumor-promoting activities was observed among the fractions at the concentrations tested.

In a 1988 submission to the Air Contaminants rulemaking docket H020, Exxon reviewed the literature and concluded: "To date, skin painting studies in mice have proven to be the most reliable predictors of the potential carcinogenicity of petroleum-derived materials since these tests reflect the integrated biological response to the presence of tumor initiators, promoters and co-carcinogens" (Exhibit 3-681).

The position of the Asphalt Institute, as stated in their "Report to OSHA and NIOSH, Status of Asphalt Industry Steering Committee Research Program On the Health Effects of Asphalt Fumes and Recommendation for a Worker Health Standard" (1990) is as follows: "The bioassay studies do confirm that some asphalts contain small amounts of carcinogenic species which, if volatilized or otherwise made bioavailable to test animals, may cause skin cancers. But the bioassays do not identify the active species. Nor do they

demonstrate that, under conditions of real world use of all, most, or even any asphalt products, those known constituents are present in fumes in sufficient quantities to yield tumorigenicity in a skin-painting bioassay".

Short-term Tests

The fractions generated in the NIOSH study were used in a modified Ames test of mutagenicity (in which the ability of a test substance to induce revertant in a gene of the TA98 strain of Salmonella typhymurium is determined). This measure of mutagenicity correlated well with the observed mouse skin carcinogenicity (r = 0.94). (Asphalt Institute submission.)

In a recent study, NIOSH reported that fractionated asphalt fume condensate inhibited inter-cellular communication. Most inhibitors of intracellular communication have been observed to have tumor promoting activity. It is hypothesized that the promoting agent serves to isolate an initiated cell from the growth-regulating signals (communications) of surrounding cells leading to the development of

tumors.

In this study NIOSH researchers tested the same fume fractions used in the skin painting study (Sivak) in a metabolic cooperation assay. When wild type Chinese hamster lung fibroblasts are grown in the presence of 6-thioguanine (6-TG), they are killed by its phosphorylated metabolite. Resistant cells do not produce the toxic metabolite and therefore survive exposure to 6-TG. However, in a mixed cell culture containing both sensitive and resistant cell type, there is transfer of the 6-TG metabolite via gap functions from the sensitive to the resistant cells and both types are killed. In the V79 metabolic cooperation assay, co-cultivated 6-TG sensitive and 6-TG resistant cells were exposed to condensate of asphalt fume fractions prior to the addition of 6-TG to the medium. If the test substance inhibited intracellular communication, only those resistant cells which did not receive the toxic 6-TG metabolite from the sensitive cells via gap junctions would survive. The parent mixture of asphalt fume condensate fractions and all of the fractions, except fraction A, inhibited intercellular communication in a concentration dependent fashion (dose-response). Fraction A inhibited metabolic cooperation only at the maximum concentration tested. Fractions D and E, which contained alkylated ketones, alkylated napthols and phenols, were most potent fractions in this assay. The authors hypothesized that "If the similarity between cigarette

smoke and asphalt fume condensates goes beyond inhibition of metabolic cooperation in V79 cells, the carcinogenicity of the asphalt fume condensate may be due in part to the presence of tumor promoters acting through inhibition of intracellular communication."

In a study by Monarca et al. (1987). extracts of bitumen fume demonstrated no mutagenic activity in the Ames test, although the benzo(a)pyrene [B(a)P] concentration predicted that the samples would be positive. This observation led these workers to hypothesize that there was inhibition of mutagenicity due to other sample components. This research group further reported results of biological monitoring of the workers exposed to the asphalt fumes analyzed in their earlier work (Pasquini et al., 1989). The worker exposures were between 0.6 and 0.8 mg/ m3 (total particulate) and were approximately 0.2 mg/m³ measured as benzene soluble fraction. Urine samples from asphalt fume-exposed and nonexposed workers were collected and tested for mutagenicity in the Ames

Microsomal enzyme activation was required for all observed mutagenic activity and was detected only with the TA 98 bacterial strain. Neither of the two additional potential indicators measured, thioether and D-glucaric acid, was significantly different in the exposed and non-exposed groups.

Nine of 11 (82%) non-smokers exposed to asphalt fume had mutagenic urine, while 5 of 18 (28%) of asphalt nonexposed, non-smokers were positive. The urine of all smokers, whether or not exposed to asphalt fume, was positive.

These researchers noted an apparent inconsistency in that environmental samples of asphalt fume were non-mutagenic in their assay, while many of those exposed to asphalt produced mutagenic urine. They offered several explanations: Escape of active components from the fume samples, difficulties inherent to Ames testing of complex mixtures, and, as mentioned earlier, the potential for inhibition of mutagenic activity by other components. They further stated:

* * urinary mutagenicity is considered more meaningful for evaluating human exposure to unknown complex mixtures than ambient monitoring, because it is a nonspecific indicator and can estimate the uptake of the mutagens in the body.

In other words, some metabolism that takes place in the body and converts the exposure to a mutagen is not duplicated in bacterial systems used for the Ames test. Therefore, a mutagenic effect will not be observed in the latter test system, particularly if the toxic chemical requires a multi-step metabolic process for it to become an active mutagen.

Several classes of carcinogens, including polycyclic aromatic hydrocarbons (PAH), are hypothesized to mediate their activity through their metabolic activation to reactive species that subsequently covalently bind to DNA of the cells of the target organ. Shocket et al. (1988a) studied the covalent binding of aromatic compounds to DNA in mouse skin following topical application of coal-tar, creosote or bitumen. The level of adducts (covalently linked species) observed in mouse skin 24 hours after treatment are as follows:

Agent	Dose/mouse (skin)	fmol adduct/µg DNA		
Coal tar	30 mg	0.38		
Coal tar	6 mg	0.14		
Creosote	25 µl	0.40		
Crecsote	5 µl	0.19		
Bitumen	15 mg	0.09		
Bitumen	3 mg	0.00		

Adducts were also detected in lung DNA of treated animals. As with coaltar and creosote, higher levels of accumulation of DNA adducts were observed in skin than in lung following multiple applications.

Schocket et al. (1988b) also looked at the formation of DNA-adducts in human fetal and adult skin cell cultures following treatment with coal-tar, creosote, and bitumen (as a paint formulation containing tetrahydrofuran). These results are as follows:

	fmol adduct/µg DNA				
Treatment	Human adult skin	Human fetal skin			
Control	0.097	0.063			
Coal tar (30 µg)	0.354	0.355			
Creosote (25 µl)	0.313	0.197			
Bitumen (3 µg)	0.000	0.156			
Bitumen (15 µg)	0.216	0.185			

All fetal adduct levels, including those of the bitumen treated, contained statistically significant amounts of adducts. The adult cell cultures treated with 3 µg of bitumen paint solutions failed to produce any adducts. This leads to the point presented by the authors of the possible implications of the ability of fetal tissue to activate the carcinogenic activity of PAHs in utero. These data indicate that bitumen is a less potent inducer of DNA adducts in mouse skin cells, (the site of induction in the in vivo skin painting studies) than it

is in the human skin cells, relative to coal tar and creosote. Another point that Schocket et al. (1988b) mentions is that bitumens have low levels of activity when compared to the coal-tar and creosote, but that there appears to be potential to produce malignant tumors. The authors concluded that bitumen was similar to coal-tar and creosote in forming DNA adducts in the target cells and recommended that "it would seem prudent to regard preparations of bitumen as representing a hazard to man comparable to that of the other two agents" (Schocket et al. 1988b).

The ACGIH TLV for asphalt fume is a TWA of 5 mg/m³ measured as total particulate to reduce the possible risk of carcinogenicity (ACGIH, 1986). However, ACGIH did not specifically designate asphalt fumes a carcinogen. In 1977, NIOSH recommended a 15-minute ceiling value of 5 mg/m³ measured as total particulate based upon the prevention of irritation to the eyes and respiratory tract of workers, and to minimize the possibility of a carcinogenic response from occupational exposure to asphalt fumes (NIOSH, 1977).

In a 1987 publication, IARC concluded that there is sufficient evidence for the carcinogenicity of extracts of steamrefined bitumens and air-refined bitumens in experimental animals; that there is limited evidence for the carcinogenicity of undiluted steamrefined bitumens and for crackingresidue bitumens in experimental animals; that there is inadequate evidence for the carcinogenicity of undiluted air-refined bitumens in experimental animals; and that there is inadequate evidence the bitumens alone are carcinogenic to humans. (IARC 1987) IARC's assessment of asphalt, however, was made prior to the publication of the above mentioned epidemiologic and DNA-adduct studies.

In its Report to OSHA and NIOSH (1990), the AI states: "Quite apart from the unresolved questions about the representativeness of the fume condensates tested by NIOSH, asphalt fumes have been shown to be tumorigenic only in skin-painting studies. Inhalation bioassays have not shown similar effects. By their very nature, skin-painting studies do not generate the dose-response data needed to estimate carcinogenic potency. And still further biological uncertainties are introduced by extrapolating the results of dermal exposures in mice to inhalation exposures in workers". The AI concludes: "The data support a PEL of 5 mg/m3 for asphalt fumes to protect workers against eye and respiratory

tract irritation, but do not support a finding of significant cancer risk".

Epidemiologic Studies

In a recent epidemiologic study of asphalt exposed workers, Hansen (1989) compared the mortality experience between a cohort of 679 mastic asphalt workers with that of all Danish men. These workers' jobs require them to fill buckets with asphalt (at approximately 250 °C), carry the bucket to the area of application where they tip out the asphalt and level it by drawing out the mixture with long wooden trowels. Much of this work is done by the worker while kneeling. The process is used both in flooring and paving operations with the flooring operations having the higher exposure levels.

The 679 male mastic asphalt workers were identified from several sources as having performed mastic asphalt work between 1959 and 1980. Subjects were followed through January 1985. Information on death and emigration was obtained through the Danish National Register. By the end of followup, 149 had died, 6 emigrated resulting in a total of 6,692 person-years of followup. Incident cancer cases were ascertained through the Danish Cancer Registry. Data on individual exposure history was generally not available. Age grouping was taken as proxy for time from first exposure, allowing an

estimation of latency.

The SMR for all malignant neoplasms was 195 (CI, 153–244). Other cancer sites having significantly elevated mortality rates are as follows:

Site	SMR	95% confidence interval
Mouth	1,111	(135-4,014)
Esophagus	698	(144-2,039)
Rectum	318	(128-656)
Lung	344	(227-501)

Two samples taken to measure exposure levels to asphalt fume during road paving, in which approximately 2/3 of the cohort was engaged, were 4.3 and 3.4 mg/m3 with a mean of 4 mg/m3. Thirty five samples taken during flooring operations, in which the remaining 1/3 of the cohort worked, had an average exposure of 20 mg/m3. These estimates of exposure are based on 1976 measurements by the Danish National Institute of Health, and the author of this study has informed OSHA that it is likely an overestimate of exposure since the amount of mastic applied per worker increased during the study period, prior to the 1976 sampling. Dr. Hansen further informed OSHA that the workers

receive approximately 90% compensation during the period of the year in which they cannot perform mastic asphalt work. After adjustment for the seasonal nature of the work, Hansen estimated that the average exposure of mastic workers in the cohort was equivalent to a continuous exposure of 5 mg/m³, the current Danish PEL.

Because coal tar pitch was added to the mastic asphalt mixture during World War II due to shortages of asphalt, it was necessary to determine the number of workers who were potentially exposed to both asphalt fumes and coaltar. In order to do this, the cohort was further divided into three subcohorts. The three subcohorts divided the workers according to the time of birth as follows: Group I (N=194), born 1893-1919; Group II (N=129), born 1920-1929; and, Group III (N=356), born 1930-1960. Group I was the most likely to have exposure to coal-tar during World War II; Group II may have had some coal-tar exposure in World War II, and Group III could not have had wartime exposure. The lung cancer SMRs for all three groups (302, 392, and 857 respectively) were significantly elevated, further supporting the role of asphalt in this tumor excess. The results also suggested that the increased lung cancer risk manifested itself earlier (at younger ages) in the subsequent birth cohorts, but numbers of cancers in this youngest group were too small to reach statistical significance. Hansen also adjusted the respiratory and digestive cancer SMRs for estimated confounding effects of urbanization and smoking habit. This adjustment resulted in somewhat lower SMRs of 214 and 206 for respiratory and digestive cancers respectively, but still demonstrated statistically significant excess risk.

In this incidence study, urinary system cancer, which includes bladder cancer. known to be smoking-related, showed no statistically significant increase (SMR=133). In a subsequent mortality study of this cohort, Hansen (1990) reported that an SMR of 100 for cardiovascular disease deaths-a cause of death also known to be associated with smoking. Thus, two major causes of death related to cigarette smoking were not elevated among the cohort members. These observations suggest that cigarette smoking is unlikely to have accounted for the excess lung cancer observed in the study.

In a subsequent mortality study of this cohort, Hansen (1990) reported that a 1976 survey of mastic workers (110 members of the study cohort) indicated that 22% were non-smokers, 36%

consumed less than 14 grams of tobacco per day, and 43% consumed 15 or more grams per day, while a 1982 Danish population-based survey gave these percentages as 39, 24 and 30% respectively. She used the lung cancer death rates among non-smokers. medium smokers, and heavy smokers from the Doll and Peto study (1976) to estimate that these differences in smoking would bring about an 18% excess of lung cancer deaths and 21% excess of the bronchitis deaths in her cohort of workers. This adjustment of the SMR for lung cancer lowered the estimate from 290 to 246.

Similarly, because most of the cohort was from urban areas of Denmark and the comparison population contained both urban and rural groups, adjustment for urbanization was also undertaken. The correction which was based on Danish census data, lowered the estimate of the SMR for lung cancer from 290 to 264. Independent adjustment for both, a procedures which overadjusts because smoking and urbanization are related, still resulted in a statistically significant SMR of 224.

Hansen (1989a) also undertook a separate epidemiologic study comparing mortality between 1,320 workers employed in the Danish asphalt industry with that of 43,024 workers from service trades, agriculture, forestry and specific light industries. She found a significantly increased mortality for all malignant neoplasms among asphalt workers aged 45 or more when 5 years of latency was taken into account (SMR 159, 95% confidence interval, 106-228) compared with other unskilled workers. There were increases for respiratory, bladder and digestive cancers, but these increases were not statistically significant. No attempt was made to assess exposure levels—the only criteria for a subject to be in either exposure category were his occupation and being employed on the date of the census, which is likely to have diluted any differences. For instance, the comparison group might have included asphalt-exposed workers who were not employed in asphalt work on that date. Similarly, the "exposed" group might have included workers with low cumulative asphalt exposures.

Epidemiologic studies by Hammond et al. (1976) Menck and Henderson (1976), and Milham (1982) reported increased standardized mortality ratios or proportionate mortality ratios for lung cancer among roofers and slaters. It is difficult to establish a clear association between asphalt exposure and lung cancer in these studies because most workers had combined exposures to

asphalt and coal tar, and smoking histories of the workers were not known.

A study by Baylor and Weaver (1968) reported no significant differences in a cross-sectional survey on the health of 462 asphalt workers compared with the health of 379 refinery workers. These workers had asphalt exposures for at least 5 years and were then given a physical examination, which included a medical and occupational history. No significant differences were noted between the 2 groups of workers regarding: respiratory diseases, skin cancer, non-carcinogenic skin disease, hypertension, ulcer, heart disease, or other cancers. This is not an appropriate study for demonstrating whether or not there is an excess risk of cancer for a number of reasons. Without mortality data and longer follow-up, few conclusions regarding the risk of asphalt exposure can be drawn from these studies. Since refinery workers are also exposed to PAHs, etc., they are therefore not a true control group for asphalt fume exposures.

Based on preliminary reports of excess leukemia among highway maintenance workers in a small Minnesota community, Bender et al (1989) assembled a cohort of Minnesota highway maintenance workers and determined their cause-specific mortality and compared this rate with that of the entire Minnesota population. This study had a large number of subjects (4,849) and deaths (1,530), and lengthy and nearly complete follow-up (99.6%). The authors did not, however, present any exposure information. The results indicated a statistically significant SMR of 425 for leukemia mortality among those with 30 to 39 years of work and, as mentioned earlier, a significant SMR of 292 for urologic cancer among those having 40 to 49 years of latency. Lung cancer SMRs and other cancer SMRs were not significantly elevated.

In its "Briefing Paper On the Regulation of Asphalt Fumes" the Asphalt Institute described this study by Bender as "(T)he best study of U.S. asphalt workers," and stated that it found no increased mortality at any relevant cancer site. In a letter to OSHA staff Dr. Parker, a secondary author of the Minnesota Highway Maintenance Worker Study, stated that this study "does not support a contention, either pro or con, with regard to the potential carcinogenicity of asphalts. Although the primary workers we evaluated performed highway maintenance work, these workers were not primarily involved in road construction" (where

they would be most likely to be exposed to asphalt fumes).

Parker et al (1989) reported the results of a study on the same cohort in which non-cancer causes of death were analyzed. The SMR for renal failure among long-term rural workers was significantly elevated (SMR=676) as was the SMR for transportation-related injuries (SMR=280). The lack of information on the exposures of this cohort render it of little value in determining the level of risk from exposure to asphalt and does not allow the determination of risk levels among more highly exposed subgroups.

Quantitative Risk Assessment

The best available human data for quantifying the lung cancer risk associated with paving workers is found in the Hansen study of Danish mastic asphalt workers (Hansen 1989b). This study has the best exposure data along with estimates of relative risk of cancer in humans to evaluate a dose-response relationship. If some cohorts of workers in this study did not have substantial exposure to coal tar pitch volatiles, (CTPV) a known carcinogen, then this study provides quantitative evidence of cancer risk from asphalt. The issue of CTPV exposure is controversial and discussed below.

Hansen derived the mean exposure level of asphalt fume in her study cohort, 5.4 mg/m³, as follows: two thirds of the cohort was engaged in road paving operations, having a mean exposure level of 4 mg/m³; one third was involved in flooring operations, having a mean exposure to asphalt fume of 20 mg/m³; and, that exposure occurred only during seven months of the year. This leads to:

 $\frac{[(^{1}/_{3}\times20 \text{ mg/m}^{3})+(^{2}/_{3}\times4 \text{ mg/m}^{3})]\times^{7}}{_{12}=5.4 \text{ mg/m}^{3}}.$

OSHA assumed that exposure began at 22.5 years of age and continued at a constant level for 45 years. These assumptions are reasonable because Hansen stated in the report of this study that new mastic workers are always young, typically in their early twenties, and that the turnover in this job is moderate. Dose was estimated in units of milligrams per cubic meter-years (mg/m³-yr) and the expected cancer incidence was calculated from age-, period-, and site-specific incidence rates for Danish men during the period 1958–1982.

A relative risk model was used to quantify the risk from occupational exposure to asphalt fume. The relative risk model is based on the assumption that the increase in the relative risk of lung cancer death due to asphalt fume exposure is the product of an individual's background risk at time t, $h_o(t)$, and the risk attributable to asphalt fume exposure, $h_o(t)$. The risk attributed to asphalt fume exposure is given by $h_o(t) = \beta X$.

where X represents cumulative dose up to time t. An individual's total risk of lung cancer death at time t, h(t), is given by

 $h(t) = h_o(t) + (h_o(t)h_e(t))$ = $h_o(t) + (h_o(t)\beta X)$.

This model can also be written as a linear model where

$$\frac{h(t)}{h_o(t)} = 1 + \beta X.$$

Here, 1 is the intercept (i.e. the relative risk assuming no exposure), and β is the slope of the dose-response line representing the change in relative risk per unit dose.

If we consider each individual to be an independent Bernoulli trial and sum over all individuals in the jth exposure group, we obtain the expected number of lung cancer deaths for the period of observation, $E(O_j)$, which is given by $E(O_j) = E_j + (E_j \beta X_j)$,

where E_i is the expected number of cases assuming no asphalt exposure, (i.e. background), and X_i is the median dose for exposure group j. Assuming that the observed number of deaths is distributed as a Poisson random variable with expectation given above, we obtain the likelihood of observed results

LIK=
$$\prod_{j=1}$$
 [exp-(E_j + (E_j βX_j)]
[E_j + (E_j βX_j)]/O_j

The maximum likelihood estimate of the unknown parameter β is obtained by maximizing the log likelihood with respect to β . The variance of β is given by the inverse of the observed information. We solve for the parameter β using a Newton-Raphson algorithm. Estimates of β and its variance derived from the Hansen data using the relative risk model are given in Table 1.

The relative risk model rests on the assumption that the ratio of the risk of

lung cancer death for asphalt-exposed individuals to the risk of lung cancer death for individuals with no asphalt exposure depends only on dose and is constant across age groups. In other words, for any given cumulative dose, the risk of death for a twenty-five year old exposed individual relative to a non-exposed twenty-five year old individual is the same as the risk of death for a fifty year old exposed individual relative to a non-exposed individual of the same age.

OSHA recognizes the importance of this assumption in estimating true occupational risk. Thus, OSHA specifically requests comments concerning the significance of assumptions and their applicability for estimating risks from exposure to inhaled asphalt fume.

After fitting the model to the data, it is reasonable to ask whether or not the fit is good. The standard approach for measuring goodness-of-fit is to perform a Chi-Square test, in this case calculating the deviation of the number of lung cancers predicted for each exposure group from the number of lung cancers observed in each group. The number of lung cancers predicted for the jth exposure group, O_j, is given by

$$O_i = E_i + (E_i \beta X_i),$$

where E_j is the expected number of lung cancers for the jth exposure group, X_j is the median continuous dose expressed in mg/m^3 -years for the jth exposure group , and β is the estimated parameter for the relative risk model (given in Table 1). The numbers of lung cancers predicted by the model for each exposure group are presented in Table 3. The goodness-of-fit Chi-Square is 14,0 on 18 degrees of freedom, therefore, OSHA concludes that the model provides a reasonable fit to the observed data.

Gail describes an approach for estimating the excess risk of cancer death due to constant exposure to environmental carcinogens in the presence of competing risks (From Cadmium docket #, Ex. 8–651). This method is easily adapted to estimate the excess risk of lung cancer death due to occupational exposure to asphalt.

Occupational dose was first converted to continuous dose on the assumption that exposure occurs 8 hours per day, 5 days per week and 48 weeks per year. The lung cancer death rates, which were given for five-year age intervals, were assumed to be constant throughout each interval.

Let d_i=the cumulative dose received at the midpoint of the ith age interval. Thus, for example, if an individual is exposed at a constant level X from age 20 on, then at age 24, d₂₄ would equal 4.5X. From age 65 on, cumulative exposure would be 45X. Let q_x(i)=the probability of death from all causes at age i, and let q_L(i)=the probability of lung cancer death at age i.

Using the relative risk model and the MLE of β derived from this model above, the lifetime excess risk of lung cancer due to 45 years of occupational exposure to asphalt fume is given by

$$7 \sum_{i=20}^{j} \beta d_{i} q_{L}(i) \exp \left[-\frac{1}{2} \sum_{j=20}^{j} \beta d_{j} q_{L}(j) + q_{x}(j)\right].$$

Table 3 presents estimates of excess deaths derived from the Hansen data using the method described here. In addition, 95% upper confidence limits and 5% lower confidence limits were constructed for each of the MLEs. This was done by replacing β by $\beta\pm1.645$ SE(β) and using the formulas above.

Using data for the entire cohort, and assuming no substantial contribution to the lung cancer risk from CTPV, exposure to 0.2 mg/m3 of asphalt fume for the occupational lifetime is associated with an estimated excess cancer death rate of one per 1,000 workers. This rate is based on the maximum likelihood estimate. The 95percent upper bound estimate or risk corresponding to this dose is about one and a half excess lung cancer deaths per 1,000 workers. By comparison, the maximum likelihood estimate of risk for lifetime exposure to 0.5 mg/m3 or 1.0 mg/m3 are 2.5 and 5 excess deaths per 1,000 workers respectively. The estimate at a lifetime exposure of 5 mg/m3 is 25 deaths per 1,000 workers.

A similar assessment of risk was performed using data representing only that portion of the cohort which was born between 1930 and 1960. Dr. Hansen believes that these workers did not have any exposure to CTPV, and the Asphalt Institute believes they had some

exposure. The resulting risk estimates were higher than those of the entire cohort of mastic workers. However, the numbers of deaths in this cohort were quite small and accordingly, the risk estimates have wide confidence intervals. Therefore the combined cohort may be more useful for estimates of risk.

In extensive submissions to OSHA, the Asphalt Institute (AI) presented its research program and the results of research to date. Included was a report by A. Kriech and J. Kurek in which they described the chemical analyses of core samples of Copenhagen roadways, purported to have been paved with mastic asphalt by the cohort of workers studied by Dr. Hansen. AI requested that the Danish Road Laboratory locate pavements and take core samples from roadways applied approximately every five years. In this report, core samples were identified by year of application and street name. Al concluded from the quantification of polynuclear aromatic hydrocarbons present in the core samples, that "* * * this study has produced persuasive evidence that the workers studied by Dr. Hansen were exposed to significant concentrations of coal tar fumes * * **

Dr. Hansen, who performed the study, has informed OSHA that in interviews with mastic asphalt workers and other plant personnel, she was told that following World War II, coal tar use was avoided. For example, an engineer who formulated asphalt at one of the studied facilities related to Dr. Hansen that coal tar was not used at his company in either the lower (Pulver) layer or the mastic layer after 1949. He further stated that migration of coal tar from lower layer(s) into mastic asphalt would make the mastic asphalt less suitable by altering its properties

making it soft when warm and brittle when cold.

Further, Dr. Hansen has informed OSHA that the core sampling and analyses will be repeated under controlled circumstances by an independent institution. OSHA anticipates that these data will become available to the Agency during this rulemaking. The evidence presented by Dr. Hansen is not certain because some of it relies heavily on human recollection.

The evidence for concomitant exposure presented by AI is also not certain. The accuracy of the records is undetermined. Information regarding the nature of any repairs of the sampled roadways subsequent to application of the mastic asphalt, which might have included coal tar, was not included in the report. The potential migration of the measured chemical components of the core samples was not discussed. In addition, it is unclear to what degree the PAH measurements made by AI discriminate between asphalt and coal tar. Moreover, it is not clear that the AI core samples were taken from the roads which were paved by the studies workers, who paved specifically with mastic asphalt.

If AI's suppositions are accurate and part of the increased risk of lung cancer in the Danish mastic asphalt worker cohort was due to concomitant exposure to coal tar pitch volatile (CTPV), the risk estimates due to asphalt exposure would be less certain. If Dr. Hansen's views are the better supported, then more confidence is given to the risk estimates.

estimates.

OSHA is proposing a PEL for asphalt fumes of 5 mg/m³ total particulate as an 8-hr. TWA for general industry, construction, maritime and agriculture. That was the level which OSHA

proposed for general industry in 1988, and is the ACGIH recommendation.

NIOSH's original recommendation was 5 mg/m³ as a 15-min. STEL. One of OSHA's procedures for the Air Contaminants rulemaking was to make use of ACGIH and NIOSH recommendations for its proposals, but base its final decisions, of course, on all evidence, comments, and views.

Subsequent to OSHA's original proposal and the recommendations of NIOSH and ACGIH, new studies have become available. However, at this time only one commenter, the Asphalt Institute, has provided comment on these new studies (Docket office, Docket #H-020A). The Norseth study is so recent that OSHA has not received a single comment on it as yet.

In light of the number of significant new studies and the varying conclusions that can be drawn from them, arguments can be made to support PELs of 5 mg/m³, 1 mg/m³, 0.5 mg/m³ and 0.2 mg/m³. The selection of a PEL depends on one's conclusions as to the level at which irritation and other respiratory effects occur, the relevance and persuasiveness of the carcinogenicity evidence, and the relevance of the risk assessment. The Regulatory Impact Analysis presents exposure data and other information as to feasibility of all of these levels.

OSHA requests comments on all the evidence, studies and analyses, its proposal of 5 mg/m³ total particulate as an 8-hr. TWA, the other exposure limits mentioned, the appropriate method of measurement and all other relevant issues. Comment is also requested on whether different fractions of asphalt may have different health effects, and whether it may be appropriate to take this into consideration in final regulatory decisions.

BISMUTH TELLURIDE (Se-DOPED) CAS: 1304-82-1; Chemical Formula: Bi₂Te₃

H.S. No. 1034

OSHA has no limit for doped bismuth telluride in the construction, maritime, or agriculture industry. The ACGIH has a TLV*-TWA of 5 mg/m³ for bismuth telluride that has been doped with selenium sulfide. NIOSH has no REL for this substance. The Agency is proposing a PEL of 5 mg/m³ as an 8-hour TWA in construction, maritime, and agricultural operations. NIOSH (Ex. 8-47, Table N1) concurred with this limit when the Agency recently established it in general industry.

Bismuth telluride takes the form of gray, hexagonal platelets; it is also available as ingots or single crystals. Bismuth telluride is used for semiconductors and in thermoelectric cooling and power generation applications (ACGIH 1986, p. 59).

Wagner, Madden, Zimber, and Stokinger (1974) conducted a one-year study in which rabbits, dogs, and rats were exposed for 6 hours/day, 5 days/ week to doped bismuth telluride dust (containing 80.04 mol % Bi₂Te₃ and 0.20 mol % SnTe, plus a small stoichiometric excess of Te) of 1.04 um particle diameter at a mean concentration of 15 mg/m³. Small, granulomatous lesions without fibrosis appeared in the lungs of dogs at 6 months. In dogs that were sacrificed four months after an 8-month exposure, the lesions had regressed, and the affected lymph nodes were without cellular reaction. Rabbits exhibited similar histologic effects, but with decreased numbers of pulmonary macrophages, no fibrous tissue proliferation, and no cellular or fibrous tissue reaction around the dust deposits in the lymph nodes. The rats showed fewer granulomas but some areas of epithelialization of the alveolar walls. As was true for the other species, the rats showed neither fibrosis nor cellular reaction in the lymph nodes, despite accumulation of the intermetallic dust (Wagner, Madden, Zimber, and Stokinger 1974).

In humans, exposure to bismuth telluride (whether doped or not is not specified) is reported to lead to eye, nose, and throat irritation (Hazardous Substance Fact Sheet 1985). Exposure to the doped telluride is known to cause garlic breath, a sign of exposure both to tellurium and selenium (Clayton and Clayton 1981, p. 1561).

OSHA is proposing an 8-hour PEL of 5 mg/m³ TWA for Se-doped bismuth telluride in the construction, maritime, and agriculture industries to prevent the occurrence of pulmonary lesions in

exposed workers. OSHA preliminarily concludes that this limit will substantially reduce the significant risk of these pulmonary effects, which constitute material impairments of health. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

CARBON BLACK CAS: 1333–86–4; Chemical Formula: C H.S. No. 2027

Currently, OSHA has an 8-hour TWA limit of 3.5 mg/m³ for carbon black in general industry and in the construction and maritime industries. There is no limit in agriculture. The ACGIH TLV*—TWA and NIOSH REL are both 3.5 mg/m³; however, NIOSH also recommends that carbon black containing more than 0.1 percent polyaromatic hydrocarbons be handled as a potential human carcinogen. OSHA is proposing to extend its 3.5 mg/m³ 8-hour TWA PEL to agricultural workplaces; this action will make the PEL for carbon black consistent across all regulated sectors.

Commercial carbon black is a finely divided form of carbon that contains trace amounts of organic and inorganic impurities adsorbed on the surfaces of the particles. Oil furnace black, which typically contains less than 0.1 percent solvent-extractable impurities, is the most widely used of the carbon blacks in the United States.

Data on humans and animals suggest that exposure to carbon black at high levels is associated with declines in pulmonary function and cardiovascular stress. Oleru et al. (1983) reported a significant loss of pulmonary function among a group of 125 Nigerian carbon

black workers exposed to airborne concentrations as high as 34 mg/m3; radiograms taken on members of this population were normal. Another study, reported in an abstract (Crosbie et al. 1979), found significant annual declines in pulmonary function, as well as radiologic changes, in a group of 35 workers exposed to carbon black concentrations below 10 mg/m3. Nau et al. (1962) exposed hamsters, mice, guinea pigs, rabbits, and monkeys to 56.6 mg/m3 furnace black (carbon black) for prolonged periods of time. Electrocardiographic changes were noted in monkeys after 2500 hours of exposure, and marked right atrial and right ventricular strain were noted in these animals after 10,000 hours of exposure. The authors attributed these effects to the excessive accumulation of carbon black dust in the lung.

More recent studies conducted in U.S. carbon black plants, where OSHA's 3.5 mg/m3 PEL is in force, report no association between exposure and excess morbidity. In a cross-sectional study of pulmonary function in 913 U.S. carbon black workers, Robertson et al. (1988) found no significant declines in pulmonary function after correcting the data for age and smoking habits. Robertson and Ingalls (1989) also conducted a case-control study of all male carbon black production workers in the United States. In this study, a case was defined as a member of the study population who had filed a health insurance claim for a physician's diagnosis of malignant neoplasm. circulatory disease, or pulmonary disease. No associations were found in this study between cumulative exposure level of carbon black and diagnoses of these disorders.

OSHA is proposing an 8-hour TWA PEL of 3.5 mg/m³ for agricultural workplaces. The Agency preliminarily concludes that this limit is necessary to protect workers in this sector against the significant risk of pulmonary and cardiovascular disorders that have been associated with exposure to high concentrations of carbon black. OSHA considers these effects material impairments of health and believes that the proposed limit will substantially reduce this risk. Promulgation of this limit will also make OSHA's PEL for this substance consistent across all regulated sectors.

CHLORINE DIOXIDE CAS: 10049-04-4; Chemical Formula: ClO₂ H.S. No. 1080

Currently, OSHA has an 8-hour TWA limit of 0.1 ppm for chlorine dioxide in the construction and maritime

industries. There is no limit in agriculture. The ACGIH has the same time-weighted average TLV*, plus a 15-minute TLV*-STEL of 0.3 ppm. NIOSH has no REL for this substance. The Agency proposes to add a 15-minute STEL of 0.3 ppm to its current limit in construction and maritime and to extend both the 8-hour TWA and 15-minute PELs to agriculture. NIOSH concurred (Ex. 8-47, Table N1) with these limits when OSHA recently established them in general industry.

Chlorine dioxide is a red-yellow gas at ordinary temperatures. It is used as a biocide, to bleach textiles, paper pulp, flour, cellulose, leather, fats and oils, and in beeswax. Chlorine dioxide is also employed in purification, taste and odor control of water, as an oxidizing agent, and in the manufacture of chlorite salts (ACGIH 1986, p. 118; Hawley's 1987, p. 260). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

In addition to respiratory effects, chlorine dioxide can cause eye irritation, gastrointestinal irritation, and reproductive effects in experimental animals. The oral LD50 in rats is 292 mg/ kg. Exposure causes pulmonary effects and skin irritation in rabbits. Instilled into rabbit eyes, 100 mg of chlorine dioxide caused mild irritation (RTECS 1991). Rats exposed to 0.1-ppm concentrations of chlorine dioxide for 5 hours/day for 10 weeks showed no adverse effects from exposures (Dalhamn 1957/Ex.1-307). Chlorine dioxide also has reproductive effects in rats and embryotoxic effects in their offspring (RTECS 1991).

Data on human exposures indicate that marked irritation occurs on inhalation of 5 ppm (no time specified), and that one death occurred after exposure to 19 ppm (Elkins 1959). Repeated exposures in humans have been linked to bronchitis and pronounced emphysema (Petry 1954/ Ex.1-1163). Clinical studies conducted by Gloemme and Lundgren (1957/Ex.1-323) revealed that the majority of workers who had been exposed for five years to average concentrations of chlorine dioxide below 0.1 ppm, in combination with about 1.0 ppm chlorine, experienced eye and respiratory tract irritation and slight bronchitis. Some gastrointestinal irritation was also observed in these workers. Gloemme and Lundgren (1957/ Ex.1-323) attributed all of these effects to elevated short-term exposures involving excursions above the 0.1 ppm level. Ferris, Burgess, and Worcester (1967/Ex.1-316) have shown that

concentrations occasionally ranging as high as 0.25 ppm were associated with respiratory effects in workers concomitantly exposed to chlorine.

OSHA is retaining the 0.1-ppm 8-hour TWA PEL and is proposing to add a 15minute STEL of 0.3 ppm for chlorine dioxide in construction and maritime; the Agency also is proposing to extend both limits to agricultural operations. OSHA preliminarily concludes that both of these limits are necessary to protect workers in these sectors from the significant risk of respiratory, skin, and eye irritation known to occur as a result of exposure to this substance. OSHA considers these adverse effects material impairments of health and believes that promulgation of these limits is necessary both to reduce these significant risks and to make OSHA's PELs for this substance consistent across all regulated sectors.

CHROMIUM (II) COMPOUNDS CAS: 7440–47–3; Chemical Formula: Cr H.S. No. 2083

OSHA has no limit for the chromium II (divalent) compounds in construction, maritime, or agriculture. NIOSH has no REL but concurs (Ex. 8–47, Table N3A) with the limit being proposed. The ACGIH has a TLV*-TWA of 0.5 mg/m³ for the divalent chromium compounds, and OSHA is proposing the same limit for these substances in workplaces in construction, maritime, and agriculture. This action will make OSHA's limit for the chromium II compounds consistent across all industry sectors.

Chromium is a metallic element that can have a valence of 2, 3, or 8; the divalent, or chromium II, compounds include such substances as chromous bromide, chromous carbonate, chromous chloride, chromous fluoride, and chromous sulfate. These compounds are used as reducing agents, catalysts, reagents, and oxygen scavengers, and as components of electroplating solutions [Hawley's 1987, p. 282].

The chromium compounds vary greatly in toxicity, but the chromium II compounds in general are believed to have a relatively low order of toxicity (ACGIH 1986, p. 139). The available toxicological literature often does not distinguish between the various compounds, and information on the divalent form is rare. There are no acute toxicity studies in animals for the divalent forms. These compounds, however, do appear to have sensitization potential when in contact with the skin. Some workers have demonstrated positive patch tests after exposure to divalent chromium

compounds in the workplace (Burrows

OSHA is proposing an 8-hour TWA limit of 0.5 mg/m3 for the chromium II compounds in construction, maritime, and agriculture. This is the PEL currently in effect in general industry, and the Agency believes this limit is necessary both to reduce a significant risk of sensitization among construction, maritime, and agricultural workers and to make the Agency's limit for these substances consistent across all regulated sectors. OSHA considers dermal sensitization a material health impairment and believes that the proposed PEL is necessary to substantially reduce this significant risk. **CHROMIUM III COMPOUNDS** CAS: 7440-47-3; Chemical Formula: Cr H.S. No. 2039A

OSHA has no limit for the chromium III (trivalent) compounds in construction, maritime, or agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. The ACGIH has a TLV*-TWA of 0.5 mg/m³ for the trivalent chromium compounds, and OSHA is proposing the same limit for these substances in construction, maritime, and agriculture. This action will make OSHA's PEL for the chromium III compounds consistent across all industry sectors.

Chromium is a metallic element that can have a valence of 2, 3, or 6; the trivalent, or chromium III, compounds include such substances as chromic oxide, chromic sulfate, chromic chloride, chromic potassium sulfate, chromic carbide, and chromite ore (ACGIH 1986, p. 139; Clayton and Clayton 1981, p. 1591). Chromic compounds are used as textile mordants, paint pigments, and catalysts, in refractory bricks, and in gauge blocks, hot extrusion dyes, and as a spray-coating material (Clayton and Clayton 1981, pp. 1590–1591).

The oral LD50's for various chromic salts range from 600 to 2600 mg/kg (Smyth, Carpenter, Weil, Pozzani, Striegel, and Nycum 1969). Guinea pigs repeatedly exposed to chromic salts developed allergic contact dermatitis (National Research Council Canada 1976). Mice pretreated with a 12 mg/kg dose of chromium III compounds experienced a 250 percent increase in mortality when subsequently challenged with a 120 mg/kg dose of chromium III (Yoshikawa 1970). In-vitro studies show that exposure to chromic compounds reduced the viability of rabbit alveolar macrophages and increased cell lysis (Walters et al. 1975). Rats exposed for one year via their drinking water to 0 to 25 mg/liter chromium III showed no

significant differences from controls in body weight gain, appearance, or blood or tissue pathology (MacKenzie, Byerrum, Decker, Hoppert, and Langham 1958). Rats exposed to chromium oxide pigments in the diet for 2 years showed no increase over controls in tumor rates (Ivankovic and Preussman 1975).

In humans, exposure to the dust of chromite ore has caused "exaggerated" lung markings on chest roentgenograms, and other groups of ore workers have developed pneumoconiotic changes consistent with histologic fibrosis (ACGIH 1986, p. 139; Mancuso and Hueper 1951). One case of asthma caused by exposure to a chromic compound (chromic sulfate) has been reported and confirmed in a plating worker (Novey et al. 1983). Eighteen percent of 85 chrome factory workers exposed to 4.5 to 9.2 mg/m3 Cr III compounds developed chronic bronchitis after 5 years of exposure, and almost 6 percent of these factory workers developed pneumoconiosis after 9 years of exposure (Mikov 1967, in

Based on these effects in humans and animals, OSHA is proposing an 8-hour TWA PEL of 0.5 mg/m3 for the chromic (Cr III) compounds of chromium; this limit would apply in construction, maritime, and agricultural workplaces. OSHA believes the proposed PEL is necessary to reduce the significant risk of chronic respiratory effects in workers in these sectors who are exposed to these compounds. The Agency considers chronic respiratory effects such as pneumoconiosis and chronic bronchitis material impairments of health. Promulgation of this PEL will also make OSHA's limit for the Cr III compounds consistent across all regulated sectors. CHROMIUM, METAL

CAS: 7440-47-3; Chemical Formula: Cr H.S. No. 1093

OSHA currently has an 8-hour TWA PEL of 1 mg/m³ for chromium metal in general industry, construction, and maritime. There is no limit in agriculture. NIOSH has no REL for this substance, and the ACGIH has established an 8-hour TLV®-TWA of 0.5 mg/m³ for chromium. The Agency is proposing a 1 mg/m³ 8-hour TWA limit for chromium in agricultural operations. NIOSH concurs (Ex. 8-47, Table N1) that this limit is appropriate. Promulgation of this limit will make OSHA's PEL for chromium consistent across all regulated sectors.

Chromium is a hard, brittle, semi-gray metal. Chromium is used for corrosion resistance and as an alloying and plating element on metal and plastic substrates. It is also used as a protective coating for automotive and equipment accessories, in nuclear and hightemperature research, and in inorganic pigments (Hawley's 1987, p. 280).

Chromium metal is relatively nontoxic. Some studies in experimental animals have shown that a few animals develop tumors after intravenous injection; however, the relevance of these results for occupational exposure is not clear. In the general industry rulemaking, OSHA found that the preliminary markings reported in the Mancuso and Hueper (1951/Ex.1-215) study did not present a risk of material impairment of health in exposed workers because these markings did not presage any decrement in pulmonary function or interfere with the functional capacity of exposed workers. A study by Princi et al. (1962) reflects the problem of confounding exposures in the case of chromium. In this study, ferrochrome alloy workers were exposed to several toxic contaminants simultaneously, including chromium salts, silica, iron oxide, and chromium metal. OSHA believes it likely that exposure to the other contaminants present, which included a high percentage of silica, accounts for the development of pulmonary disease in these workers. The ACGIH (1986/Ex.1-3, p. 139) stated, after reviewing the Mancuso and Hueper (1951/Ex.1-215) and the Princi et al. (1962, as cited in ACGIH 1986/Ex.1-3, p. 139) studies, that "[e]xposure to chromium metal does not give rise to pulmonary fibrosis or pneumoconiosis." Other authors (Proctor, Hughes, and Fischman 1988) concur in this assessment of the relative lack of toxicity of the metallic form of chromium.

Based on this evidence, OSHA is proposing an 8-hour TWA limit of 1.0 mg/m³ for chromium metal in the agriculture industry. The Agency believes that this limit is adequate to protect workers in agriculture from the significant risk of pulmonary effects potentially associated with exposure to the metallic form of chromium. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

COAL DUST, < 5% QUARTZ COAL DUST, > 5% QUARTZ CAS: None; Chemical Formula: None H.S. Nos. 1096 and 1097

In the construction and maritime industries, OSHA's current limits for coal dust are expressed as a formula limit of 10mg/m³/%SiO₂+2 (8-hour TWA) for coal dust containing a respirable quartz fraction greater than 5 percent and a 2.4-mg/m³8-hour TWA

limit for coal dust containing a respirable quartz fraction of less than 5 percent. There is no limit in agriculture. The ACGIH has a TLV®-TWA of 0.1 mg/m3 for the respirable quartz fraction of coal dust containing more than 5 percent quartz and of 2 mg/m3 for the respirable dust fraction of coal dust containing less than 5 percent quartz. NIOSH has no RELs for this substance. In agriculture, OSHA is proposing an 8hour TWA limit of 0.1 mg/m3 for the respirable quartz fraction of coal dust containing more than 5 percent quartz and an 8-hour TWA limit of 2 mg/m3 for the respirable dust fraction of coal dust containing less than 5 percent quartz. The Agency is also proposing that the current limit for coal dust containing more than 5 percent respirable quartz in construction and maritime be expressed as mg/m3, which reflects the current approach to airborne particulate measurement; this action would establish a PEL of 0.1 mg/m3 for coal dust containing more than 5 percent respirable quartz. OSHA's proposed limit in these two sectors thus does not represent an actual change in the value of the limits for coal dust containing more than 5 percent respirable quartz; instead, it would do away with the Agency's cumbersome formula limit. In all sectors-construction, maritime, and agriculture—OSHA is proposing a PEL for coal dust containing less than 5 percent quartz of 2 mg/m3.

Coal is a dark brown to black solid formed from fossilized plant material. Coal is used as a fuel and in the manufacture of fertilizers, insecticides, disinfectants, synthetic rubber, and in the production of coke, coal gas, water gas, and coal tar compounds (ACGIH, 1986, p. 142.1 [87]).

The literature on occupational exposure to coal dust does not generally distinguish between dusts containing less than 5% respirable quartz and dusts containing a higher percentage of respirable quartz. The discussion below also does not make this distinction.

Animal data on coal dust effects are sparse. Rats inhaling 6600 μ g/m³ coal dust for 86 weeks (6 hours daily) developed lymphomas, and those inhaling 14,900 μ g/m³ on the same regimen developed tumors of the adrenal cortex (AIHAJ 1981).

Exposure to coal dust can cause respiratory effects such as pneumoconiosis, bronchitis, emphysema, and progressive massive fibrosis (PMF) in humans. Coal worker's pneumoconiosis (CWP) often occurs concomitantly with chronic bronchitis and emphysema. The small opacities associated with CWP are most frequently located in the upper lung

zones. CWP is also a precursor to progressive massive fibrosis, which is associated with reduced ventilatory capacity, low arterial oxygen tension, pulmonary hypertension, and premature death (Morgan 1984). A study conducted from 1969 to 1971 showed that, in 9,076 U.S. miners, there was an overall 30 percent prevalence of CWP, with 2.5 percent experiencing progressive massive fibrosis (Morgan 1973). In some workers reporting symptoms of chronic bronchitis, even moderately low exposure to coal mine dust was associated with severe lung function impairment (Hurley and Soutar 1986). A recent study in Welsh and English miners demonstrates that lifetime exposure to coal mine dust is related to increased mortality due to pneumoconiosis, bronchitis, or emphysema (Miller and Jacobsen 1985).

NIOSH (Ex. 8-47, Table N2; Tr. p. 3-86) believes that the limit for quartzbearing coal dust should be reduced to 0.05 mg/m3 as an 8-hour TWA on the basis of the potential carcinogenicity of respirable crystalline silica. OSHA is aware of some recent studies (NIOSH 1986b; Hurley and MacLaren 1987; IARC 1987) on the health effects of exposure to coal dust, and the Agency is monitoring this literature to assess the need for a reevaluation of this limit in the first PEL Update. However, OSHA's primary objective in the present rulemaking is to achieve consistency of limits across all sectors, and the adoption of the proposed coal dust limit in agriculture will achieve that goal. In addition, expressing these limits in terms of mg/m3 rather than the formula will simplify measurement in workplaces in construction and maritime.

Accordingly, OSHA is proposing an 8hour TWA PEL of 0.1 mg/m3, measured as the respirable dust fraction, for coal dust having a respirable quartz fraction of more than 5 percent quartz, and an 8hour TWA PEL of 2 mg/m3, measured as the respirable dust fraction, for coal dust having a respirable quartz fraction of less than 5 percent quartz; these limits are being proposed for workplaces in the construction, maritime, and agriculture industries. The Agency's previous formula limit for silica containing more than 5 percent quartz (respirable fraction) is equivalent to the 0.1-mg/m3 limit in terms of airborne concentration, and the proposed limit in construction and maritime is thus intended merely to simplify the units used to measure and express the limit. OSHA believes that this revision will simplify employee exposure monitoring. For coal dust having a respirable quartz fraction of less than 5 percent, OSHA is

proposing to lower the 8-hour TWA limit from 2.4 mg/m³ to 2 mg/m³ in construction and maritime and to extend this limit to agriculture. Promulgation of these limits will make OSHA's PELs for coal dust consistent across all regulated sectors.

COTTON DUST
CAS: N.A.; Chemical Formula: Not applicable
H.S. No. 2041

In general industry, OSHA's permissible exposure limits (PELs) for cotton dust are: 200 µg/m3 in yarn manufacturing and cotton washing operations; 500 µg/m3 in textile mill waste house operations or in yarn manufacturing using "lower grade washed cotton;" and 750 µg/ms in slashing and weaving operations. There is also a PEL of 1 mg/m3 that applies to cotton waste processing operations (see 29 CFR 1910.1000, Table Z-1-A). These exposure concentrations are averaged over an 8-hour period, as measured by a vertical elutriator or an equivalent instrument. Currently, the construction, agriculture, and maritime sectors have no PELs for cotton dust. The ACGIH TLV*-TWA for cotton dust is 0.2 mg/m3 for lint-free cotton dust with fibers less than 15 microns in length. The NIOSH REL is less than 200 µg/m3 (lint-free cotton dust). OSHA is proposing to establish an 8-hour TWA PEL of 500 µg/ m3 for cotton dust in the construction, agriculture, and maritime industries. Promulgation of this limit will make the PEL for cotton dust in construction, maritime, and agriculture consistent with the PEL for "all other operations" specified in OSHA's cotton dust standard. Also, the Advisory Committee on Construction Safety and Health recommended a 500 µg/m3 PEL for cotton dust in construction.

Cotton is commercially grown in at least 19 States and is a major crop in 14. Most of the crop is harvested and ginned in the fall and early winter; it is processed by domestic and foreign mills on a year-round basis. Hence, storage and transportation are major operations in the cotton industry. The cotton industry of the United States can be divided into several processes: harvesting; ginning; warehousing and compressing of cotton lint; classing and marketing of cotton lint; fabric manufacturing using cotton yarn; reclaiming and marketing of textile manufacturing waste; delintering of cottonseed; marketing and converting of linters; reclaiming and marketing of ginmotes; and batting, yarn, and felt manufacturing using waste cotton fibers and byproducts.

There are no data on the toxicity of cotton dust in animals. In humans, exposure to cotton dust causes byssinosis, a specific respiratory disease whose signs and symptoms are attributable to the action of cotton dust on the respiratory passages. The effects of byssinosis can be temporary or permanent, depending on the exposure and the individual, and can lead in time to chronic obstructive lung disease, primarily chronic bronchitis (Harris et al. 1972; Daum et al. 1974). Initially, the individual notices a tightness in the chest occurring on the first day of the work week. The tightness may be accompanied by a measurable decrease in breathing capacity, as shown by pulmonary function tests. Usually, the condition is mild and temporary at first, tending in time to progress to the stage of bronchitis by the end of the work week. This progression, which is characterized by constriction of the bronchial tubes of the lung, leads to a permanent narrowing of these airways. The individual develops a chronic cough with the production of phlegm and increasing shortness of breath. At this stage, the condition is readily detectable by pulmonary function measurements. Total disability and even death may follow. The description of these detailed symptoms appeared as early as 1908 in the work of Collis (1932).

As a result of the obviously subjective quality of the early symptoms of byssinosis, investigators have, in the past few years, subdivided byssinosis into different categories for purposes of diagnosis and treatment, namely: (a) the reversible symptomatic or physiological condition (sometimes referred to as a reactor state), and (b) the chronic

irreversible lung disease.

Schilling (1955, 1963) distinguished the reversible symptoms of Grade one-half, Grade one, and Grade two byssinosis from permanent incapacity, which he labeled Grade three byssinosis. According to Schilling's classification, byssinosis is graded as follows:

(a) Grade one-half—occasional chest tightness on the first day of the work

week

(b) Grade one—chest tightness and/or breathlessness on Mondays only.

(c) Grade two—chest tightness and/or breathlessness on Mondays and other

days.

(d) Grade three—grade two symptoms accompanied by evidence of permanent incapacity from diminished effort tolerance and/or reduced ventilatory capacity.

In their studies of textile mills in the United States, Merchant et al. (1973) reached the conclusion that exposure to 500 µg/m³ cotton dust would result in a

25 percent prevalence of all grades of byssinosis. These investigators, using the vertical elutriator, found a strong linear association between the prevalence of byssinosis and the airborne concentration of lint-free dust (less than an aerodynamic equivalent diameter of 15 microns). In cotton preparation and yarn areas, exposure to untreated cotton was shown to produce a 3 percent prevalence of byssinosis (all grades) at 50 ug/m3, a 7 percent prevalence at 100 ug/m3, and a 13 percent prevalence at 200 ug/m3. However, OSHA's experience under the cotton dust standard has demonstrated that the prevalence of byssinosis has been reduced substantially more by the cotton dust standard (see 50 FR 51120. Dec. 13, 1985) than these figures would suggest.

Byssinosis is the respiratory disease most commonly associated with exposure to cotton dust, but other diseases such as chronic bronchitis, mill fever, weavers' cough, and mattress makers' fever have also been associated with cotton dust exposure. These diseases and additional studies on byssinosis have been described and their association with cotton dust exposure has been documented extensively in previous Federal Register publications (41 FR 56500–56502; 42 FR 27352–27354; 48 FR 26964–26968; 50 FR

51120).

OSHA's cotton dust standard was based on data demonstrating significant excess risk of byssinosis and other respiratory symptoms in workers exposed to cotton dust in the early 1970s and before. Those data also showed that reductions in exposure substantially reduced risk. Both the Court of Appeals and Supreme Court upheld OSHA's analysis of the studies and OSHA's conclusion that a standard was needed to substantially reduce a significant risk of disease. Cotton dust is, of course, present in agriculture (cotton ginning) and marine transportation operations.

OSHA therefore believes that, in the absence of PELs, workers in agriculture, construction, and maritime are at significant risk of experiencing these adverse health effects. The Agency believes that the proposed limit of 500 µg/m³ as an 8-hour TWA is necessary to significantly reduce these risks of material health impairment among workers in the construction, maritime, and agriculture sectors. Promulgation of these limits will establish PELs for cotton dust in all OSHA-regulated sectors.

The vertical elutriator, though a better measuring device for correlating exposure with health effects, is not practical where area samples cannot be taken retrospectively, and these devices are also bulky. OSHA will permit employers to substitute a respirable dust personal sampler where it is not feasible to use a vertical elutriator. OSHA proposes that in those circumstances where a personal sampler is used, the exposure limit be 1 mg/m³ respirable dust, personal sampler. Evidence in the 1978 rulemaking indicated that such a limit is roughly equivalent to $500~\mu g/m³$ as measured by a vertical elutriator.

ETHYL ACRYLATE

CAS: 140–88–5; Chemical Formula: CH₂ = CHCOOC₂H₅

H.S. No. 1161 OSHA curre

OSHA currently has an 8-hour TWA limit of 25 ppm for ethyl acrylate, with a skin notation, in the construction and maritime industries. There is no limit in agriculture. NIOSH has no REL for this substance. The ACGIH has a TLV*-TWA of 5 ppm, a TLV*-STEL of 25 ppm, and a skin notation for ethyl acrylate. The Agency is proposing an 8-hour TWA PEL of 5 ppm and a 15-minute STEL of 25 ppm, with a skin notation, for ethyl acrylate in the construction, maritime, and agriculture industries. Promulgation of these limits will make the PELs for this substance consistent across all OSHA-regulated sectors.

Ethyl acrylate is a colorless liquid with an acrid odor. This substance is used in the manufacture of acrylic resins and in emulsions and solution polymers for the surface coating of textiles, paper, and leather. It is also used to produce acrylic fibers, adhesives, and binders and as a fragrance and flavoring agent (ACGIH 1986, p. 240).

Ethyl acrylate produces irritation of the skin, eyes, mucous membranes, and respiratory system (Dreisbach 1974/Ex. 1–896). The oral LD $_{50}$ in rats is 800 mg/ kg, and the 4-hour LC50 in the same species is 2180 ppm (RTECS 1991). In rabbits, the dermal LDso is 1834 mg/kg (RTECS 1991). In contact with the eyes or skin of rabbits, ethyl acrylate produces mild irritation (RTECS 1991). Animal studies indicate that severe chronic effects may result from exposure to this substance. Rats exposed to levels of 70, 300, or 540 ppm of ethyl acrylate for up to 30 days showed accelerated mortality and pathologic changes in the lungs, liver, and kidneys. In those animals that developed pneumonia, renal and hepatic lesions were also seen. In a parallel study, rats, rabbits, and guinea pigs who were subjected to ethyl acrylate concentrations in excess of 75 ppm for 50 seven-hour inhalation periods exhibited pulmonary edema before death and had degenerative changes in the heart, liver, and kidneys

at autopsy (Treon, Sigmon, Wright, and Kitzmiller 1949/Ex. 1-769). Miller et al. (1980, as cited in ACGIH 1986/Ex. 1-3, p. 240) reported that rats and mice exposed to 75 or 225 ppm for 8 hours per day for 30 days developed nasal lesions and other degenerative inflammatory changes in the nasal structure. In other studies, rats and mice administered 100 or 200 mg/kg ethyl acrylate by gavage five times per week for 103 weeks developed inflammation and hyperplasia of the forestomach in addition to squamous cell carcinomas and papillomas in the same area (NTP 1983b). A recent study (Moore, Amtower, Doerr, Brock, and Dearfield 1988) has shown that ethyl acrylate is genotoxic in mammalian test systems.

In a study by Nemec and Bauer (1978, as cited in ACGIH 1986/Ex. 1-3, p. 240), human volunteers experienced drowsiness, headache, and nausea after prolonged inhelation exposures to this substance at 50 to 75 ppm. Opdyke (1975/Ex. 1-922) reported that the application of a 4-percent concentration of ethyl acrylate produced skinsensitization reactions in 10 out of 24 volunteers. A recent study (Condesalazar, Guimaraens, and Romero 1988) has shown that occupational exposure to ethyl acrylate is associated with the development of allergic contact dermatitis in as many as 12 percent of exposed workers. Another recent study in chemical plant workers (Schwartz, Doty, Monroe, Frye, and Barker 1989) showed that exposure to ethyl acrylate in the work environment is associated with a decrement in olfactory ability, although the clinical significance of this finding is unclear.

In construction, maritime, and agriculture, OSHA is proposing an 8hour TWA PEL of 5 ppm, a 15-minute STEL of 25 ppm, and a skin notation for ethyl acrylate. The Agency preliminarily concludes that these limits will protect workers in these sectors from the significant risk of respiratory tract irritation, skin sensitization, and nausea and drowsiness associated with exposure to this substance. The Agency considers these adverse effects material impairments of health and believes that the proposed PELs are necessary to substantially reduce these risks. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

FERROVANADIUM DUST CAS: 12604-58-9; Chemical Formula: FeV H.S. No. 1177

OSHA currently has a limit of 1 mg/ m³ as an 8-hour TWA for ferrovanadium dust in the construction and maritime industries. There is no limit in agriculture. The ACGIH has a TLV*-TWA limit of 1 mg/m3 with a TLV0-STEL of 3 mg/m3, and NIOSH has a 10hour REL for this substance (measured as vanadium). The Agency is retaining its 8-hour TWA PEL of 1 mg/m3 in construction and maritime, proposing to add a STEL of 3 mg/m3 in these sectors, and proposing to extend both limits to agriculture. NIOSH concurred (Ex. 8-47, Table N1) with these limits when the Agency recently established them in general industry.

Ferrovanadium dust takes the form of dark, odorless, solid particles. It is generated in the preparation of steel that contains vanadium (ACGIH 1986, p.

269).

In addition to respiratory effects, ferrovanadium dust causes mild eye and nose irritation. Roshchin (1952/Ex. 1-1166) reported that no acute intoxication occurred in animals exposed to ferrovanadium dust at concentrations as high as 10,000 mg/m3; however, serious chronic pulmonary changes were observed after short-term exposures (one hour) on alternate days for two months to concentrations in the 1000- to 2000-mg/m3 range. These pulmonary changes consisted of chronic bronchitis and chronic lung inflammation (Roshchin 1952/Ex. 1-1168).

Workers exposed to unspecified concentrations of this dust developed mild irritation of the eyes and respiratory tract (Roberts 1965). -OSHA is retaining its 8-hour TWA PEL of 1 mg/ m3 in construction and maritime, proposing to add a 3 mg/m3 STEL in these two sectors, and proposing to extend both limits to agriculture. The Agency preliminarily concludes that the combined TWA limit and STEL will substantially reduce the significant risk of eye and upper respiratory tract irritation and of chronic pulmonary damage shown to be associated with exposures to this substance. OSHA considers these adverse health effects to be material impairments of health and believes that the proposed PELs are necessary to substantially reduce this risk. In addition, promulgation of these limits will make OSHA's PELs for ferrovanadium dust consistent across all OSHA-regulated sectors.

FIBROUS GLASS, INCLUDING REFRACTORY CERAMIC FIBERS CAS: None; Chemical Formula: None H.S. No. 1178

Fibrous glass is used primarily for thermal and acoustical insulation of residential and commercial buildings. Refractory ceramic fibers (RCF) are primarily used for high temperature

insulation applications, including blanket linings for industrial furnaces and vacuum-formed parts for specialty products with high-temperature tolerances. There are currently no specific OSHA limits governing occupational exposure to fibrous glass or RCF, although these substances are covered by the Agency's 15 mg/m3 (5 mg/m3 respirable) 8-hour TWA limit for all inert dusts and particulates. The ACGIH (1986/Ex. 1-3) has a 10 mg/m3 TLV®-TWA for fibrous glass. NIOSH (1977/Doc. H-043) recommended a 5 mg/m3 8-hour TWA limit for total dust and a 3 fibers/cc limit for airborne fibers less than 3.5 µm in diameter and longer than 10 µm in length. OSHA is proposing an 8-hour TWA PEL of 1 f/cc for fibrous glass, including RCF, in general industry and in the construction. maritime, and agricultural industries.

Fibrous glass is used primarily for thermal and acoustical insulation of residential and commercial buildings. Fibrous glass is produced either as glass wool or glass filament (IARC 1988, Vol. 43). Glasswool is produced by drawing, centrifuging, or blowing molten glass and compromises cylindrical fibers of relatively short length (compared to filaments) (Boyd and Thomason 1980; McCrone 1980). Glass filaments are continuously drawn or extruded from molten glass. This class of materials includes longer, large-diameter filaments for textile and reinforcing applications as well as fine-diameter filaments (Mohr

and Rowe 1978).

In the production of glass fibers, finely powdered sand is used as the major source of silica, and kaolin clay and synthetic aluminum oxides are the most common sources of aluminum. Boric oxide is introduced primarily from colemanite (a natural calcium borate), boric acid, and boric acid anhydride. Powdered dolomite [CaMg(COs)2] or burnt dolomite (MgO*CaO) is used to introduce magnesium oxide (magnesia) and calcium oxide. Uncalcined and calcined limestone are used as magnesia-free sources of calcium oxide. Fluorspar (CaF2) is used to introduce fluoride. Sodium sulfate is added to the glass mixture as a firing agent and to assist in dissolving residual grains of sand. Iron oxide (Fe2Os) may be added to assist the fiber-drawing process (Loewenstein 1983; Harben and Bates 1984).

Ceramic fibers comprise a wide range of amorphous or crystalline synthetic mineral fibers characterized by their refractory properties (i.e., stability at high temperatures) (IARC 1988, Vol. 43). Ceramic fibers are typically made of alumina, silica, and other metal oxides

or, less commonly, of nonoxide materials, such as silicon carbide (Arledter and Knowles 1964). Most ceramic fibers are composed of alumina and silica in an approximate 50/50 mixture. Monoxide ceramics, such as alumina and zirconia, are composed of at least 80 percent of one oxide, by definition; usually, they contain 90 percent or more of the base oxide, and specialty products may contain virtually 100 percent. Other ceramic fibers prepared for special applications may incorporate thoria, magnesia, beryllia, titania, hafnia, yttria, or potassium titinate. Nonoxide specialty ceramic fibers, such as silicon carbide, silicon nitride, and boron nitride, have also been produced (Arledter and Knowles 1964; Miller 1982; U.S. Environmental Protection Agency 1986).

Non-RCF Fibrous Glass Nonmalignant Respiratory Disease

Human Studies-

A number of epidemiological studies and case reports of workers exposed to fibrous glass have shown that these workers have an excess risk of nonmalignant respiratory disease (NMRD). A review of 691 physicians' reports of adverse effects caused by exposure to fibrous glass identified 68 reports of upper respiratory tract symptoms including rhinitis, sinusitis, pharyngitis, and laryngitis in workers exposed for only one or 1.5 years [Milby and Wolf 1969, as cited in NIOSH 1977/ Doc. H-043, p. 23). Irritation and inflammation of the nasopharyngeal region and upper respiratory tract have also been reported in a number of early studies (Champeix 1945, as cited in IARC 1988/Doc. H-043, p. 136; Trumper and Honigsberg 1946, as cited in NIOSH, 1977/ Doc. H-043, p. 29; Roche 1947, as cited in IARC 1988/Doc. H-043, p.136; Cirla 1948, as cited in IARC 1988/Doc. H-043, p. 136; Mungo 1960, as cited in IARC 1988/Doc. H-043, p. 136). Later reports of nasopharyngeal irritation include those of Müller et al. (1980, as cited in IARC 1988/Doc. H-043, p. 136) and Maggioni et al. (1980 as cited in IARC 1988/Doc.H-043, p. 136).

NIOSH (1990/Doc. H-043) conducted a Health Hazard Evaluation of a factory which manufactures fibrous glass for thermal and acoustical insulation. The evaluation was instigated by a request which stated that employees were experiencing nose bleeds, skin rashes, and respiratory problems. Potential exposures identified in the request were fibrous glass and formaldehyde. The full-shift personal exposure levels of formaldehyde ranged from 0.07 to 0.41 ppm, with a mean exposure of 0.11 ppm.

Only two of the personal samples were greater than 0.1 ppm (0.14 and 0.41). The authors stated, however, that the validity of the 0.4 result was questionable when compared to all other personal and area samples collected for this worker. Respirable fibrous glass concentrations ranged from less than 0.01 to 0.07 f/cc. The workers were not following proper work practices to reduce or prevent skin irritation as described in the appropriate Material Safety Data Sheets. They were also not wearing appropriate work clothes (long-sleeve shirts, goggles, and gloves).

Approximately 50 percent of the workers completed a medical questionnaire. The following effects were reported: chronic cough (cough on most days for a period of 3 months or more), 61 percent; phlegm, 53 percent; some degree of shortness of breath, 61 percent; highest level of severity for shortness of breath (having to stop for breath when walking at own pace on level ground), 10 percent; chest tightness, 61 percent (many on all workdays); wheezing, 49 percent. Additional signs and symptoms reported to be present at work two or more times per week included eye irritation, 51 percent; nose irritation, 50 percent; cough, 42 percent; sneezing, 22 percent; sore throat, 10 percent; and nose bleeds, 4 percent.

Several studies report effects on the bronchi. Murphy (1961, as cited in NIOSH 1977/Doc. H-043, p. 28) reported bronchiectasis and multiple focal abscesses in the terminal bronchioles and peribronchial parenchyma, as well as slight pulmonary fibrosis in an electrical worker who dismantled fibrous glass-insulated appliances. Bayliss et al. (1976, as cited in NIOSH 1977 Doc. H-043, Ex. 1-3, p. 37) studied a group of 1,448 fibrous glass production, packing, and maintenance workers who had been initially employed during the period January 1, 1940 through December 31, 1949 and who had been employed for at least 5 years by June 1, 1972 in the one major fibrous glass construction products manufacturing plant studied. The current mean fiber concentration was 0.08 f/cc. The range was 0.01 to 0.83. Although only limited historical dust measurements were available, it did appear that respirable fiber concentrations were also low about 10 years prior to the present industrial hygiene survey. A statistically significant excess risk of NMRD was found among these workers. In addition, bronchiectasis was found at autopsy in 6 of the 19 fatal cases (Bayliss, written

report, 1977, as cited in NIOSH 1977/ Doc. H-043, p. 38).

Enterline and Henderson (1975/Doc. H-043) studied 416 retirees who had worked in six plants that manufactured fibrous glass insulation. A slight, non-statistically significant increase in deaths from NMRD was observed. Out of 35 workers who had retired early due to disability, chronic bronchitis was observed in three workers and expected in 0.5. The authors felt that the latter finding might be important but they pointed out that the numbers were small and that chronic bronchitis is not a well-defined disease entity in many instances.

An increased frequency of bronchitis that was directly related to duration of exposure to synthetic mineral fibers (SMF) has been observed in a group of 135,000 construction workers (Engholm and von Schmalensee 1982/Doc. H-043). The calculated standard ratios for workers in each smoking history category indicated a positive association between bronchitis and exposure to SMF. Among nonsmokers, 77 percent of all cases of bronchitis in workers with long exposure to SMF were attributable to the exposure. The corresponding percentage in present smokers was 28 percent. The authors concluded that there is a clear association between bronchitis and SMF exposure in the construction industry.

Tomasini et al. (1986, as cited in IARC 1988/Doc. H-043, p. 136) have reported on the occurrence of parenchymal involvement of lung tissue in four of seven workers with long-term exposure to fibrous glass in manufacturing. Three of these workers had pulmonary fibrosis and one had both fibrosis and parenchymal involvement. Three workers exposed to fibrous glass during manufacture for 9 to 17 years had respiratory distress and one showed slight pleural thickening on x-ray examination (Chiappini et al. 1981, as cited in IARC 1988/Doc. H-043, p. 136).

Enterline and co-workers (Enterline et al. 1983, Doc. H-043, Ex. 1-17; Enterline et al. 1986, as cited in Vu 1988/Doc. H-043, p. 76; Enterline et al. 1987/Doc. H-043; Enterline 1987/Doc. H-043) studied 16,661 white male workers employed in 17 synthetic mineral fibers plants and who had 1 or more years of experience in production or maintenance during the period 1945-1963. This cohort consisted of 14,815 workers in 11 fibrous glass plants (6, glass wool only; 3, glass filament only; 2, glass wool and glass filament) and 1,846 workers in 6 mineral wool plants. The SMR for nonmalignant respiratory disease (excluding influenza and pneumonia) for all synthetic mineral

fiber workers was statistically significant. In epidemiological studies, the SMR results from the comparison of the number of observed deaths in the study population with the number of expected deaths in a larger population with stable rates. Thus the SMR is equal to the number of observed divided by the number of expected deaths. By convention, this ratio is then multiplied by 100 to get the reported ratio. If this ratio is greater than 100, it means that more deaths are observed in the smaller population than would be expected based on rates in the larger (standard) population. If the ratio is less than 100. fewer deaths are observed than expected. The SMR was 132.3 (p<0.01) when U.S. rates were used for comparison and 134.1 (p<0.01) when local rates were used. When a difference that is observed between two groups is judged to be statistically significant (e.g., p < 0.01), this means that differences as large as, or larger than, that observed would occur by chance alone less than (for this example) 1 percent of the time. For workers with greater than 20 years since first exposure in plants which manufactured both fibrous glass wool and filament, there was a statistically significant increase in NMRD (excluding influenza and pneumonia) (SMR 141.8, p < 0.01, U.S. comparison). For workers in one of these plants, in which the cohort size was 5,651, the SMR was 137.5 (p<0.01, U.S. comparison). The mean average exposure concentration for all the fibrous glass plants was 0.039 f/cc and the maximum was 1.5 f/cc. In the plant just cited, the mean exposure concentration was 0.067 f/cc and the maximum was 1.5 f/cc. Among workers in this group who were "ever exposed" to small-diameter fibers, there was a slight nonsignificant increase in NMRD with time since first exposure.

Marsh et al. (1990/Doc. H-043) completed a follow-up to 1985 of the Enterline et al. cohort. The SMR for nonmalignant respiratory disease (excluding influenza and pneumonia) for all MMMF workers was 129.4 (p < 0.01) when U.S. rates were used for comparison. A breakdown of NMRD rates by process showed no increase for fibrous glass workers when rates were compared to local rates. National rates were not used for comparison. Several studies have observed the occurrence on x-ray examination of opacities in the lungs of a limited number of workers in the fibrous glass manufacturing industry (Nasr et al. 1971, as cited in NIOSH 1977/Doc. H-043, p. 35; Valentin et al. 1977, as cited in IARC 1988/Doc. H-043, p. 135; Weill et al. 1983, 1984, as cited in

IARC 1988/Doc. H-043, p. 135; Hill et al. 1973, 1984, as cited in IARC 1988/Doc. H-043, p. 135).

Animal Studies

In animal studies, exposure to non-RCF fibrous glass by several routes has been shown to cause respiratory effects. Schepers and Delahant (1955 as cited in NIOSH 1977/Doc. H-043, p. 41) continuously exposed guinea pigs and rats to glass wool (nominal diameter 6µm; concentration 5.0 to 5.2 mg/m3) by the inhalation route for 20 months and subsequently to "glass cotton" (maximum diameter 3µm; concentration 1.1 to 2.5 mg/m³) for 20 and 4 months, respectively. After 4 months of exposure, the guinea pigs had considerable epithelial hyperplasia (abnormally increased cell number) and cellular desquamation (cells sloughed off) in the smaller bronchioles and cellular infiltration of alveolar walls, with hyperplasia of parenchymal pulmonary lymph nodes (which indicates a reaction of the immune system). Atelectatic (areas of collapsed alveoli) were also present. At the 40th week of exposure, dust-reaction foci were detected that were related to the atelectatic areas. Lung abscesses were found in 10 percent of the rats. These effects indicate a toxic effect on the respiratory tract.

Botham and Holt (1971, as cited in NIOSH 1977/Doc. H-043, p. 43) reported the production of ferruginous bodies in guinea pigs within 2-5 days after inhalation for one 24-hour period of a "high" (not further specified) concentration of glass fibers (<20 µm length; <1 µm diameter). Ferruginous bodies are protein-coated inclusions which form around fibrous mineral particles. When these bodies form around asbestos fibers they are often called "asbestos bodies." Ferruginous bodies are observed in humans exposed to asbestos. Alveolar lipoproteinosis, another indictor of lung toxicity, developed in rats and hamsters treated by inhalation for 90 days with 400 mg/ m^3 glass fibers $< 2 \mu m$ in length (Lee et al. 1979, as cited in IARC 1988/Doc. H-043, p. 130; Lee et al. 1981, as cited in Vu 1988/Doc. H-043, p. 52; Lee and Reinhardt 1984, as cited in IARC 1988/ Doc. H-043, p. 130). The fibers had small aspect ratios (3:1) and only 7 percent were considered fibrous in shape. Very slight alveolar interstitial fibrosis occurred in a few old animals. Pulmonary inflammation has been reported in rats exposed by inhalation to fibrous glass (diameter 0.1-0.6 µm) for 6 months (Miller 1980, as cited in IARC 1988/Doc. H-043, p. 129).

Fibrosis is seen in experimental animals exposed to mineral fibers. For example, fibrosis is seen in response to asbestos exposure. In humans exposed to asbestos, diffuse interstitial fibrosis and fibrosis of the pleura are observed as components of the disease known as asbestosis. When it becomes massive, fibrosis causes the obliteration of the respiratory capacity of lung. A few of the oldest rats in a group exposed for 24 months to 100 mg/m3 of fibrous glass with an average diameter of 0.5 µm and an average length of 10 µm developed some foci of septal collagenous fibrosis, although most developed only a normal 'dust reaction' (Gross et al. 1970a, as cited in IARC 1988/Doc. H-043, p. 130). Johnson and Wagner (1980, as cited in Vu 1988/Doc. H-043, p. 53) treated rats by inhalation exposure with 10 mg/m3 of glass microfibers, resin-coated glass wool, or uncoated glass wool for 50 weeks. Focal fibrosis was observed. Very low levels of fibrosis were seen in rats and hamsters exposed by nose-only inhalation to fibrous glass ranging in diameter from 0.45 µm to 6.1 µm in concentrations up to 3000 f/cc for 2 years (Smith et al. 1984, 1987, as cited in IARC 1988/Doc. H-043, p. 131). Slight septal fibrosis was observed in rats exposed to both glass microfibers (diameter <1 µm) and thicker fibrous glass (diameter <1-3 µm) at concentrations of 5 mg/m3 for up to 2 years (Le Bouffant et al. 1987, as cited in IARC 1988/Doc. H-043, p. 131).

Baboons developed focal peribronchiolar fibrosis after inhalation exposure to fibrous glass with a median diameter of 0.5-1.0 µm and a length of 6 um in a concentration of 1,122 f/cc (7.5 mg/m³) for up to 30 months (Goldstein et al., 1983, 1984, as cited in IARC 1988/ Doc. H-043, p. 131 and Vu 1988/Doc. H-043, p.54). The lesions were similar to those produced by crocidolite asbestos. Cynomolgus monkeys and Fischer 344 rats exposed to fibrous glass dust for 18 and 21 months, respectively, at concentrations of 5 or 15 mg/m3 showed no fibrosis but did have pulmonary macrophage aggregates and granulomas (indicative of a foreign body reaction) containing fibrous glass. In addition, the rats had pleural plaques (Mitchell et al., 1986, as cited in Vu 1988/Doc. H-043, p. 53). Animals exposed to fibrous glass by intratracheal instillation or intrapleural or intraperitoneal injection have also exhibited fibrotic and other responses.

The intratracheal instillation of fibrous glass has been shown to produce an inflammatory response in rats and hamsters (Gross et al., 1970 a, b, as cited in I ARC 1988/Doc. H-043, p.131; Sykes et al., 1983, as cited in IARC 1988/Doc.

H-043, p. 129) and focal areas of pneumonitis (Vorwald et al. 1951, as cited in IARC 1988/Doc. H-043, p. 131) or focal atelectasis (Schepers and Delahant 1955, as cited in IARC 1988 Doc. H-043, p. 131) in guinea pigs. Wenzel et al. (1969, as cited in IARC 1988/Doc. H-043, p. 131) demonstrated the production of pulmonary fibrosis by the intratracheal instillation of fibrous glass in rats. Kuschner and Wright (1976, as cited in NIOSH 1977/Doc. H-043, p. 48; Wright and Kuschner 1977, as cited in IARC 1988/ Doc. H-043, p. 131) treated guinea pigs with glass fibers of various dimensions by intratrecheal instillation. The diameters of the fibers varied from <0.3 μm to 1.0 μm. Lengths were either short (<10 µm) or long (>10 μm). All long fibers produced interstitial fibrosis, while short fibers did not. Syrian hamsters treated by intratracheal instillation with fibrous glass of various diameters or crocidolite asbestos had developed increased collagen deposition and pulmonary fibrosis when observed at 11 months after instillation. The degree of the effect was as follows: asbestos (0.24 µm diameter) > glass microfibers (0.2 µm diameter) > commercial glass fibers (2.3 µm). No fibrosis was seen in hamsters treated with fibers having diameters of 3-4 µm (Pickrell et al. 1983, as cited in Vu 1988/ Doc. H-043, p. 55).

Smith et al. (1986) treated rats by intratracheal instillation with glass fibers (mean diameter 0.45 µm), crocidolite asbestos, or saline once a week for five weeks. The incidence of marked lung fibrosis was 32 percent for those rats treated with glass fibers, 96 percent for those treated with asbestos, and 0 percent for the saline controls. Massive fibrosis, comparable to that seen in asbestos controls, has also been produced by glass fibers given to mice by intrapleural injection (Davis 1976, as cited in Vu 1988/Doc. H-043, p. 56). Mice were treated with fibers which were either 3.5 µm or 0.05 µm in diameter and either <20 µm or 100 µm in length. Fibers of either diameter that were >100 µm in length produced massive fibrosis. Fibers of either diameter that were <20 μm in length produced discrete granulomas with minimal fibrosis. Intraperitoneal injection of long glass fibers with mean diameters of 0.05 to 0.1 µm or 2.5 to 4 µm has also been shown to cause fibrosis in mice (Davis 1972, as cited in IARC 1988/Doc. H-043, p. 132). Peritoneal fibrosis was also produced in a dose-related manner in rats treated by intraperitoneal injection with glass fibers with an average diameter of 0.5 µm with 72 percent being <5 μm in length (Pott et al. 1974, as

cited in Vu 1988/Doc. H-043, p. 56). Rats injected with glass fibers with a mean diameter of 0.45 µm also demonstrated a peritoneal fibrotic response (Smith et al. 1986, as cited in Vu 1988/Doc. H-043, p. 56).

Carcinogenicity

Human Studies

A number of epidemiological studies conducted on workers exposed to fibrous glass have shown that these workers have an excess risk of lung and other respiratory tract cancers. In some cases the excess risk has been small and the studies are subject to conflicting interpretations.

interpretations.

Morgan et al. (1984, as cited in IARC 1988/Doc. H-043, p. 138) studied 4,399 men who had worked for at least 10 years and were employed at some time during 1968-1977 at one or more fibrous glass plants owned by a single U.S. company. The SMR for respiratory cancer for the total cohort was 136. For men with 20 years or more of employment and who were first exposed 30 years or more ago, the SMR was 177. For lung cancer, the job categories of textile forming/wool forming and fabrication had SMRs of 181 and 132,

respectively. Moulin et al. (1986, as cited in IARC 1988/Doc. H-043, p. 141) studied 1,374 men who had worked in a French fibrous glass factory for at least 1 year and who were employed there at any time during 1975-1984. The Standardized Incidence Ratio for upper respiratory and alimentary tract cancers was 218. There was a nonsignificant increasing trend in incidence ratio with increasing duration of employment. Another study (Shannon et al. 1987, as cited in IARC 1988/Doc. H-043, p. 141) examined the mortality experience of 2,557 men who had worked 90 days or more and had been employed in 1955-1977 in a Canadian glass wool plant. The SMR for lung cancer was 199 (p<0.05). For those workers with 5 or more years of exposure and with 10 or more years since first exposure, the SMR for lung cancer was 182. Although historical exposure data were not available. samples taken since 1978 suggested that fiber concentrations were rarely greater than 0.2 fiber/cm3, with mean levels in most areas less than 0.1 fiber/cm3.

Two studies, one in the United States and one in Europe, have examined the mortality experience of very large groups of workers in fibrous glass plants. Enterline et al. (1987/Doc. H-043) studied 16,661 white male workers from 17 synthetic mineral fibers plants who had 1 or more years of experience in production or maintenance during the

period 1945-1963. This cohort consisted of 14,815 workers in 11 fibrous glass plants (6, glass wool only; 3, glass filament only; 2, glass wool and glass filament) and 1,846 workers in 6 mineral wool plants. The SMR for all synthetic mineral fiber workers for respiratory system cancers was 115.6 (p < 0.01) when U.S. rates were used for comparison and 109.1 when local rates were used. For deaths that occurred during the period 1978-1982, the SMRs were 129.7 (U.S.) (p<0.01) and 112.7 (local). For workers with fewer than 20 years since first exposure, the SMRs for respiratory system cancer were 93.8 (U.S.) and 99.6 (local). For workers with greater than 20 years since first exposure, the SMRs were 124.3 (U.S.) (p<0.01) and 112.3 (local). More specifically, for workers with more than 20 years since first exposure, SMRs for the category that included bronchus. trachea, and lung cancer were 125.4 (U.S.) (p<0.01) and 112.7 (local) (p < 0.05).

A significant increase in respiratory cancer compared with U.S. rates (SMR 129.5, p<0.01) but not compared with local rates (SMR 110.6) was also observed in workers employed for more than 20 years in the two fibrous glass plants that manufactured both glass wool and glass filament. No increase was seen in workers employed for fewer than 20 years. The increase appeared to be accounted for primarily by the increased rate (SMR 128.3, U.S., p < 0.1) seen in one plant that employed 5,651 workers. In fact, the experience of this plant drives the results of the overall study to some extent since, of the 301 deaths from respiratory cancer 20 years or more since first exposure, 147 occurred in workers from this plant. The authors of this study believe that the use of local rates for comparison is more appropriate because they tend to adjust for social, economic, ethnic, and cultural factors. Thus they concluded that respiratory cancer rates were not significantly increased in this cohort. However, other scientists believe that the use of national rates is more appropriate because local rates are affected by local conditions, including other employment in the area. The use of local rates, therefore, requires the demonstration that some area factor and not an employment factor is influencing local rates.

A further subdivision of "time since first exposure" revealed that SMRs for fibrous glass wool workers increased with time since first exposure. Also, respiratory cancer SMRs were significantly increased overall for workers in plants that manufactured

both glass wool and glass filament (SMR 121.1, p<0.05, U.S.; SMR 109.7, local) For workers in these plants who had 30 years of exposure since first exposure. SMRs were 137.8 (U.S.) (p<0.01) and 110.8 (local). Although stating that support for the notion that exposure to synthetic mineral fibers is related to respiratory cancer comes from patterns in mortality excess as they relate to probable fiber exposure, the authors point out that several features of the data are not consistent with a causal relationship between respiratory cancer and SMF exposure. These included a lack of relationship with duration of exposure and inconsistent relationships with time since first exposure. The authors also suggest that some other contaminant in the workplace may have caused the excess respiratory cancer. However, these studies lacked data on exposure to workplace contaminants other than fibers.

In the glass wool plants, fiber concentrations to which workers were exposed were estimated to range from 0.005 fiber/cm³ in one plant to 0.293 fiber/cm³ in a plant that produced small-diameter fibers. The mean exposure concentration was 0.039 f/cc. The highest individual average fiber exposure level estimated for any member of this cohort was 1.5 fiber/cm³. For the plant with the large cohort (5,651) mentioned above, the mean exposure concentration was 0.067 f/cc. The maximum concentration in that plant was 1.5 f/cc.

In an attempt to adjust for cigarette smoking, a 'case-control within a cohort' study of glass wool workers was also included. Cumulative exposure to glass wool was not a significant variable, while age at exit, year of birth, and smoking were statistically significant (p<.05). However, the IARC Working Group believes that the results of this case-control study may have been affected by differences in the methods of information collection used to obtain information on smoking, since smoking histories for most cases were obtained from surrogate respondents, whereas those for the majority of the controls were obtained from the respondents themselves, an approach that introduces the possibility of bias (IARC, 1988/ Doc. H-043, p. 140)

These authors also made a separate analysis of 7,586 workers in four plants that produced small-diameter fibers (<3 μ m). SMRs for respiratory cancer were 132.9 (U.S.) and 123.7 (local) for those exposed and 114.7 (U.S.) and 104.8 (local) for those never exposed. Although these overall increases were not statistically significant, the SMRs

were significant for deaths occurring during the period 1978–1982, with 219.4 (U.S.) (p <0.05) and 197.7 (local) (p <0.05). SMRs also increased with time since first exposure. The authors concluded that these data were consistent with the notion that work in departments that produced small diameter fibers was associated with respiratory cancer.

Marsh et al. (1990/Doc. H-043) completed a follow-up (to the year 1985) of the Enterline et al. cohort. The SMR for respiratory system cancers for all SMF workers was 120.5 (p < 0.01) when U.S. rates were used for comparison and 112.1 (p < 0.05) when local rates were used. The SMRs for cancers of the bronchus, lung, and trachea were 121.5 (U.S.; p < 0.01) and 112.5 (local; p < 0.05). For workers exposed to fibrous glass only in the two plants that manufactured both glass wool and glass filament, the SMR was 115.6 (p < 0.05) for those with more than 20 years since first employment, as compared with local rates. (The SMRs as compared with national rates were not provided.) A further subdivision of cases by time since first exposure suggested a trend for those workers exposed to fibrous glass in "both" and combined wool and "both" plants. Also, respiratory cancer SMRs were significantly increased overall for workers in plants that manufactured both glass wool and glass filament (SMR 114.0, p <0.05, local) and in combined wool and "both" plants (SMR 111.8, p < 0.05, local). For workers in "both" plants who had 30 years since first exposure, the SMR was 119.9 (p <0.05, local).

Simonato et al. (1987/Doc. H-043, pp. 603-623) studied 24,609 workers producing rock wool/slag wool, glass wool, or glass filament in 13 European factories in seven countries. Four of these factories produced glass wool. Among glass wool workers, the SMRs for lung cancer were 127 (p < 0.05) (compared with national rates) and 103 (local). Workers whose time since first exposure was greater than 30 years had an SMR of 173 (p < 0.05). There was an increasing trend in SMRs for lung cancer with time since first exposure, but this trend was not statistically significant.

The average fiber concentration in these plants, on the basis of measurements taken in 1977–1980, was <0.1 fiber/ml (range, 0.01 to 1.00 fiber/ml). The highest concentrations were associated with the manufacture of special fine fiber earplugs. In the main production and secondary production groups, the concentrations ranged from 0.01 to 0.16 f/cc (Cherrie et al., 1986/Doc. H-043, Ex. 1-4, pp. 18-25). Although no

historical exposure data exist, Cherrie et al. estimated that early technological phase production techniques probably produced airborne fiber levels similar to those in the late phase measured. The average plant median for fiber length ranged from 8 to 15 μ m, and the corresponding median diameters ranged from 0.7 to 1 μ m.

Animal Studies

Numerous studies have been done using several species of animals and with fibrous glass administered by several routes. The inhalation route of exposure has been used in five experiments with rats and one experiment each with hamsters and baboons. In all of these studies there was no statistically significant increase in the incidence of lung or pleural tumors. In most experiments with rats, however, a few respiratory tract tumors occurred. In all of these inhalation experiments, one of the intended positive controls, crocidolite asbestos, also produced no statistically significant increased incidence of lung tumors. It is thought that rodent inhalation tests may be less sensitive than tests by other routes for evaluating the carcinogenicity of fibers because the qualitative and quantitative aspects of fiber deposition and retention are substantially different from those in humans. Fibers relevant for human disease may never reach the target organ in sufficient quantities. Other routes of exposure, such as intratracheal instillation and intrapleural and intraperitoneal administration, bring fibers into direct contact with the same target tissues as would occur in humans (IARC 1989/Doc. H-043, p. 34).

In two experiments with rats and one experiment with hamsters, animals were treated with glass wool (mean fiber diameter < 0.3 µm) by repeated intratracheal instillation. In one rat experiment, a statistically significant increase in the incidence of lung tumors was observed (Pott et al. 1987, as cited in IARC 1988/Doc. H-043, p. 91). In the other rat experiment, no respiratory tract tumors were observed; however, the tumor response to the positive control, crocidolite, was also low in this study (Smith et al. 1987, as cited in IARC 1988/Doc. H-043, p. 91). In the experiment with hamsters, however, both lung tumors and mesotheliomas were observed (Pott et al. 1984a, as cited in IARC 1988/Doc. H-043, p. 91).

There have been five studies with rats and one study with mice in which the route of administration was intrapleural implantation or injection. Pleural tumors were found in four of the rat studies.

The tumor incidence varied with the fiber size (Wagner et al. 1973, 1976, 1984. as cited in IARC 1988/Doc. H-043, p. 93; Monchaux et al. 1981, as cited in IARC 1988/Doc. H-043, p. 93; Stanton et al. 1977, 1981, as cited in IARC 1988/Doc. H-043, p.93). No tumors were observed in mice, but there was a relatively short observation time and a low response in positive controls (Davis 1976, as cited in IARC 1988/Doc. H-043, p. 92). Stanton et al. (1977, 1981, as cited in IARC 1988/ Doc. H-043, p. 93) treated rats with a single implantation of one of 72 different types of synthetic and natural fibers (including asbestos). Nineteen of the fibers were fibrous glass. The investigators found that incidences of pleural mesothelioma ranged from 0/28 to 20/29 and correlated with fiber size rather than physicochemical properties. They observed that the most carcinogenic fibers were those <1.5 µm in diameter and >8 µm in length. Thus, these studies demonstrated that glass fibers with length and diameter distributions comparable to those of asbestos were as carcinogenic as asbestos by intrapleural implantation.

Injection of glass wool into the peritoneal cavity of rats produced mesotheliomas or sarcomas in all eight studies with rats (Pott et al. 1976, 1984b, 1987, as cited in IARC 1988/Doc. H-043, pp. 95-96; Muhle et al. 1987, as cited in IARC 1988/Doc. H-043, p. 96; Smith et al. 1987, as cited in IARC 1988/Doc. H-043, p. 96; Smith et al. 1987, as cited in IARC 1988/Doc. H-043, p. 96; Smith et al. 1987, as cited in IARC 1988/Doc. H-043, p. 96; Smith et al. 1987, as cited in IARC 1988/Doc. H-043, p. 96; Smith et al. 1987, as cited in IARC 1988/Doc. H-043, p. 97, as cited in IARC 1988/Doc. H-043, p. 98, p

043, p. 97).

Refractory Ceramic Fibers Nonmalignant Respiratory Disease

Human Studies

RCF production workers are the subject of an ongoing epidemiological study being conducted by the University of Cincinnati. In this longitudinal morbidity study, workers at five RCF manufacturing facilities are being evaluated. Interim results of this study (TIMA, 1990a/Doc. H-043) showed RCF exposure TWAs that ranged from < 0.01 to 1.57 f/cc. Approximately 30 percent of the RCF exposed workers had between 10 and 20 years of exposure, and 4 percent had greater than 20 years of exposure. With regard to morbidity, the prevalence of respiratory symptoms was increased in production workers, but this increase was not statistically significant. The duration of RCF exposure was related to pleuritic chest pain. Pulmonary function was decreased, and this decrease was significantly associated with duration of exposure. Chest radiographs revealed that the prevalence of pleural plaques overall in RCF production workers was 2.4 percent, while the prevalence in non-

production workers was 0 percent. Pleural plaques were seen in 18.2 percent of the workers with greater than 20 years' of RCF exposure in a production job. A recent study of asbestos workers demonstrated that those with pleural plaques had significantly higher death rates from lung cancer, mesothelioma, and asbestosis than those without pleural plaques. It did not appear, however, that the plaques became pleural mesothelioma, nor did lung cancer occur preferentially in the regions of the plaques (Selikoff et al., 1990, Doc. H-033e, Ex. 7-34).

Exposure data provided by the Thermal Insulation Manufacturers Association (TIMA) (1990, as cited in EPA, 1990/Doc. H-043) show airborne concentrations that range from 0.01 to 6.4 f/cc (average 0.62 f/cc) for manufacture, 0.02 to 56 f/cc (average <1 f/cc for most operations; 4-8 f/cc for vacuum-formed shapes manufacture and fabrication), and 0.01 to 24.72 f/cc (average 1.24 f/cc) for end use. Recent results of a study in progress at Johns Hopkins University directed by Morton Corn (Corn et al., 1990/Doc. H-043) show that workers in blanket fabrication are exposed to RCF concentrations in the range of 0.11 to 1.91 f/cc (mean 0.61 f/cc, maximum individual sample 8.38 f/cc) and in blanket installation in the range of 0.08 to 8.91 f/cc (mean 1.84 f/cc, maximum individual sample 22.9 f/cc). Those in bulk fiber fabrication are exposed to concentrations in the range of 0.05 to 1.83 f/cc (mean 0.57 f/cc, maximum individual sample 1.87 f/cc) and in bulk installation in the range 1.50 to 7.72 f/cc (mean 4.61 f/cc, maximum individual sample 12.14 f/cc). Those in vacuumformed products fabrication are exposed to concentrations in the range of 0.08 to 34.0 f/cc (mean 3.58 f/cc, maximum individual sample 143 f/cc) and in installation to concentrations in the range 2.03 to 8.58 f/cc (mean 5.31 f/cc, maximum individual sample 11.8 f/cc).

Animal Studies

In animal studies, exposure to RCF by several routes has been shown to cause nonmalignant respiratory effects. Alveolar lipoproteinosis and significant levels of pulmonary fibrosis developed in rats exposed for one year to 10 mg/m³ respirable ceramic fiber dust with 90 percent of the fibers having a diameter of <3 µm (Davis et al. 1984, as cited in IARC 1988/Doc. H-043, pp. 130 and 131). In another study, rats and hamsters exposed by inhalation to 0.5–10 mg/m³ RCF developed low levels of pulmonary fibrosis (Smith et al. 1987, as cited in IARC 1988/Doc. H-043, p. 131).

Hamsters, guinea pigs, and especially rats developed pulmonary fibrosis after a 3-month inhalation exposure to between 3000 and 40,000 f/cc of potassium octatintanate RCF, 3–15 μm in length (Lee et al. 1981; Lee and Reinhardt 1984, as cited in IARC 1988/Doc. H–043, p. 131). Gross et al. (1970b, as cited in IARC 1988/Doc. H–043, p. 131) found that intratracheal instillation of RCF in rats at a dose of 10.5 mg produced dust deposits that were surrounded by inflammatory cells.

Carcinogenicity

Human Studies

No epidemiological studies have been done to examine the risk of respiratory tract cancer or mesothelioma in workers exposed to RCF. However, as stated above, a very small percentage of RCF workers has a 20-year or longer time period since first exposure. Studies of asbestos workers have demonstrated that the latency period (the time between exposure to a substance and the onset of disease) for mesotheliomas can be as long as 45 years and is routinely between 20 and 40 years (Maltoni et al., 1991/Doc. H-033e, Ex. 124). Thus, it may be too early to be able to detect chronic diseases such as respiratory tract cancer and mesothelioma in RCF workers.

Animal Studies

Refractory ceramic fibers have also been shown to produce cancer in experimental animals treated by several routes of administration. Inhalation exposure to RCF has been shown to cause tumors in several studies. Lee et al. (1981, as cited in IARC 1988/Doc. H-043, p. 101) exposed rats and hamsters to 2900 f/cc potassium octatintanate fibers (19.1 percent <3 µm diameter) or 3100 f/cc amosite asbestos for 6 hours per day/5 days per week for 3 months. The animals were then observed for 21 months. At the end of the study, bronchoalveolar tumors were observed in 1/14 rats treated with potassium octatintanate, 3/11 treated with amosite asbestos, and 0/13 in untreated controls. One of the four potassium octatintanatetreated hamsters sacrificed at 18 months had a pleural mesothelioma. No other animals in any hamster treatment group had tumors.

Davis et al. (1984, as cited in IARC 1988/Doc. H-043, p. 101) exposed rats by inhalation to 10 mg/m³ respirable dust from fibrous ceramic aluminum silicate glass (90 percent of fibers $<3~\mu m$ length, $<0.3~\mu m$ diameter, aspect ratio >3:1) for 7 hours per day/5 days per week for 12 months. Malignant pulmonary

neoplasms were observed in 7/48 animals. There was also one benign adenoma. No pulmonary tumors were observed in 39 untreated controls. In another study, hamsters were exposed by nose-only inhalation to RCF dust at a concentration of 10.8 mg/m3 (35 percent respirable, geometric mean diameter 0.9 μm, geometric mean length 25 μm) for 6 hours per day/5 days per week for 2 years and observed for life. The exposure concentration was 200 f/cc, with 88 f/cc >10 µm in length and <1.0 um in diameter. A spindle cell mesothelioma of the lung developed in one of the 58 treated hamsters (Smith et al. 1987, as cited in IARC 1988/Doc. H-043, p. 102).

The Thermal Insulation Manufacturers Association (TIMA, 1990/Doc. H-043) has reported the results of a 2-year study in which hamsters and rats were exposed to RCF by nose-only inhalation at a concentration of 250 f/cc (>15 µm in length) for 6 hours per day, 5 days per week. A unique aerosol generation procedure was used in which large concentrations of unbroken fibers with little fiber dust could be produced. This procedure allowed for much greater respirability of fibers than had been achieved in previous fiber inhalation studies. Rats were treated with four types of RCF: Kaolin, zirconia, high purity, and "after service." Hamsters were treated with kaolin only. The study also included positive control groups treated with chrysotile asbestos (approximately 5000 f/cc, <5 µm in length) and negative controls treated with filtered air. At the 18-month final sacrifice, 35 percent (36/102) of the hamsters had pleural mesotheliomas. Fibrosis was also present. In contrast, the positive control chrysotile asbestosexposed hamsters had only fibrosis, with one hamster showing a nonmalignant pleural mesothelial growth. No lesions were seen in negative controls. By the 24-month interim sacrifice for the rats, pathological studies had shown two benign lung tumors, seven lung carcinomas, and three mesotheliomas in RCF-exposed animals. Chrysotile asbestos controls had a thymic adenoma and one lung carcinoma.

Mesotheliomas have also been produced by the intrapleural administration of RCF to rats. In one study, mesotheliomas developed in 3 of 31 rats that received a single intrapleural injection of 20 mg ceramic aluminum silicate fibers (0.5–1.0 μ m in diameter). One mesothelioma developed in a similar number of rats treated with nonfibrous aluminum oxide. Rats

treated with chrysotile asbestos had tumor incidences of 23/36 and 21/32 (Wagner et al. 1973, as cited in IARC 1988/Doc. H–043, p. 103). Stanton et al. (1981, as cited in IARC 1988/Doc. H–043, p. 104) treated rats with a single intrathoracic implantation of one of 13 different types of ceramic fibers. The incidences of pleural sarcomas were correlated with the number of fibers <0.25 μm in diameter and >8 μm in length and ranged from 1/45 to 21/29 in exposed animals.

exposed animals. The intraperitoneal (i.p.) administration of RCF has been shown to produce tumors in three studies with rats and one study with hamsters. In one study, 9 percent of rats injected with 25 mg fibrous ceramic aluminum silicate glass (90 percent fibers <3 µm in length and <0.3 µm in diameter) developed peritoneal tumors (one mesothelioma and two tumors similar to fibrosarcomas). Five percent of a group of untreated controls used for an inhalation study developed malignant tumors of the peritoneum or digestive system (Davis et al. 1984, as cited in IARC 1988/Doc. H-043, p. 105). In another study, tumors of the abdominal cavity were found in 32/47 and 12/54 rats that had received five i.p injections of two types of ceramic wool (median length, 8.3 µm; diameter 0.91 µm and median length 6.9 μm; diameter 1.1 μm). Injections of titanium dioxide caused tumors in 5/53 rats, and saline controls had a tumor incidence of 2/102. Positive control groups receiving actinolite or chrysotile had tumor incidences of 20/36 and 31/36 rats, respectively (Pott et al. 1987, as cited in IARC 1988/Doc. H-043, p. 105). Smith et al. (1987, as cited in IARC 1988/Doc. H-043, p. 105) treated rats and hamsters with a single i.p. injection of 25 mg RCF (geometric mean length, 25 µm; geometric mean diameter 0.9 µm; 83 percent fibers > 10 µm length and 86 percent < 2.0 µm diameter. Mesotheliomas were found in 19/23 of the treated rat group, in 2/15 and 5/21 of the treated hamster groups, and in none of the saline-treated or untreated controls.

Discussion

Based on what it viewed as the lack of reported adverse health effects in epidemiologic studies, the ACGIH (1986/Doc. H-020, Ex. 1-3) considered fibrous glass dust to be essentially a nuisance dust and applied a 10 mg/m³ TLV*-TWA.

In contrast, NIOSH (in 1977/Doc: H-043) concluded that "available data are sufficient to demonstrate that fibrous glass does not act like an inert or nuisance dust because it can produce fibrosis in animals and respiratory tract irritation in humans." Relying on several investigations that showed a lack of adverse effects among workers exposed to mean respirable fiber concentrations that were generally less than 5 to 6 f/cc, NIOSH recommended that exposures be limited to 3 f/cc for fibers >3.5 μm and >10 μm in length.

Recently, however, citing animal and epidemiological studies published since the NIOSH 1977 Criteria Document, NIOSH (1988, Doc. H-020, Ex. 8-47) has commented that these studies indicate the potential carcinogenicity of fibrous glass. NIOSH (1988/Doc. H-020, Ex. 8-47) commented, "It is likely * * * that even the 3 f/cc standard will not provide the degree of protection that OSHA believes is necessary for worker health and that reduction of the PEL to 0.2 f/cc * will be necessary to protect workers from the development of lung cancer." NIOSH (1988/Doc. H-020, Ex. 8-47, Table N6B) also believes that a full 6(b) rulemaking is needed for fibrous glass. NIOSH based its comments on the conclusion reached by Doll (1987/Doc. H-043, Ex. 1-11) to the effect that "* it is likely that man-made mineral fiber may have about the same carcinogenic potential as asbestos fibers of the same dimension, and that levels of 0.2 f/cc or less in industry are unlikely to produce a measurable risk after 20 years of exposure."

The Thermal Insulation Manufacturers Association (TIMA (1990b/Doc. H-043) has commented that it supports the application of NIOSH's REL of 3 f/cc for fibrous glass to all synthetic mineral fibers but does not believe that fibrous glass poses a human cancer hazard. Recently, however, TIMA (1991) has recommended that OSHA establish a PEL of 1 f/cc (8-hour TWA, NIOSH 7400B method) for fiber glass. According to TIMA, this recommendation is based on grounds of prudence and not significant risk. TIMA additionally recommended that fiber glass be classified as an irritant. Manville (1990/Doc. H-043), referring to fibrous glass, has stated that "Where industrial hygiene measurement is available on a continuous basis, a Manville workplace exposure guideline of 1 f/cc is suggested as a point above which respiratory protection should be used." Manville also believes that fibrous glass does not pose a human cancer hazard. The Carborundum Company (Doc. H-043) has a Recommended Exposure Guideline of 2.0 f/cc for worker exposure to RCF. Respiratory protection is recommended at and above this level. The refractory ceramic fiber subcommittee of TIMA has recently recommended an exposure

guideline of 1 f/cc, with workplace controls as appropriate (Given 1991/Doc. H-043). E.I. du Pont de Nemours and Company has an Acceptable Exposure Level of 0.5 f/cc for RCF and 2.0 for fibrous glass (personal communication from Frieda Fisher-

Tyler, 1991 The Building and Construction Trades Department of the American Federation of Labor-Congress of Industrial Organizations (A.F.L.-C.I.O., 1991) has recommended that OSHA establish a PEL of 1.0 f/cc as a TWA for the respirable fibers of fiber glass. The authors stated that the recommendation was consistent with the current state of their understanding of health risks, including the suggestive but not conclusive indication that these fibers may possess the ability to produce respiratory system cancer in exposed workers. A PEL of 0.1 f/cc was recommended for respirable refractory ceramic fibers based on the fact that inhalation studies with experimental animals have demonstrated that the carcinogenic potential of these fibers is similar to that of asbestos.

The International Agency for Research on Cancer (IARC 1988/Doc. H-043), in evaluating the carcinogenicity of fibrous glass and RCF, has concluded that glass wool and RCF are "possibly carcinogenic to humans (Group 2B)."

Current exposure limits (8-hour TWA) for all synthetic mineral fibers (unless specified) in several other countries that have recently studied the issue are as follows: Australia, 0.5 f/cc; Denmark, 2.0 f/cc; Great Britain, 1.0 f/cc; The Netherlands, 5.0 f/cc for glass wool and glass microfibers and 1.0 f/cc for refractory ceramic fibers; New Zealand, 1.0 f/cc; Norway, 1.0 f/cc; Poland, 2.0 f/cc, Sweden, 1.0 f/cc.

OSHA believes that a fiber-based standard is necessary. Industry representatives (Doc. H-020, Exs. 3-743, 8-56, 132, 175; Doc H-043) have argued strongly for a fiber-based standard, and NIOSH has recommended fiber-based counting procedures since 1977. TIMA points out that, for example, a 5 mg/m³ PEL for fibrous glass dust would permit a concentration of 4,000 f/cc for fibers 10 microns long and 0.25 microns in diameter (Doc. H-020, Ex. 3-743, p. 8).

In summary, OSHA has evaluated the available evidence on the health effects of fibrous glass, including refractory ceramic fibers. It has presented the strengths and weaknesses of the studies and discussed the possibility of confounding factors. Some of the human studies do not have contemporaneous exposure data; this means that, although current exposures are often quite low, it may be the case that earlier exposures

were higher. OSHA's discussion also presents the views of other organizations.

A statistically significant increase in mortality from nonmalignant respiratory disease has been observed in several studies of fibrous glass workers, including Bayliss et al. (1976) and Enterline et al. (1986, 1987). An ongoing morbidity study of RCF workers has demonstrated an increase in the prevalence of respiratory symptoms, pleuritic chest pain, and pleural plaques and a decrease in pulmonary function that was significantly associated with duration of exposures. In each of these studies, workers were exposed to fiber concentrations in the range of OSHA's proposed PEL.

OSHA believes, on the basis both of animal and human evidence, that a link between respiratory disease and exposure to fibrous glass exists. These respiratory effects constitute a material impairment of health. Based on this evidence, OSHA is proposing a 1 f/cc 8-hour TWA limit for the respirable fibers of fibrous glass, including refractory ceramic fibers. OSHA preliminarily concludes that this limit will substantially reduce the significant risk of nonmalignant respiratory disease that exists in the absence of a limit for workers in all sectors.

OSHA has presented the evidence of possible carcinogenicity of fibrous glass, including refractory ceramic fibers.

There is also a substantial body of ongoing research. At this time OSHA believes it is premature for the Agency to reach a final decision on an exposure limit based on carcinogenicity.

However, the proposed limit will also clearly increase the protection of workers from this effect as well.

OSHA is proposing the use of NIOSH counting method number 7400B and soliciting information on alternative counting methods.

OSHA believes this proposal is appropriate based on its review of the studies and their strengths and weaknesses, the recommendations of expert organizations, and the various ongoing studies that may provide important new data.

GRAIN DUST (OATS, WHEAT, AND BARLEY)

CAS: None; Chemical Formula: None H.S. No.: 1190

A decision by the Occupational Safety and Health Review Commission (Secretary of Labor v. Krause Milling Company, OSHRC Docket No. 78–2307, April 22, 1986) has held that there currently is no OSHA PEL for grain dust in the construction and maritime industries. There is also no limit in

agriculture. The ACGIH has a 10 mg/m³ TLV°-TWA for this substance. There is no NIOSH REL; however, NIOSH concurs (Ex 8-47, Table N1) with the limit OSHA is proposing in construction, maritime, and agriculture, which is a 10 mg/m³ 8-hour TWA PEL for grain dust generated from wheat, oats, and barley. Promulgation of this limit will make the PEL for grain dust consistent across all OSHA-regulated sectors.

Grain dust is a complex mixture of husk particles, cellulose hairs and spikes, starch granules, spores of fungi, insect debris, pollens, rat hair, and approximately 5 percent mineral particles. The mean particle size of the airborne dusts may be less than 5 μ m. Grain is exported, milled into flour, malted by the brewing industry, distributed as a feedstuff for animals or returned to the land as seed (Rom 1983, p. 221).

The acute grain dust toxicity data in animals are sparse. However, in-vitro studies have demonstrated that grain dust can stimulate lymphocyte proliferation and the production of interleukin-1 by rat alveolar macrophages (Ye, Lewis, Sorenson, and Olenchock 1988). Another study (Alam, Lewis, and Olenchock 1988) has shown that grain dust can stimulate lymphocytes, mast cells, and basophils, i.e., those cells involved in producing inflammatory responses, in cultured guinea pig spleen and lung tissue.

In humans, exposure to grain dust causes both acute and chronic effects. The adverse effects of inhaling grain dust have been known for at least twoand-one-half centuries, dating back to Rammazini who, in 1713, described the respiratory hazards associated with exposure to cereal grain dust. More recently, several epidemiological studies conducted over the past few decades have demonstrated that exposure to grain dust causes "grain fever." wheezing, chest tightness, productive cough, eye and nasal irritation, and symptoms of chronic respiratory disease. Grain dust may also induce asthmatic reactions via an allergic mechanism, particularly in individuals who are predisposed to developing allergies (i.e., atopic individuals).

Epidemiological studies have shown that as many as 25 percent of grain elevator workers experience grain fever (Broder et al. 1979; Chan-Yeung et al. 1980; doPico et al. 1980; Tse et al. 1973). Increased rates of cough, shortness of breath, and wheezing were reported in 23 percent of English grain farmers (N=65) (Darke et al. 1976). Seventy-six percent of dock workers handling grain

were found to have chest tightness or grain fever (Lockcroft et al. 1983).

The basis for OSHA's proposed 10mg/m3 limit in the construction, maritime, and agriculture sectors is a NIOSH-sponsored study of grain workers by Rankin et al. (Study of the Prevalence of Chronic, Non-Specific Lung Disease and Related Health Problems in the Grain Handling Industry, DHHS (NIOSH) Pub. No. 86-117, 1986). This study evaluated the health status of 310 grain handlers in Wisconsin and Minnesota. The grain handlers were selected from employees at eight elevator companies, from state grain inspection agencies, and from longshoring companies. Health status was determined by questionnaire and by physical examination, which included an assessment of pulmonary function, immunologic evaluation, blood and urine chemistries, and chest roentgenograms. The comparison group that served as controls consisted of 239 city workers who spent the majority of their workdays outside.

From the questionnaires, Rankin et al. (1986) found that the grain handlers had a higher prevalence of respiratory symptoms than did the city workers. The prevalence of respiratory symptoms was highly significant (Rankin et al. 1986, Table 13), and was independent of smoking status. The symptoms reported by grain handlers represented both acute and chronic airways reactions (occupational asthma and chronic bronchitis). Wheezing and/or chest tightness generally started within two hours of beginning the work shift. Episodes of grain fever occurred infrequently; this was attributed by the workers to improved working conditions over the previous three years. However, acute recurrent conjunctivitis and rhinitis were reported to occur among

most grain workers. Lung function tests showed that exposure to grain dust had a highly significant adverse effect on pulmonary function (Rankin et al. 1986, Table 30). There was, however, no correlation between reduced pulmonary function and job category, length of employment, or place of work. The lung function decrement observed among grain handlers was not related to smoking history alone; grain handlers who were smokers or ex-smokers showed significant declines in pulmonary function when compared to city workers who were smokers or ex-smokers.

Grain workers who reported symptoms had lower values of ventilatory function than did workers without symptoms. The prevalence of chronic bronchitis symptoms with measured airway obstruction was higher in grain workers than in controls, regardless of smoking history. Chronic bronchitis with airway obstruction was also related to length of employment. Rankin et al. (1986) concluded that these findings "suggest that chronic grain dust exposure may result in chronic obstructive pulmonary disease" (p. 26).

Rankin et al.'s (1986) study also included a work-shift study in which 248 grain workers and 192 city workers were sampled for grain dust exposure during a work shift. Symptoms occurring during the shift were recorded and pulmonary function readings were taken before and after the shift. Only 14 percent of grain workers were exposed to an 8-hour TWA level exceeding 5 mg/m3 total grain dust; 7 percent were exposed above 10 mg/m³. Rankin et al. (1986) reported that grain workers showed a significant excess of cough and expectoration during work shifts in which dust concentrations were below 5 mg/m3. At dust levels between 10 and 15 mg/m3, there was a significantly increased prevalence of wheezing and dyspra during the shift among grain work as compared with controls (Rankin et al. 1986, Table II-158). Workers with pre-existing airway obstruction experienced significant preto post-shift declines in ventilatory function at dust levels below 10-mg/m3. However, the changes observed in preto post-shift pulmonary function did not correlate with the presence of symptoms during the shift.

Rankin et al. (1986) also conducted a short-term (three-year) follow-up study of lung function among grain workers. Their results showed no greater declines in FEV or FVC over the three-year period than could be accounted for by age alone. However, there was a significant decline in other measures of lung function (MMF, V_{max50}, V_{max75}) among both smoking and nonsmoking grain workers. The authors concluded that, although a grain-dust-related decline in these measures was observed, the long-term effects of smoking on lung function were probably greater than those caused by grain dust

those caused by grain dust. The findings of the Rankin et al. (1986) study are consistent with those of other recent published studies (NIOSH 1988; Tse 1990; Hurst and Dosman 1990; Richerson 1990; Revsbeck and Andersen 1989) of grain workers employed in establishments in various sectors. For example, Dr. Roy Buchan, Chief of the Occupational Health and Safety Section, College of Veterinary Medicine and Biomedical Sciences at Colorado State University, performed a study of the general health of 31 grain handlers (submitted as part of Ex. 3-751). A total of 204 personal TWA dust samples were

taken, of which only six exceeded 10 mg/m3. Dr. Buchan found that neither age of facility, smoking history, nor past exposure to grain dust had any significant effect on symptom responses. There was a statistically significant association between grain dust exposure levels and symptom responses. The reported symptoms included nasal and throat irritation, chest discomfort, and phlegm production. Dr. Buchan concluded that, "although the association was mathematically weak but statistically significant, it would rationally be expected that symptom severity would become more pronounced as dust concentrations increase, since dust exposures in this investigation were surprisingly low (mean=0.7 mg/m3 TWA)." In a larger study of 390 Canadian grain workers, Cotton, Graham, Li et al. (1983, submitted as part of Ex. 3-751) also reported a significant excess incidence of respiratory symptoms among grain workers despite total dust concentrations generally below 10 mg/

Although these studies show a pattern of increased prevalence of respiratory symptoms among grain handlers exposed below 10 mg/m3, the association between low-level exposure to grain dust and the development of chronic pulmonary disease remains open to interpretation. Several studies, including those of Rankin et al. (1986). Chan-Yeung, Giclas, and Henson (1980/ Ex. 1-474), and Broder, Corey, Davies et al. (1985, as cited in Ex. 3-751) have generally not found decrements in pulmonary function associated with long-term exposure to grain dust. In addition, chest roentgenograms have found no evidence of lung scarring or fibrosis (Rankin et al. 1986) among grain handlers. However, symptoms of chronic bronchitis have frequently been noted among grain handlers, including those who have never smoked (Rankin et al. 1986; Cotton, Graham, Li et al. 1983). According to Cotton et al. (1983, as cited in Ex. 3-751, p. 139), "The significance of the increase in chronic bronchitis and cough in workers and wheezing in nonsmoking workers in terms of eventual respiratory disability remains uncertain but the nuisance and discomfort of these symptoms for workers must also be considered."

In the prior rulemaking in general industry, some commenters (Exs. 8–55, 180, and 185) took the position that grain dust is a nuisance dust. OSHA does not concur with this view. In the studies described above, as well as in others in the record, grain workers in all regulated sectors have consistently reported an

excess prevalence of respiratory symptoms, including chronic bronchitis, at low levels of exposure to grain dust. OSHA believes that these symptoms, even in the absence of definitive evidence of irreversible lung damage, constitute material impairment of health and interfere with the well-being of workers. In the prior rulemaking, this was attested to at the informal hearing by Deborah Berkowitz, Director of Safety and Health for the Food and Allied Trades Department, AFL-CIO:

I want to make it clear that study after study documents a very real acute hazard to grain workers. Living with chronic bronchitis is not a hazard that should go unchecked. In fact, study after study point to the possibility of very real long-term damage from chronic cumulative effects of exposure to grain dust. But even without the possibility of long-term disability, acute hazards clearly pose significant risk[s] to workers (Tr. pp. 6–306 to 6–307).

Thus OSHA preliminarily concludes that employees in construction, maritime, and agriculture are at significant risk of developing respiratory symptoms, including chronic bronchitis, as a result of their exposure to grain dust. It is clear that such symptoms occur at grain dust levels exceeding OSHA's current limit in construction and maritime for dusts and particulates (15 mg/m³ TWA). Increases in respiratory symptoms have also been reported to occur among grain workers exposed generally to concentrations of less than 10 mg/m³, although symptoms are diminished in intensity at these lower levels. At this time, it is difficult to identify the precise threshold at which adverse respiratory effects are likely to

Based on this evidence in workers, OSHA is proposing an 8-hour TWA limit of 10 mg/m3 in construction, maritime, and agricultural operations for grain dust, measured as total dust. Grain dusts other than oats, wheat, and barley will continue to be covered under OSHA's generic "particulates not otherwise regulated" PEL of 15 mg/m3 (total particulate) and 5 mg/m3 (respirable fraction). Promulgation of this limit for grain dust will make OSHA's PEL for this substance consistent across all regulated sectors. GRAPHITE, NATURAL CAS: 7782-42-5; Chemical Formula: None

H.S. No. 1191

The current OSHA limit for natural graphite (total dust) in the construction and maritime industries is 15 million particles per cubic foot (mppcf), which is equivalent to 2.5 mg/m³ as respirable dust (assuming that respirable mass is one-half total particle mass). There is no

limit for natural graphite in agriculture. The ACGIH has an 8-hour TLV*-TWA of 2.5 mg/m³ for graphite (respirable dust). NIOSH has no REL for this substance. In construction and maritime, OSHA is retaining the 8-hour TWA PEL of 2.5 mg/m³ for respirable natural graphite dust containing less than 1 percent quartz but changing the units in which the limit is expressed from mppcf to mg/m³. OSHA is also proposing an 8-hour TWA PEL of 2.5 mg/m³ in agriculture. NIOSH concurred (Ex. 8-47, Table N1) with this limit when OSHA recently established it in general industry.

Natural graphite, also called plumbago and mineral carbon, is a relatively soft, greasy-feeling, steel gray to black solid with a metallic sheen. In nature, graphite is usually associated with impurities, such as silica, mica, granite, etc. Graphite is used in "lead" pencils, refractory crucibles, foundry facings, stove polishes, pigments, lubricants, cements, matches, and explosives (Hawley's 1987, p. 576; Merck 1983, p. 652; ACGIH 1986, p. 290(89)).

There are few data on the toxicity of graphite in experimental animals. Administered to rats by intratracheal injection, graphite with a "low ash content" caused fibrosis of the lung; however, the amount of silica or other impurities in the graphite was not determined (Ray, King, and Harrison 1951/Ex. 1-46). A recent study (Thomson, Bergmann, Burnett, Carpin, and Crouse 1988) shows that exposure to natural graphite, which contains silicate minerals, and to synthetic graphite, which contains less than 1 percent silica, both elicit physiologic changes in the lungs of rats exposed to 100 mg/m³ of each substance for 4 hours/day for 4 days

Early reports established that graphite deposited in the lungs of occupationally exposed workers caused pneumoconiosis (Koopman 1924/Ex. 1-131). Subsequent research described the condition produced by exposure to graphite as anthracosilicosis, a pulmonary condition similar to that seen in coal miners, based on radiographic and histologic examinations in exposed individuals (Harding and Oliver 1949/ Ex. 1-71). Radiologic changes were also observed among graphite mine and production workers exposed to graphite containing from 3.6 to 10 percent silica (Pendergrass, Vorwald, Mishkin et al. 1967/Ex. 1-77). A recent study of the incidence of graphite-induced pneumoconiosis in Sri Lankan graphite miners shows that the incidence was substantially lower in workers from a mine equipped with dust controls (3.4) percent) compared with that in workers

from a mine without such controls (18.3 percent) (Uragoda 1989). A 1983 review article (Hanoa 1983) concludes that, because information reported in the literature is often unclear both about the composition of the natural graphite and the extent of occupational exposure, it is difficult to distinguish the extent of pure graphite's contribution to the development of graphite pneumoconiosis. The author concluded, on the basis of a review of 18 epidemiologic studies of graphiteexposed workers, that the possibility that pure graphite causes pneumoconiosis cannot be ruled out. although most of these studies suggest that pneumoconiosis is a mixed-dust reaction (Hanoa 1983).

OSHA is proposing to revise its former limit of 15 mppcf to the equivalent limit of 2.5 mg/m3 for the respirable fraction of graphite containing less than 1 percent quartz for the construction and maritime industries and to extend this limit to agriculture. In construction and maritime, this change represents a change only in the units used to express or measure the limit, not a change in the value of the limit. OSHA is revising its limit to simplify the monitoring of employee exposures because the use of impingers and microscopic analyses are not required to measure exposures that are expressed in mg/m³ rather than in mppcf. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

INDIUM AND COMPOUNDS CAS: 7440–74–6; Chemical Formula: In H.S. No. 1213

OSHA's exposure limit for indium and compounds in the construction and maritime industries is 0.1 mg/m3 as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV®-TWA of 0.1 mg/m3 for these substances; NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. The Agency is retaining its limit for construction and maritime operations and is proposing to extend this 0.1 mg/m3 8-hour TWA limit to agricultural operations. Promulgation of this limit will make the PEL for this substance consistent across all OSHAregulated sectors.

Indium metal is silver-white, shiny, and ductile. Indium is used in bearings for automobiles and aircraft, in electronic devices, low melting alloys, and reactor control rods. Indium compounds are not widely used; however, indium antimonide, indium arsenide, and indium phosphide are used in semiconductor devices.

There are few acute toxicity data for indium and its compounds. The lowest lethal dose of indium in mice by subcutaneous injection is 10 mg/kg (RTECS 1990). The oral LD50 for indium in rats is 4200 mg/kg (ITI 1986, p. 620). Rats inhaling the sesquioxide form of indium at airborne concentrations ranging from 24 to 97 mg/m3 daily for a total of 224 hours developed widespread alveolar edema; these histologic lesions did not change over a 12-week postexposure period (Leach, Scott, Armstrong et al. 1961). Animals exposed to indium show reduced alveolar clearance and may develop chronic respiratory insufficiency and recurrent acute pneumonitis before death (Jones 1960). Animals chronically poisoned with indium show weight loss, blood changes, signs of pulmonary edema, and, at autopsy, damage to the liver and kidneys (McCord, Meeks, Harrold, and Henssner 1942). Several studies have shown indium to be teratogenic in experimental animals (Farm 1972; Cralley and Cralley 1985).

In humans, exposure to indium and its compounds causes eye, mucous membrane, and skin irritation (Hazardous Substance Fact Sheet 1986). No other information on indium's toxicity in humans is available.

Based on this evidence in humans and animals, OSHA believes that exposed workers in construction, maritime, and agriculture are at significant risk of developing sensory irritation and chronic lung function impairment, both adverse health effects associated with exposure to indium. To substantially reduce the risk of these material health impairments, the Agency is retaining its 8-hour TWA limit of 0.1 mg/m3 for indium and its compounds in the construction and maritime industries and is proposing to extend this limit to agriculture. Promulgation of this limit will make OSHA's PEL for this substance consistent across all OSHAregulated sectors.

IRON OXIDE (DUST AND FUME) CAS: 1309-37-1; Chemical Formula: Fe₂O₃

H.S. No. 1215

In the construction and maritime industries, OSHA has an 8-hour TWA limit of 10 mg/m³ for iron oxide fume. There is no limit in agriculture. The ACGIH has a TLV®-TWA of 5 mg/m³, measured as iron, total particulate. NIOSH has no REL for this substance. OSHA is retaining its 8-hour TWA PEL of 10 mg/m³ for the construction and maritime industries and is proposing to extend this limit to agriculture. NIOSH concurred (Ex. 8-47, Table N1) that this limit was appropriate when OSHA

recently established it in general industry.

The fume of iron oxide is red-brown in color. Iron oxide is used as a pigment for rubber, paints, paper, linoleum, ceramics, and glass; in paint for iron work and ship hulls; as a polishing agent for glass, precious metals, and diamonds; as a catalyst; in colloidal solutions; and as a stain for solutions; and as a stain for

polysaccharides (Merck 1983, p. 579). The intraperitoneal LD₅₀s in rats and mice are 5500 mg/kg and 5400 mg/kg. respectively (RTECS 1990). Animals exposed to iron oxide or to iron oxide mixed with less than 5 percent silica by inhalation or by intratracheal injection did not develop pulmonary fibrosis (Naeslund 1940/Ex. 1-650; Harding, Grout, Durkan et al. 1950, as cited in ACGIH 1986/Ex. 1-3, p. 325). A recent study (Wright, Harrison, Wiggs, and Churg 1988) confirms these findings; iron oxide (10 mg) administered to rats by intratracheal injection had not caused any morphological or pulmonary function changes in these animals 30 days later. Hamsters injected once per week for 15 weeks by the intratracheal route of administration with 3 mg ferric oxide dust survived for 1 to 2 years and did not develop tumors (Saffiotti et al. 1968). In an evaluation of iron oxide's carcinogenic potential, the International Agency for Research on Cancer concluded that the evidence for the carcinogenicity of ferric oxide suggested that this substance was not carcinogenic in animals (IARC 1987, Suppl. 7, p. 217).

The evidence of iron oxide's respiratory toxicity in humans is conflicting. Drinker, Warren, and Page (1935/Ex. 1-315) concluded that exposures to iron oxide fume should be maintained below 10 mg/m3, and a U.S. Department of Labor study (1941, as cited in ACGIH 1986/Ex. 1-3, p. 325) found that exposures below 30 mg/m3 were without adverse effect. There are several studies, on the other hand, that report chest X-ray abnormalities in iron oxide-exposed miners, welders, silver polishers, electrolytic iron oxide workers, foundry workers, and boiler scalers (Doig and McLaughlin 1936/Ex. 1-626; Stewart and Faulds 1934/Ex. 1-764; Doig and McLaughlin 1948/Ex. 1-627; McLaughlin, Grout, Barrie, and Harding 1945/Ex. 1-642; Davidson 1951, as cited in McLaughlin 1951/Ex. 1-727; Pendergrass and Leopold 1945/Ex. 1-653; Dunner and Hermon 1944/Ex. 1-731). Some of these workers developed disabling pneumoconiosis; however, the exposures of many of these workers were mixed and in some cases included exposure to varying amounts of silica.

McLaughlin (1951/Ex. 1-727), whose opinion on the subject is widely

accepted, believes that the presence of iron oxide dust or fume in the lung causes a pigmentation (termed siderosis) that is responsible for the changes seen in exposed individuals' chest X-rays. Siderosis is believed not to progress to fibrosis, and 6 to 10 years of exposure to about 15 mg/m3 iron oxide dust is required before this condition develops (Fawcett 1943/Ex. 1-736; Fleischer, Nelson, and Drinker 1945/Ex. 1-1051; Hamlin and Weber 1950/Ex. 1-698). In a group of 25 welders exposed primarily to iron oxide fume at 0.65 to 47 mg/m3 concentrations for 3 to 32 years, eight had shadows on their X-rays typical of siderosis, but none of these workers had pulmonary function deficits (Kleinfeld, Messite, Kooyman, and Shapiro 1969).

Dr. Stuart M. Brooks (NIOSH 1986b, p. 425) notes that "[m]ore sophisticated physiologic testing, including measurement of the lung's mechanical properties, is required to better document lung function changes that may occur following inhalation of ironcontaining dusts. In vitro studies or animal experimentation might be helpful in determining dose-response relationships, understanding lung clearance mechanisms for iron, and elucidating any fibrogenic properties of various ferrous compounds."

Some studies have shown that workers with exposures to iron oxide and such other substances as silica, radon gas, diesel exhaust, corn oils, and the thermal decomposition products of synthetic resins (Faulds 1957/Ex. 1-635; Dreyfus 1936/Ex. 1-897; Bidstrup 1959/ Ex. 1-1030; Boyd, Doll, Faulds, and Leiper 1970/Ex. 1-716; Braun, Guillerm, Pierson, and Sadoul 1960/Ex. 1-1141; Monlibert and Roubille 1960/Ex. 1-647; Jorgensen 1973/Ex. 1-1023; Muller and Erhardt 1956/Ex. 1-648; Koskela, Hernberg, Karava et al. 1976/Ex. 1-744; Gibson, Martin, and Lockington 1977/ Ex. 1-1053) have a greater risk of developing lung cancer. However, OSHA agrees with the International Agency for Research on Cancer that "Some studies of metal workers exposed to ferric oxide dusts have shown an increased incidence of lung cancer, but the influence of factors in the workplace other than ferric oxide, i.e., soots, silica, and asbestos in foundry work, cannot be discounted. In other studies of metal and chemical workers exposed to ferric oxide, the incidence of lung cancer has generally not been increased" (IARC 1987, Suppl. 7, p. 217). A recent review of the epidemiological and experimental evidence for the carcinogenicity of iron oxide reaches the same conclusion (Lauwerys 1989) but notes that ironcontaining dust may act as a

cocarcinogen.

Based on this evidence, OSHA is retaining the Agency's PEL for iron oxide dust and fume of 10 mg/m3, measured as total particulate, in construction and maritime, and is proposing this limit in agriculture. The Agency preliminarily concludes, based on the evidence currently available, that this limit will protect workers in these sectors from developing siderosis, a benign pneumoconiosis that occurs after many years of exposure to iron oxide dust or fume. OSHA considers this condition a material health impairment and believes that this PEL is necessary to reduce the risk of this effect. In addition, promulgation of this limit will make OSHA's PEL for iron oxide consistent across all regulated sectors. METHYLENE BIS-(4-

CYCLOHEXYLISOCYANATE) CAS: 5124-30-1; Chemical Formula: C15H22N2O2

H.S. No. 1272

OSHA has no limit for methylene bis (4-cyclohexylisocyanate) in the construction, maritime, or agriculture industries. The ACGIH has a TLV® ceiling limit of 0.01 ppm for this alicyclic diisocyanate compound. NIOSH has no REL for this substance, OSHA is proposing a ceiling limit of 0.01 ppm for this substance in construction, maritime, and agricultural operations. NIOSH (Ex. 8-47, Table N1) concurred with this limit when the Agency recently established it in general industry.

Methylene bis (4cyclohexylisocyanate) is a liquid belonging to the family of alicyclic diisocyanates. It is used primarily to produce urethane products (ACGIH

1986, p. 392.5(86)).

Methylene bis (4cyclohexylisocyanate) is a skin, eye, and lung irritant. The oral LDso in rats is 9.9 g/kg (RTECS 1990). By inhalation, exposure to a 20 ppm concentration for 5 hours caused death to 50 percent of exposed rats (RTECS 1990). A 5-percent solution applied to the skin of guinea pigs produced strong erythema and edema, and rabbits treated with 0.1 mg showed severe skin reactions (Younger Laboratories 1965, as cited in ACGIH 1986/Ex. 1-3, p. 392). Rats inhaling a lethal concentration of 20 ppm for five hours exhibited marked respiratory irritation, tremors, and convulsions during exposure, and their lungs revealed severe congestion and edema after death (E.I. du Pont de Nemours and Co. Inc. 1976, as cited in ACGIH 1986/ Ex. 1-3, p. 392). Repeated inhalation exposure to 0.4 ppm produced initial weight loss in rats; exposure to 1.2 ppm

caused respiratory irritation and decreased growth (E.I. du Pont de Nemours and Co. Inc. 1978, as cited in ACGIH 1986/Ex. 1-3, p. 392). Guinea pigs exposed to 0.12 ppm and mice exposed to 0.65 ppm did not exhibit dermal sensitivity (Stadler and Karol 1984/Ex. 1-612). Unlike toluene diisocyanate, which is a sensory irritant, methylene bis (4-cyclohexylisocyanate) depresses respiration by producing pulmonary irritation; for example, an exposed mouse showed a 50-percent decrease in respiration rate, along with lung irritation, when exposed to 3.7 ppm of this substance (Weyel and Schaffer 1985/Ex. 1-581).

Methylene bis (4cyclohexylisocyanate) causes sensory irritation of the eyes, nose, and throat, and contact with the eyes can lead to permanent damage (Hazardous Substance Fact Sheet 1986). Workers exposed to this compound have developed skin sensitization, but pulmonary sensitization is less common (Emmett 1976/Ex. 1-552; Israeli, Smirnov, and Sculsky et al. 1981/Ex. 1-

OSHA is proposing a ceiling limit of 0.01 ppm for methylene bis (4cyclohexylisocyanate) in the construction, maritime, and agriculture industries. The Agency believes that this limit will protect workers in these sectors against the significant risk of eye, skin, and pulmonary irritation potentially associated with occupational exposures to this substance at the levels permitted by the absence of an OSHA limit. The Agency considers these irritant effects caused by exposure to methylene bis (4-cyclohexylisocyanate) to be material impairments of health and believes that the proposed limit will substantially reduce the risk of these impairments. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

MICA

CAS: 12001-26-2; Chemical Formula: K2AL(Al2Si6O20)(OH)4 H.S. No. 1276

In the construction and maritime industries, OSHA has an 8-hour TWA PEL of 20 mppcf for mica containing less than 1 percent crystalline silica; this limit is equivalent to a PEL of 3 mg/m3 when expressed in mg/m3. There is no PEL in agriculture. The ACGIH has a TLV*-TWA of 3 mg/m3 for the respirable dust of mica containing less than 1 percent quartz. NIOSH has no REL for this substance. In construction, maritime, and agriculture, OSHA is proposing an 8-hour TWA limit of 3 mg/ m3 for the respirable dust of mica

containing less than 1 percent quartz. NIOSH concurred (Ex. 8-47, Table N1) with this limit when the Agency recently established it in general industry.

Mica is a colorless, odorless, nonflammable, nonfibrous, waterinsoluble silicate occurring in plate form and containing less than 1 percent quartz; it includes nine different species. Mica is used in electrical equipment, vacuum tubes, incandescent lamps, dusting agents, lubricants, in windows of high-temperature equipment, exterior paints, cosmetics, roofing, rubber, wallpaper and wall board joint cement, and in oil-well drilling muds (Hawley's 1987, p. 785).

Early animal experiments in guinea pigs involving the intraperitoneal injection of mica showed that this substance was inert by this route of administration (Miller and Sayres 1941). Two workers exposed to muscovite (mica) dust at unspecified concentrations developed hepatic and pulmonary granulomas (Pimenthel and Menezes 1978). Five of six workers exposed to mica dust at concentrations greater than 25 mppcf (about 4 mg/m3) for more than 10 years developed pneumoconiosis (Dreessen et al. 1940). The symptoms most frequently reported by these workers were chronic cough, dyspnea, weakness, and weight loss (Dreessen et al. 1940). Some authors (Parkes 1974) question whether mica alone (without silica) can cause pneumoconiosis. However, Vestal et al. (1943) determined that more than 10 percent of workers exposed to pure mica had developed this condition.

OSHA believes that the evidence strongly suggests that mica is a pneumoconiotic agent and therefore that workers exposed to this substance in their work are at significant risk of experiencing this material health impairment. Accordingly, OSHA is proposing an 8-hour TWA limit of 3 mg/ m³ for respirable mica dust containing less than 1 percent quartz in the agriculture industry and is retaining this limit in construction and maritime. This limit corresponds to the existing 20mppcf PEL and is in keeping with the Agency's decision to delete mppcf values in favor of respirable dust values expressed in mg/m3. The Agency has decided to express this and other similar limits as mg/ms to facilitate employee exposure monitoring. Promulgation of this limit also will make OSHA's PEL for this substance consistent across all regulated sectors.

MINERAL WOOL FIBER CAS: None. Chemical Formula: None H.S. No. 1277

OSHA currently has no limit in any industry sector specifically for mineral wool fiber, but this substance is covered by the Agency's 15-mg/m³ 8-hour TWA limit for all inert dusts and particulates. The ACGIH (1986/Doc. H-020, Ex. 1-3, p. 414) recommends an 8-hour TWA limit of 10 mg/m³ for mineral wool fiber as total dust containing less than 1 percent quartz. OSHA is proposing an 8-hour TWA PEL of 1 fiber per cubic centimeter (f/cc) of air for the respirable fibers of mineral wool in general industry, construction, maritime, and agriculture.

There are two types of mineral wool, known as rockwool and slagwool. These fibers are produced by blowing, centrifuging, or drawing molten rock or slag. Rockwool is typically made from igneous rocks such as diabase, basalt, and olivine, and carbonate rocks containing 40–60% calcium and magnesium carbonates. Slagwool is made from the fused agglomerate byproducts of certain metal smelting

processes.

In animal studies, exposure to mineral wool fibers by the inhalation route has been shown to cause respiratory effects. Focal fibrosis was observed at 4 months post-exposure in rats exposed to 10 mg/ ms of rockwool or chrysotile asbestos for 50 weeks (Johnson and Wagner 1980, as cited in Vu 1988/Doc. H-043, p. 86). The asbestos-exposed rats were affected to a greater degree. Unexposed rats did not develop fibrosis. Rats and hamsters exposed by inhalation to rockwool (Wagner et al. 1984, as cited in Vu 1988/Doc. H-043, p.86; Le Bouffant et al. 1987, as cited in IARC 1988/Doc. H-043, p. 131) or slagwool (Smith et al. 1987, as cited in IARC 1988/Doc. H-043, p. 131) at concentrations of 0.5-10 mg/ m3 developed low levels of pulmonary

Several epidemiological studies of workers exposed to mineral wool have shown that these workers have an excess risk of nonmalignant respiratory disease (NMRD). Weill et al. (1983, as cited in IARC 1988/Doc. H-043, p. 135; 1984, as cited in IARC 1988/Doc. H-043, p. 135) and Hill et al. (1984, as cited in IARC 1988/Doc. H-043, p. 135) have reported the occurrence of lung opacities in a limited number of workers in the mineral wool or synthetic mineral fibers (SMF) manufacturing industry. An increased frequency of bronchitis that was directly related to duration of exposure to SMF has been observed in a group of 135,000 construction workers (Engholm and von Schmalensee 1982/ Doc. H-043). The calculated standard rate ratios in each smoking category indicated a positive association between

bronchitis and exposure to SMF. Among nonsmokers, 77 percent of cases of bronchitis in workers with long exposure were attributable to the exposure. The corresponding fraction in present smokers was 28 percent. The authors concluded that there is a clear association between bronchitis and handling of SMF in the construction industry. Enterline and co-workers (Enterline et al. 1983/Doc. H-043, Ex.1-17; 1986/Doc. H-043, Ex. 1-1; 1987, Doc. H-043; Enterline 1987, as cited in Vu 1988/Doc. H-043, p. 93) studied 16,661 white male workers in 17 synthetic mineral fibers plants, with 1 or more years of experience in production or maintenance during the period 1945-1963. This cohort consisted of 14,815 workers in 11 fibrous glass plants and 1846 workers in 6 mineral wool plants. The SMR for all synthetic mineral fiber workers for NMRD (excluding influenza and pneumonia) was statistically significantly increased. The SMR was 132.3 (p < 0.01) when U.S. rates were used for comparison and 134.1 (p < 0.01) when local rates were used. The authors found a nonstatistically significant excess mortality from NMRD among mineral wool workers in the 6 plants studied when their rates were compared with local or national rates. In one plant, however, there was a statistically significant excess risk of NMRD for those workers who had first been exposed 20 or more years ago (SMR 219.9, p < 0.05) and for plant workers overall (SMR 221.0, p < 0.05) but not for those who had first been exposed less than 20 years ago. The average exposure concentration was 0.353 f/cc for all plants and 0.427 f/cc for the plant with the significant excess risk. Marsh et al. (1990/Doc. H-043) completed a followup to 1985 of the Enterline et al. cohort. The SMR for NMRD (excluding influenza and pneumonia) for all SMF workers was 129.4 (p < 0.01) when local rates were used for comparison; U.S. rates were not used for comparison. In one mineral wool plant (a different plant than that observed to have increased risk in the earlier study), there was a significantly increased risk of NMRD for those workers who had been exposed 20 or more years ago (SMR 189.0, p < 0.05).

Two major epidemiological studies conducted in workers exposed to mineral wool have shown that these workers have an excess risk of lung and other respiratory tract cancers. Enterline et al. (1987/Doc. H–043) examined the 1946–1982 mortality experience of 16,661 SMF workers employed one year or more during 1945–1963 at one or more of 17 U.S. manufacturing plants. Compared with local death rates, there was a

statistically significant excess in all malignant neoplasms and in the incidence of lung cancer 20 years or more after first employment. For respiratory cancer, this excess was greatest for mineral wool workers and small-diameter-fiber workers. In the subcohort of 1846 white male workers from six U.S. slagwool or rock-/ slagwool plants, the SMRs for respiratory cancer were 148 (based on national comparison) and 134 (local) (p <0.01 and p <0.05). The SMRs for workers with fewer than 20 years since first exposure were 156 (national) and 143 (local) and 146 (national) (p < 0.05) and 131 (local) for those with 20 years or more since first exposure. Workers employed most recently had the highest SMRs. For example, in workers who started work during 1950-1959, the SMRs were 216 (national) and 198 (local) (both p < 0.01). A smoking survey showed that SMF workers have cigarette-smoking habits similar to those of all U.S. white males. When the effects of smoking were controlled for, the relationship between fiber exposure and respiratory cancer continued to be statistically significant for mineral wool workers. Mean fiber exposure levels in the mineral wool plants were estimated to range from 0.195 to 0.427 f/cc. The highest individual average fiber exposure level was estimated to be 1.4 f/cc. When the study was updated to include a follow-up to 1985, a statistically significant increase in mortality for respiratory cancer was still evident (Marsh et al. 1990/Doc. H-043). Simonato et al. (1987/Doc. H-043) studied 24,609 workers producing rock/ slagwool, glasswool, or glass filament in 13 European factories in seven countries. Mineral wool workers numbered 10,115 and worked in seven factories in four countries. The study had an observation period of 30 years from first employment. A slight excess of mortality was seen in these workers overall, and this increase was primarily due to an overall excess rate of cancer. The excess mortality due to lung cancer was significant, particularly in rock/slag wool workers employed during the early production years. The highest SMRs (250 national; 303 local) were seen in the group that had been followed for more than 20 years. For all seven of the mineral wool workers, lung cancer risk increased with time since first exposure. In addition, there was a statistically significant excess in the incidence of cancers of the buccal cavity and pharynx (SIR, 181) (Simonato et al. 1986/ Doc. H-043, Ex. 1-4) and a statistically significant increasing trend in bladder cancer mortality with time since first

exposure (Simonato et al. 1987/Doc. H-043). The combined occupational group mean fiber concentrations in these plants, on the basis of measurements taken in 1977-1980, ranged from 0.01 to 0.67 f/cc. The highest concentrations were observed in certain specialist secondary production groups. The mean fiber concentrations in the main production and secondary production groups ranged from 0.05 to 0.12. The average plant median for fiber length ranged from 10-20 µm. The median diameters ranged from 1.2 to 2 µm (Cherrie et al. 1986/Doc. H-043, Ex. 1-4). Robinson and co-workers (1982, as cited in IARC 1988/Doc. H-043, p. 145) reported an increase in mortality from cancer of the digestive tract in a U.S. mineral wool plant. SMRs increased with time since first exposure and with duration of exposure. An increase in stomach cancer mortality with time since first exposure to mineral wool in a plant in Germany was reported by Claude and Frentzel-Beyme (1986, as cited in IARC 1988/Doc. H-043, p. 145).

Mineral wool has also been shown to cause cancer in rats treated by several routes. In a group of 48 rats exposed by inhalation to 10 mg/m3 rockwool (71 percent of fibers between >5 µm and $<20 \mu m$ in length, 58 percent $< 1 \mu m$ in diameter) for 7 hours per day for 5 days/ week for 12 months, two developed lung adenomas (one tending toward malignant) in the 500-1000 days after the start of exposure. In a group of 48 positive control rats treated with chrysotile (16 percent ≥ 20 µm in length, 29 percent > 0.5 µm in diameter), 11 developed adenocarcinomas and 1 an adenoma (also tending toward malignant). There were no tumors in untreated controls (Wagner et al. 1984, as cited in IARC 1988/Doc. H-043, p. 99). Three of 48 rats treated by intrapleural injection with rockwool coated with resin (70 percent < 5 µm in length, 52 percent < 0.6 µm in diameter) developed mesotheliomas. Two of 48 rats treated with rockwool from which the resin had been removed (70 percent < 5 µm in length, 58 percent < 0.6 µm in diameter) developed mesotheliomas, and 6 of 48 animals treated with chrysotile developed mesotheliomas. There were no tumors in slagwool- or saline-treated rats (Wagner et al. 1984, as cited in IARC 1988/Doc. H-043, p. 100). Pott et al. (1987, as cited in IARC 1988/Doc. H-043, p. 100) treated rats with either fine (median length 14 µm. median diameter 1.5 µm) or coarse (median length 26 µm, median diameter 2.6 µm) slagwool by intraperitoneal (i.p.) injection. With the finer fibers, 2/99 rats developed sarcomas, mesotheliomas, or

carcinomas. Six of 99 animals treated with the coarser fibers developed tumors. There were no tumors in controls.

In rats treated by the i.p. (intraperitoneal) route with rockwool (median length 20 µm, median diameter 1.8 µm), tumors of the abdominal cavity developed in 32/53 animals. Salinetreated controls developed tumors in 2/ 102 rats. Injection of actinolite or chrysotile induced tumors in 20/36 and 31/36 animals, respectively (Pott et al. 1987, as cited in IARC 1988/Doc. H-043, p. 100). Rats injected three times with 75 mg of rockwool (median length 23 um. median diameter 1.9 µm) or once with 10 mg of a fine fraction (median length 4.1 μm, median diameter 0.64 μm) rockwool developed tumors of the abdominal cavity in 45/63 and 6/45 cases, respectively. The incidence in the saline-treated control group was 3/54 (Pott et al. 1987, as cited in IARC 1988/ Doc. H-043, p: 100).

Based on the lack of reported adverse health effects in epidemiologic studies, the ACGIH (1986/Doc. H-020, Ex. 1-3, p. 414) considered mineral wool to be essentially a nuisance dust and applied a 10 mg/m3 TLV&-TWA. NIOSH does not have a REL for mineral wool; however, NIOSH (Doc. H-020, Ex. 8-47) cited recent animal and epidemiological studies indicating the possible carcinogenicity of mineral wool and pointed to statements by Doll (1987/Doc. H-043, Ex. 1-11) that "* * * it is likely that man-made mineral fiber may have about the same carcinogenic potential as asbestos fibers of the same dimension, and that levels of 0.2 f/cc or less in industry are unlikely to produce a measurable risk after 20 years of exposure." NIOSH (Doc. H-020, Ex. 8-47) concluded (citing Doll) that to provide the degree of protection that OSHA believes is necessary for worker health, the PEL should be 0.2 f/cc. NIOSH (Doc. H-020, Ex. 8-47, Table N6B) also believes that a full 6(b) rulemaking is needed for mineral wool. The Thermal Insulation Manufacturers Association (Doc. H-020, Ex. 3-743, p. 9) commented in the earlier rulemaking that OSHA should adopt NIOSH's fibrous glass REL of 3 f/cc for mineral wool. Manville (Doc. H-020, Ex. 8-56) stated that "in March, 1988, Manville recommended to its customers a Workplace Exposure Guideline of 1.0 f/ cc for mineral wool" as part of its "commitment to strive for, and realize the lowest achievable exposure to any given substance * * *." E.I. du Pont de Nemours & Company has an Acceptable Exposure Level of 1.0 f/cc for mineral

wool fibers (personal communication from Freida Fisher-Tyler, 1991).

The International Agency for Research on Cancer (IARC 1988/Doc. H-043), in evaluating the carcinogenicity of mineral wool, has concluded that mineral wool is "possibly carcinogenic to humans (Group 2B)."

OSHA believes, on the basis both of animal and human evidence, that a link between respiratory disease and exposure to mineral wool exists. Therefore, OSHA is proposing that a 1 f/cc 8-hour TWA for the respirable fibers of mineral wool (fibers less than 3.5 micrometers in diameter and greater than 10 micrometers in length) be established as the PEL for mineral wool to protect workers in general industry. construction, maritime, and agriculture from the significant risk of nonmalignant (and possibly malignant) respiratory disease. Since NIOSH has no counting method for mineral wool, OSHA is soliciting comments on potential counting methods. OSHA will continue to evaluate the scientific evidence regarding the risk of mineral woolinduced nonmalignant and malignant respiratory disease and will, at the time of the final rule, establish a new limit for this substance if the Agency determines that this limit will substantially reduce significant risk. If future information and priorities indicate the need for a more restrictive standard for mineral wool. OSHA will initiate individual-substance rulemaking for this substance.

NICKEL (SOLUBLE COMPOUNDS) CAS: 7440–02–0; Chemical Formula: Varies

H.S. No. 1283

OSHA's PEL in the construction and maritime industries for soluble nickel compounds (measured as Ni) is 1 mg/m³ as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 0.1 mg/m³ for these substances. NIOSH recommends that exposure to any form of inorganic nickel be maintained at or below 0.015 mg/m³. OSHA is proposing to revise its PEL in construction and maritime to 0.1 mg/m³ as an 8-hour TWA and to extend this limit to agriculture. This is the limit recently established for the soluble nickel compounds in general industry.

A variety of toxic effects results from exposure to soluble nickel compounds. Soluble nickel salts cause contact dermatitis in sensitized individuals and eye irritation (ACGIH 1986/Ex. 1–3, p. 422). Cases of asthmatic lung disease have been reported among nickel-plating workers (EPA 1986a/Ex. 1–1132). OSHA's proposal to lower the PEL for soluble nickel compounds to 0.1 mg/m³

is based primarily on evidence that exposure to soluble nickel at low levels and for relatively short durations causes pathological changes in the lungs of experimental animals. In addition, OSHA has reviewed several animal and human studies designed to investigate the carcinogenic potential of soluble nickel compounds. Three soluble nickel compounds have been tested for their carcinogenic potential: nickel chloride, nickel sulfate, and nickel acetate. Some sparingly soluble compounds, nickel carbonate and nickel hydroxide, have also been studied. The results of these animal studies suggest that some soluble nickel compounds are potentially carcinogenic; however, the data are derived predominantly from injection studies, and the results are often conflicting. Results from occupational studies on soluble nickel compounds are also conflicting and are confounded by the presence of several types of nickel compounds in the facilities studied. OSHA's preliminary findings on the toxicological evidence for the soluble nickel compounds are presented below.

Bingham and Zerwas et al. (1972/Ex. 1-204) exposed rats by inhalation to 0.1 mg/m³ nickel chloride for 12 hours per day for two weeks. Animals showed evidence of pulmonary irritation and damage in the form of marked mucus secretion, hyperplasia, and accumulations of alveolar macrophages. Fluid obtained by lung lavage appeared very cloudy and viscous due to the presence of free alveolar cells. Rats and guinea pigs exposed daily to 1.0 mg/m3 nickel chloride (measured as Ni) for six months showed increased lung weight, which is an indication of pulmonary damage and hyperplasia (Clary 1977, as cited in ACGIH 1986/Ex. 1-3, p. 422); exposed rats also developed signs of interstitial fibrotic lesions. Rabbits inhaling 0.3 mg/m³ nickel chloride (measured as Ni) aerosol for 30 days showed a doubling in alveolar cell number and in the volume of alveolar epithelial cells, as well as nodular accumulation of macrophages and laminated structures (Johansson, Curstedt, Robertson, and Camner 1983/ Ex. 1-273). These studies clearly show that exposure at or below 1.0 mg/m3. even for durations considerably less than a working lifetime, is associated with increased cell turnover and pathological changes in the lung. These pathological changes, in particular the appearance of the fibrotic lesions observed in animals exposed to low levels of soluble nickel salts, indicate that lung damage has occurred and suggest that significant decrements in lung function may result from prolonged

exposure to these low levels.
Furthermore, the appearance of
hyperplasia is indicative of abnormal
cell growth and suggests the presence of
pre-cancerous lesions.

Nickel chloride has been reported to be mutagenic in Salmonella typhimurium and Cornebacterium but negative in E. coli (EPA 1986a/Ex. 1–1132). The positive studies are not considered conclusive, however, because the S. typhimurium report is an abstract lacking detailed data and Cornebacterium is not the usual species used in these tests. Amacher and Paillet (1980/Ex. 1–286) reported that nickel chloride was mutagenic in mouse lymphoma cells and demonstrated a dose-response relationship for this endpoint.

Some in vitro studies using soluble nickel compounds report finding chromosomal aberrations (EPA 1986a/Ex. 1–1132). These studies do not, however, demonstrate a dose-response relationship or statistical significance, which weakens their findings. Several in vivo studies have failed to detect chromosomal aberrations (EPA 1986a/Ex. 1–1132). However, several in vitro studies on nickel sulfate and nickel chloride have reported findings of sister chromatid exchanges (EPA1986a/Ex. 1–1132).

Some animal studies involving soluble nickel compounds suggest that these compounds are carcinogenic in animals. Strain A mice receiving intraperitoneal injections of nickel acetate had an increased rate of lung adenomas and adenocarcinomas that was statistically significant in the high-dose group (Stoner, Shimkin, Troxell et al. 1976/Ex. 1–203). The animals were injected three times per week for eight weeks at doses of 72, 180, or 360 mg/kg.

EPA (1986a/Ex. 1-1132) reported a study in which rats were given monthly intramuscular injections of 35 mg/kg nickel acetate for four to six months (Haro, Furst, and Falk 1968/Ex. 1-1022). Twenty-two percent of the treated rats developed sarcomas. Payne (1964/Ex. 1-200) observed tumor responses in rats after intramuscular implantation of 7 mg nickel acetate, nickel sulfate, nickel chloride, or nickel carbonate. Implantsite sarcomas developed in one of 35 rats exposed to nickel acetate, one of 35 rats exposed to nickel sulfate, none of 35 rats exposed to nickel chloride, and four of 35 rats exposed to nickel carbonate.

Results of other studies on nickel sulfate have been negative. Three studies used intramuscular injection in rats and reported that no tumors developed in the treated group (Gilman 1962/Ex. 1–205; Gilman 1966, as cited in EPA 1986/Ex. 1–1132; Kasprzak, Gabryel, and Jaraczewska 1983/Ex. 1– 201). An ingestion study also reported no tumors among treated rats or dogs (Ambrose, Larson, Borzelleca et al. 1976/Ex. 1–211).

Gilman (1966, as cited in EPA 1986a/ Ex. 1-1132) administered 5 mg nickel hydroxide to rats by intramuscular injection in each thigh. Sarcomas developed at 19 out of 40 injection sites. Kasprzak, Gabryel, and Jaraczewska (1983/Ex. 1-201) gave rats intramuscular injections of nickel hydroxide in gel, crystalline, or colloidal form. Five out of 19 animals receiving the gel developed sarcomas (two with metastasis to the lung), three out of 20 receiving the crystalline form developed sarcomas (one with metastasis to the lung), and none of 13 rats receiving the colloid developed tumors.

In the prior rulemaking, some commenters (Exs. 3–915, 167, 3–668) discussed the limitations of the animal data. These commenters noted that soluble nickel compounds have produced tumors in animals only by injection and that the results among studies are conflicting. OSHA recognizes many of these limitations of the data. Although the animal data are "too limited to support any definitive judgment regarding * * * [the] carcinogenic potential [of soluble nickel compounds]," EPA noted:

the observation of pulmonary tumors in strain A mice from the administration of nickel acetate by intra-peritoneal injections and the ability of nickel acetate to transform mammalian cells in culture and to inhibit RNA and DNA synthesis provides limited evidence for the carcinogenicity of nickel acetate and supports a concern for the carcinogenic potential of other soluble nickel compounds (EPA 1986a/Ex. 1–1132, p. 8–229).

OSHA agrees with EPA's assessment that, although some studies are suggestive of a carcinogenic effect and an ability of soluble nickel to transform cells, overall the animal data are too equivocal at this time to support any firm conclusions that soluble nickel compounds do or do not cause cancer in experimental animals.

In addition to the animal evidence described above, OSHA reviewed studies conducted on workers exposed to soluble nickel compounds. Electrolysis workers at a refinery in Kristiansand, Norway, experienced a higher lung cancer risk than employees from the same facility who worked in three other job categories, including roasting and smelting workers (Magnus, Andersen, and Hogetveit 1982/Ex. 1–241). Electrolysis workers were exposed to an aerosol composed predominantly

of nickel sulfate, which was estimated to contain soluble nickel at a concentration of 0.2 mg/m3 (EPA 1986a/ Ex. 1-1132); these workers also had higher plasma and urine levels of nickel than did roasting and smelting workers, who were predominantly exposed to insoluble nickel subsulfides and oxides. However, exposure to nickel subsulfide and oxides may have occurred in the electrolysis building, and the electrolysis workers may also have worked in other process departments (Grandjean, Andersen, and Nielsen 1988/Ex. 1-207). Roasting and smelting workers were exposed to an estimated average of 0.5 mg/m3 (as Ni) of roasting dust.

The standardized mortality ratios (SMRs) for lung cancer were 550 for electrolysis workers, 390 for other process workers, and 360 for roasting and smelting workers. The pattern of SMRs for nasal cancer, which is a rare form of cancer in humans, was different among these groups: 2600 for electrolysis workers, 2000 for other process workers, and 4000 for roasting and smelting workers. The results seem consistent with studies that show that roasting and smelting workers have the highest concentrations of nickel in the nasal mucosa, presumably because of the relatively larger particles resulting from roasting. Conversely, electrolysis workers, who showed a larger lung cancer risk than roasting and smelting workers, have higher plasma and urine levels of nickel, suggesting that nickel aerosolized by this process penetrates to the deep lung (EPA 1986a/Ex. 1-1132).

The primary impetus to revise the PEL for soluble nickel is to protect workers in construction and maritime, and in agriculture, from soluble nickel's respiratory effects; the other objective is to make the limit for these compounds consistent across all sectors. OSHA preliminarily concludes that the available studies clearly demonstrate that exposure to soluble nickel compounds at the current construction and maritime PEL of 1 mg/m3 presents a significant risk of lung irritation accompanied by pathological changes that may presage cancer. OSHA has preliminarily determined that these effects constitute material impairments of health and functional capacity. OSHA also preliminarily concludes that the proposed rule's reduction in the PEL will substantially reduce these significant risks. Accordingly, OSHA is proposing an 8-hour TWA PEL of 0.1 mg/m3 (measured as Ni) for soluble nickel compounds in the construction, maritime, and agriculture industries. Promulgation of this limit will make the

PEL for these substances consistent across all OSHA-regulated sectors. NITROGEN DIOXIDE CAS: 10102-44-0; Chemical Formula: NO₂

H.S. No. 1289

The limit for nitrogen dioxide in the construction and maritime industries is a 5 ppm ceiling. There is no limit in agriculture. The ACGIH has a 3 ppm 8-hour TLV*—TWA and a 5 ppm TLV*—STEL for this substance. NIOSH has a REL of 1 ppm as a 15-minute ceiling. The Agency is proposing a 1 ppm STEL for nitrogen dioxide in the construction, maritime, and agriculture industries. NIOSH (Ex. 8–47, Table N1) agreed with the selection of this PEL when the Agency recently established it for general industry.

Nitrogen dioxide is a reddish-brown gas at room temperature that condenses to a brown liquid and freezes to a colorless solid. Nitrogen dioxide has found use as a catalyst in oxidation reactions, an inhibitor to prevent polymerization of acrylates during distillation, a nitrating agent, an oxidizing agent, a rocket fuel and a flour bleaching agent and in the manufacture of liquid explosives (Braker and Mossman 1980, p. 531). Nitrogen dioxide also occurs as a component of diesel exhaust.

OSHA's current 5-ppm ceiling limit in construction and maritime is based primarily on the animal studies of Gray. MacNamee, and Goldberg (1952/Ex. 1-154), Gray, Goldberg, and Patton (1954/ Ex. 1-165), and Wagner, Duncan, Wright, and Stokinger (1965/Ex. 1-102). Gray, MacNamee, and Goldberg (1952/ Ex. 1-154), and Gray, Goldberg and Patton (1954/Ex. 1-165) demonstrated lung injury among rats exposed for 8 or more weeks to an 8-ppm concentration of a mixture of NO2 and nitric acid, but these authors did not see such lesions in rats exposed for six months to 4-ppm concentrations of this mixture. Wagner, Duncan, Wright, and Stokinger (1965/Ex. 1-102) reported transient and mild acute effects but no adverse chronic effects in rats exposed to 1 ppm, 5 ppm, or 25 ppm pure NO2 for 18 months. The ACGIH's recommendation (from which OSHA's limit in construction and maritime derives) that the 5-ppm TLV® be defined as a ceiling rather than as an 8-hour TWA was based on reports that NO2 accelerated lung tumor development among lung-tumor-susceptible mice; in the late 1960s, the ACGIH believed that a TLV®-ceiling value would minimize the risk of accelerating lung tumor development.

The current ACGIH TLV®s for NO₂ are a 3-ppm 8-hour TWA and a 5-ppm

15-minute STEL, and these limits are based on human studies that indicate that normal respiratory function may be compromised at exposures below the current OSHA limit of 5 ppm NO2. In particular, Kosmider, Ludyga, Misiewicz et al. (1972/Ex. 1-224) reported a slight reduction in vital capacity and maximum respiratory volume in 70 men exposed to 0.4- to 2.7-ppm concentrations of the oxides of nitrogen 6 to 8 hours daily for 4 to 6 years. These authors also reported an unspecified number of cases of chronic bronchitis among men in this group. Another study by Vigdortschik, Ancheeva, Matussevistch et al. (1937/Ex. 1-49) reported possible cases of chronic bronchitis and emphysema among 127 workers generally exposed below 2.8 ppm NO2; these workers were also believed to be exposed to sulfuric acid mist at levels sufficient to cause dental

The NIOSH REL for NO2 of 1 ppm as a 15-minute STEL is based on the two human studies discussed above, as well as some human studies involving shortterm exposure. Abe (1967/Ex. 1-98) found a 40-percent decrease in effective lung capacity among healthy adult males 30 minutes after a 10-minute exposure to 4- to 5-ppm NO2. Expiratory and inspiratory maximum viscous resistance also increased by 92 percent after exposure. NIOSH (1976j/Ex. 1-265) concluded that Abe's results "document a definite and undesirable effect" at exposures approaching or below the current OSHA limit.

A series of major studies by von Nieding also indicates the need for a 1 ppm STEL. A significant decrease in carbon monoxide diffusing capacity was observed by von Nieding, Krekeler, Fuchs et al. (1973/Ex. 1–770) in healthy adults exposed to 5 ppm for 15 minutes. Two studies (von Nieding, Wagner, Krekeler et al. (1971/Ex. 1–1204) and von Nieding and Krekeler (1971/Ex. 1–1175)) report significant increases in airway resistance among 88 chronic bronchitis patients after a 15-minute exposure to a concentration of NO₂ as low as 1.5 ppm.

NIOSH (1976)/Ex. 1–265) concluded that the specific concentration of NO₂ required to produce pulmonary changes in normal, healthy adults is unknown, but "is likely to be about the same or perhaps a slightly higher concentration than the one inducing pulmonary changes in humans with existing chronic bronchitis" (1.5 ppm). Therefore, NIOSH recommended a 1-ppm 15-minute short-term limit for nitrogen dioxide. To provide additional support for a short-term rather than a TWA limit, NIOSH cited several animal studies that

indicate that the toxic effects associated with exposure are primarily determined by peak, and not average, NO2 concentrations. NIOSH (Ex. 150) also notes that, in 1984, the World Health Organization, after an independent review of cross-sectional occupational health surveys, recommended a shortterm occupational exposure limit of 1.8 mg/m3 (0.9 ppm) for NO2 and 8-hour TWA limit of 0.9 mg/m3 (0.45 ppm).

The EPA limit for NO2 is 0.053 ppm averaged over 1 year. EPA considers 2 ppm for 1 hour to be a significant harm level that requires an emergency response. EPA's 1982 staff paper concludes that the 1971 von Nieding et al. (Ex. 1-1204) study "provides convincing evidence that chronic bronchitics exposed to NO2 concentrations of 1.6 ppm or greater for approximately 3 minutes experience increases in airway resistance" (Ex. 3-2e, p. 18). A number of other studies were also cited by EPA (Ex. 3-2f) in which healthy adults were exposed to NO2 concentrations in the range of 0.5 to 2.5 ppm. Folinsbee, Horvath, Bedi, and Delehunt (1978, as cited in Ex. 3-2e) reported no significant physiological changes in healthy adults exercising for up to one hour during a two-hour exposure to 0.6 ppm NO2. Suzuki and Ishikawa (1965, as cited in Ex. 3-2e) reported a 50-percent increase in inspiratory flow resistance in healthy adults 10 minutes after a 10-minute exposure to an NO2 concentration between 0.7 and 2 ppm. Small changes in pulmonary function and a slight increase in the prevalence of respiratory symptoms occurred among healthy adults exposed to 1 ppm NO2 for 2 hours (Hackney, Thiede, Linn et al. 1978, as cited in Ex. 3-2e). Beil and Ulmer (1976, as cited in Ex. 3-2e) reported a statistically significant increase in airway resistance among healthy adults following exposure to 2.5 ppm NO2 for two hours, but not following exposure to 1 ppm. Based on their review of these data, EPA concluded:

[T]he lowest level of NO2 exposure that credible studies have associated with measurable impairment of pulmonary function appears to be in the range of 1.0-1.8 ppm * * * (Ex. 3-2e, p. 18).

OSHA has also reviewed the most recent analysis of NO2 toxicity conducted by the National Academy of Science's (NAS) Committee on Toxicology for the Department of Defense (Emergency and Continuous Exposure Guidance Levels for Selected Airborne Contaminants, Vol. 4, pp. 83-96, National Academy Press 1985). In this review, the NAS concluded that exposures to NO2 at levels between 0.5

and 1.5 ppm have demonstrated "little or supported by NIOSH and the World no persistent change in pulmonary function" (NAS 1985, p. 89). The NAS Committee on Toxicology recommended short-term public emergency guidance levels (SPEGLs) for NO2 of 1 ppm. averaged over a 60-minute period, and 0.12 ppm as an 8-hour average.

In the prior rulemaking, several industry commenters objected to OSHA's proposal to establish a PEL at the level of NIOSH's REL for NO2; these commenters believed that the ACGIH TLV*s of 3 ppm TWA and 5 ppm STEL are sufficiently protective. These commenters pointed to the Linn and Hackney (1984, 1985) papers (subsequently published), which indicated that healthy adults and asthmatics studied did not have pulmonary effects while exercising and being exposed to 4 ppm NO2.

The AFL-CIO supported OSHA's proposed limits (Ex. 64) in the earlier rulemaking. The AFL-CIO believes that the same studies demonstrate the need

for a 1 ppm STEL.

OSHA preliminarily concludes that a 1 ppm STEL is necessary to prevent significant risk of material health impairment. Many of the cohort studies indicate substantial reductions in lung function, a material impairment of health, as well as exacerbation of other health effects, at levels only slightly above 2 ppm. The von Nieding study indicates substantial reductions in lung function in chronic bronchitics exposed for 15 minutes to 1.5 ppm. A substantial percentage of the work force suffers from chronic bronchitis. Beil and Ulmer show reductions in lung function in healthy adults at exposures of 2.5 ppm. Suzuki and Ishikawa (1965) and Rokaw et al. (1968) also show pulmonary function declines at concentrations below 5 ppm. There are also studies showing more minor reductions in lung function in healthy adults at lower levels.

The Linn and Hackney studies present results that conflict to some extent with the findings of the studies described above, i.e., Linn and Hackney show no decline in pulmonary function on exposure to 4 ppm NO2. However, because so many studies of high quality demonstrate substantial lung function declines at low NO2 exposure levels, OSHA preliminarily concludes that the weight of the evidence already suggests that substantial declines occur on exposure to NO2 levels as low as 1.5 ppm. In consequence, the Agency believes that the 1 ppm STEL is necessary to prevent significant risk of material health impairment. As discussed above, this view is clearly

Health Organization. OSHA's preliminary finding is also consistent with the conclusions reached by EPA and the National Academy of Science.

Thus, OSHA preliminarily concludes that the former 5-ppm ceiling limit for NO2 in construction and maritime is not sufficient to protect employees from experiencing increased airway resistance. OSHA also preliminarily concludes that the risk of increased airway resistance in construction, maritime, and agriculture will be substantially reduced by promulgation of the proposed 1-ppm short-term limit for NO2; a short-term limit is clearly indicated for NO2 because all of the studies cited above demonstrate that increased airway resistance is associated with exposure to NO2 for durations of between 3 minutes and 2 hours. OSHA considers the increased airway resistance caused by exposure to NO2 to be a material impairment of health. Therefore, to reduce the significant risk associated with shortterm exposure to NO2, the Agency is proposing a 1-ppm limit, averaged over a 15-minute period, for nitrogen dioxide in the construction, maritime, and agricultural industries. Promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

OXYGEN DIFLUORIDE CAS: 7783-41-7; Chemical Formula: OF2 H.S. No. 1300

The PEL for oxygen difluoride in the construction and maritime industries is 0.05 ppm as an 8-hour TWA. The ACGIH has established a limit of 0.05 ppm as a ceiling value. OSHA is proposing a permissible exposure limit of 0.65 ppm as a ceiling for oxygen difluoride in the construction, maritime, and agricultural industries. NIOSH has no REL but concurred (Ex. 8-47, Table N1) with the selection of this limit when the Agency recently established it in general industry.

Oxygen difluoride is an unstable, colorless gas with a foul odor. Oxygen difluoride is used as an oxidizer for rocket propellants (Genium MSDS 1988, No. 228).

Oxygen difluoride is a substance having extremely high acute toxicity; it is an acute irritant and causes fatal pulmonary edema and hemorrhage in animals exposed to 0.5 ppm for a few hours (ACGIH 1986/Ex. 1-3). A single exposure to 0.1 ppm also had an effect on the lungs; animals acutely exposed to oxygen difluoride have also exhibited gross changes in the kidneys and internal genitalia (LaBelle, Metcalf,

Suter, and Smith 1945, as cited in ACGIH 1986/Ex. 1-3, p. 452; Lester and Adams 1965/Ex. 1-963).

Because of the extreme acute toxicity of this compound and the effects seen at 0.1 ppm, OSHA believes that the current 8-hour TWA PEL of 0.05 ppm in construction and maritime is not sufficiently protective of workers; this limit would permit brief periods of high exposure that have been associated with severe lung damage in animals. Furthermore, workers in agriculture are currently unprotected from oxygen difluoride's effects. The Agency has preliminarily determined that these respiratory effects constitute material impairments of health. Therefore, to reduce the significant risk of acute lung damage associated with brief excursion exposures to oxygen difluoride, OSHA is proposing a ceiling limit of 0.05 ppm for this substance in the construction, maritime, and agricultural industries. Promulgation of this limit will also make OSHA's PEL for this substance consistent across all regulated sectors." OZONE

CAS: 10028-15-6; Chemical Formula: O₃ H.S. No. 1301

The current OSHA PEL for ozone in construction and maritime operations is 0.1 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH has an 8-hour TLV*-TWA of 0.1 ppm and a 0.3 ppm TLV*-STEL for ozone. NIOSH has no REL. In construction and maritime, OSHA is retaining its permissible exposure limit of 0.1 ppm TWA and proposing to add a 0.3 ppm STEL; the Agency is also proposing to extend these limits to agriculture. Promulgation of these limits will make the PELs for ozone consistent across all OSHA-regulated sectors.

Ozone is a liquid or an explosive gas. Ozone is used as a disinfectant for air and water because of its oxidizing power. It is also used for bleaching waxes, textiles, oils, and in organic syntheses (Merck 1983, p. 6850).

OSHA is retaining the 8-hour TWA limit of 0.1 ppm in construction and maritime, proposing a 15-minute STEL of 0.3 ppm in these two sectors, and is also proposing to extend both limits to agriculture, based on observations that significant declines in pulmonary function can result from repeated intermittent exposures or even from a single short-term exposure (Bils 1970/ Ex. 1-58; Jaffe 1967/Ex. 1-101; Griswold, Chambers, and Motley 1957/Ex. 1-128). OSHA believes that, in the absence of a STEL, employees in these sectors will continue to be at significant risk of material impairment in pulmonary functional capacity associated with

short-term exposures that could occur if exposures are controlled only by an 8-hour TWA. Thus the Agency believes that it is necessary to supplement an 8-hour TWA PEL of 0.1 ppm with a 15-minute STEL of 0.3 ppm to substantially reduce this risk. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors. PARAQUAT CAS: 4685–14–7; Chemical Formula: H.S. No. 1303

OSHA's current limit for paraquat (respirable fraction) in the construction and maritime industries is 0.5 mg/m³ as an 8-hour TWA, with a skin notation. There is no limit in agriculture. The ACGIH has established a TLV® of 0.1 mg/m³ as an 8-hour TWA. NIOSH has no REL for paraquat. In construction, maritime, and agriculture, the Agency is proposing an 8-hour TWA permissible exposure limit of 0.1 mg/m³ for this substance, with a skin notation. NIOSH

concurred (Ex. 8-47, Table N1) with this limit when the Agency recently established it in general industry.

Paraquat refers to a group of compounds that are odorless, yellow solids. The principal compounds are: 1,1'-dimethyl-4,4'-bipyridinium; 1,1'dimethyl-4,4'-bipyridinium bis (methyl sulfate); and 1,1'-dimethyl-4,4'bipyridinium dichloride. Paraquat is used as an insecticide, either alone or in combination with long-acting herbicides in no-till farming. Paraquat also finds use in industrial and noncrop weed control; in deciduous orchards; and on cotton, soybeans, potatoes, and seed crops (ACGIH 1986, p. 456; Clayton and Clayton 1981, p. 2751). When used in pesticidal applications, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

The toxicity of paraquat depends on the compound's cationic moiety. Acute oral toxicity is reported as 30 mg/kg ion (as cation) for guinea pigs and 127 mg/ kg ion for female rats, while the dermal LD50 in rabbits is 240 mg/kg ion (Clark 1964, as cited in ACGIH 1986/Ex. 1-3, p. 456; Clark, McElligott, and Hurst 1966/ Ex. 1-503; McElligott 1965, as cited in ACGIH 1986/Ex. 1-3, p. 456). The oral LD₅₀ in monkeys is 50 mg/kg (Clayton and Clayton 1981, p. 2754). Paraquat can penetrate broken skin after it has broken down the skin's usual barriers (Swan 1969/ Ex. 1-576; Clark, McElligott, and Hurst 1966/Ex. 1-503).

By inhalation or intratracheal injection, paraquat is very toxic because of its irritant properties (Gage 1968/Ex. 1–508). Rats exposed once for six hours to a concentration of 1 mg/m³ died if the

aerosol contained particles with diameters of 3 to 5 microns (Gage 1968/Ex. 1–508). Rats exposed 6 hours/day for 3 weeks to the same aerosol at 0.4 mg/m³ exhibited signs of pulmonary irritation; no effects were observed on the same exposure regimen when the concentration was reduced to 0.1 mg/m³ (Gage 1968/Ex. 1–508).

When particles in the aerosol are not of respirable size, paraquat's toxicity is greatly reduced. The 4-hour LC₅₀ for rats is 6400 mg/kg, and dogs, rats, and guinea pigs tolerated 3 weeks of daily exposures to 100 mg/m³ without apparent pulmonary effect (although nosebleeds were observed) (Palazzolo 1965, as cited in ACGIH 1986/Ex. 1–3, p.

Dietary administration of paraquat doses ranging from 300 to 700 ppm for 90 days caused dose-related effects ranging from pulmonary edema to intra-alveolar hemorrhage and death in experimental animals (Kimbrough and Gaines 1970/Ex. 1–560). Paraquat's teratogenic potency in mice is low (Bus and Gibson 1975/Ex. 1–539), although 100 ppm administered in the drinking water of pregnant rats increased postnatal mortality significantly (Bus and Gibson 1975/Ex. 1–539).

In humans, 69 accidental deaths and 81 suicides were attributed to the effects of paraquat exposure in the period before 1972 (Chipman Chemicals 1972, as cited in ACGIH 1986/Ex. 1-3, p. 456). Bouletreau, Ducluzeau, Bui-Xuan et al. (1977/Ex. 1-538) reported 31 cases of renal insufficiency, and a spray applicator was killed when he absorbed a lethal dose of inadequately diluted paraquat through the skin (Jaros 1978/ Ex. 1-513). Workers using a 0.05- to 1percent solution of paraquat developed skin and mucous membrane irritation but experienced no symptoms of systemic poisoning (Howard 1978/Ex. 1-512). Fugita, Suzuki, and Ochiai (1976, as cited in ACGIH 1986/Ex. 1-3, p. 456) reported five cases of reversible keratoconjunctivitis, with corneal injury, after one month of exposure to paraquat.

OSHA is proposing an 8-hour TWA limit of 0.1 mg/m³ for paraquat, with a skin notation, for the construction, maritime, and agriculture industries. The Agency preliminarily concludes that this limit will protect workers in these sectors from the significant risk of skin, eye, and pulmonary irritation observed in animals exposed to paraquat aerosols of respirable size. The Agency considers the irritant effects of paraquat to be material impairments of health. The skin notation for this substance is necessary because of paraquat's capacity to

penetrate the skin. Promulgation of this limit will also make the PEL for paraquat consistent across all OSHA-regulated sectors.

SILICA, AMORPHOUS-DIATOMACEOUS EARTH CAS: 68855-54-9; Chemical Formula: SiO₂

H.S. No. 1352

OSHA's permissible exposure limit for amorphous silica, diatomaceous earth in constituction and maritime is 20 million particles per cubic foot (mppcf). There is no PEL in agriculture. The ACGIH has a TLV*-TWA of 10 mg/m³ for this substance as an 8-hour limit, measured as total dust; NIOSH has no REL. OSHA is retaining the 8-hour TWA limit of 6 mg/m³ (which is equivalent to 20 mppcf) for amorphous silica, diatomaceous earth in construction and maritime and is proposing this limit in agriculture. This is the limit recently established for this substance in general industry.

Amorphous silica is a non-crystalline, colorless to gray, odorless powder composed of the skeletons of prehistoric plants known as diatoms. Amorphous silica is used in the manufacture of glass, in refractories, abrasives, ceramics and enamels, for decolorizing and purifying oils, and in scouring and grinding compounds (Merck 1983, p. 122; NIOSH/OSHA Occupational Health

Guideline 1981, p. 1).

The amorphous forms of silica are believed to be fibrogenic under some circumstances but are generally considered less fibrogenic than the crystalline forms (IARC 1987, Vol. 42, p. 39). The literature contains some reports demonstrating the fibrogenicity of the amorphous forms of silica and others showing no fibrotic effects. For example, the intratracheal instillation of diatomaceous earth dust in animals of several species has caused fibrosis (Gardner 1942, as cited in ACGIH 1986/ Ex. 1-3, p. 520) and silicosis (Kovalevich 1957, as cited in ACGIH 1986/Ex. 1-3, p. 520). Another study (Tebbens and Beard 1957/Ex. 1-531) exposed guinea pigs to diatomaceous earth at an average concentration of 60 mg/m3 for 37 to 50 weeks and found both accumulations of dust-laden macrophages and alveolar epithelialization but no fibrosis at autopsy. Rabbits inhaling 40 mg/ml amorphous silica dust for 1100 days showed a diffuse tissue reaction without fibrosis, but intratracheal instillation of amorphous silica particles caused pulmonary lesions in rats within 6 months of the beginning of exposure (IARC 1987, Vol. 42, p. 39).

Cooper and Cralley (1958/Ex. 1-1145) reported linear-nodular changes in the lungs of workers exposed only to

amorphous (noncrystalline) silica at unspecified concentrations for 5 years or more. Several other studies (Vigliani and Mottura 1948/Ex. 1–534; Gardner 1942, as cited in ACGIH 1986/Ex. 1–3, p. 520) have reported that diatomite workers develop mild silicosis after such exposure or, in some cases, show no signs of serious lung pathology. For example, Kovalevich (1957, as cited in ACGIH 1986/Ex. 1–3, p. 520) reported silicosis in diatomite workers, while Gardner (1942, as cited in ACGIH 1986/Ex. 1–3, p. 520) found no evidence of lung pathology in exposed workers.

OSHA preliminarily concludes that the evidence suggests that amorphous silica (diatomaceous earth) is a potential respiratory toxin in many exposed workers. OSHA therefore believes that workers in agriculture are at significant risk of experiencing these adverse health effects, and that establishing the proposed 8-hour TWA limit of 6 mg/m3 for amorphous silica is necessary to reduce the significant risk that agricultural workers will experience this material health impairment. OSHA is also changing the units used to express the PEL (but not the value of the PEL) in construction and maritime. In the previous rulemaking, NIOSH (Ex. 8-47, Table 1) concurred that this limit was appropriate for this substance and that expressing the limit in mg/m3 than in mppcf would facilitate sampling and analysis. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

SILICA, AMORPHOUS, PRECIPITATED OR GEL

CAS: None; Chemical Formula: SiO₂ H.S. No. 1353

OSHA has no limit in the construction, maritime, or agriculture industries for amorphous silica in precipitated or gel form. The ACGIH's TLV*-TWA for this substance is 10 mg/m³ as an 8-hour TWA limit, measured as total dust. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 10 mg/m³ (total dust) for amorphous silica in precipitated or gel form in construction, maritime, and agriculture; this limit is identical to the one recently established for these forms of silica in general industry.

Both the precipitated and gel forms of amorphous silica are non-crystalline, colorless or white, finely divided powders that are odorless. Precipitated silica is precipitated from aqueous solution, and silica gel is a coherent network of particles of colloidal silica. These forms of silica are used as fillers

in paint, rubber, and paper, as grease thickeners, as diluents for insecticides, and as carrying agents for catalysts (ACGIH 1986, p. 521; NIOSH/OSHA Occupational Health Guidelines 1985, p. 1).

Studies in laboratory animals have shown no fibrosis after intratracheal or intraperitoneal injection of precipitated silica or silica gel (Klosterkotter 1954/ Ex. 1-1156; Klosterkotter 1958/Ex. 1-1039). Schepers and colleagues reported in 1957 that rats exposed for one year and guinea pigs and rabbits exposed for two years to a concentration of 126 mg/ m3 of amorphous silica in precipitated form displayed no pulmonary fibrosis; the effects of exposure were limited to macrophage accumulation and mild proliferation of reticulin fibers (Schepers, Durkan, Delahant et al. 1957/ Ex. 1-755). An unpublished NIOSH study (Groth, Kommineni, Stettler et al. 1979) showed that rats, guinea pigs, and monkeys developed accumulations of macrophages in the lungs after exposure to precipitated silica; in addition, the presence of collagen was seen in a "very few" monkeys. By comparison, collagen was not seen in any animal exposed to silica gel but was seen in significant amounts in monkeys exposed to fumed silica (a crystalline variety of silica).

In a study of human exposures to amorphous silica in precipitated form, no ill effects were reported in 165 workers exposed to an unspecified concentration of this substance for an average of 8.6 years (Wilson, Stevens, Lovejoy et al. 1981/Ex. 1–1177). However, the literature suggests that exposure to all forms of silica dust may produce fibrosis, although exposure to the amorphous forms (such as precipitated or gel) is likely to be less fibrogenic than exposure to the crystalline forms (IARC 1987, Vol. 42, p. 85).

Based on this evidence, OSHA preliminarily concludes that exposure to amorphous silica (in precipitated or gel form) has the potential to cause respiratory effects in exposed workers. OSHA therefore believes that, in the absence of a limit, workers in construction, maritime, and agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that a limit of 10 mg/ m³ for amorphous silica in precipitated or gel form is necessary in construction, maritime, and agriculture to substantially reduce this risk of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for these substances consistent across all regulated sectors.

SILICA, CRYSTALLINE— CRISTOBALITE CAS: 14464–46–1; Chemical Formula: SiO₂ H.S. No. 1354

The OSHA PEL for cristobalite in the construction and maritime industries is based on the formula 250/%SiO2+5 and is measured as millions of particles per cubic foot (mppcf). There is no limit in agriculture. The ACGIH has an 8-hour TLV*-TWA of 0.05 mg/m3, measured as respirable silica dust, and the NIOSH REL for this substance is 50 µg/m3 as a 10-hour TWA. OSHA is proposing an 8hour TWA permissible exposure limit of 0.05 mg/m3 for cristobalite, measured as respirable silica dust, for the construction, maritime, and agriculture industries. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated

Cristobalite, one of the three major crystalline polymorphs of silicon dioxide, is transparent, tasteless, and stable at high temperatures. It occurs naturally in volcanic rock and is used as a filtering and insulating medium and in silicaceous refractory materials for furnace linings and silica bricks (Clayton and Clayton 1981, p. 3020). Cristobalite is also used in the manufacture of water glass, abrasives, ceramics, and enamels (ACGIH 1986, p. 522)

There is widespread agreement in the literature that silica in crystalline form is highly fibrogenic in exposed animals and humans (Merchant 1986, p. 217). The fibrotic disease caused by the inhalation and deposition of silica is called silicosis; silicosis occurs both in acute and chronic form and is often associated with tuberculosis (Merchant 1985, p. 217). Although the human and toxicological literature often fails to distinguish among the three primary crystalline forms of silica (cristobalite, tridymite, and tripoli), a study by Gardner (1938, as cited in ACGIH 1986/ Ex. 1-3, p. 522) that was subsequently confirmed by King, Mohanty, Harrison, and Nagelschmidt (1953/Ex. 1-85) showed that experimental animals injected with cristobalite showed a more severe response than that produced by pure quartz and that the resulting fibrosis that followed was diffuse rather than nodular. OSHA's toxicological writeup for the crystalline forms of silica appears under the entry for "Silica, Crystalline Quartz, Respirable," below; readers are referred to that section for additional details on the toxicology of crystalline silica.

OSHA is proposing to express the limit for cristobalite in mg/m³ rather

than as a formula to simplify employee exposure monitoring in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that, in the absence of a limit, exposure to cristobalite presents a significant risk of silicosis and possible carcinogenicity to agricultural workers. OSHA believes that the promulgation of this proposed limit will substantially reduce this risk. In addition, promulgation of 0.05 mg/m³ for cristobalite will make the PEL for this substance consistent across all regulated sectors.

SILICA, CRYSTALLINE QUARTZ, RESPIRABLE

CAS: 14808–60–7; Chemical Formula: None

H.S. No. 1355

The current OSHA limit for silicacontaining dusts in construction and maritime (there is no limit in agriculture) is a limit expressed in millions of particles per cubic foot (mppcf) and derived from the following formula:

250*

%SiO2+5

* The percentage of crystalline silica in the formula is the amount determined from airborne samples, except in those cases in which other methods have been shown to be applicable.

At one time, the ACGIH also expressed its quartz limit in terms of this formula. However, the current ACGIH TLV*-TWA is 0.1 mg/m³, measured as respirable quartz dust. NIOSH has a REL for this substance of 0.05 mg/m³ as a 10-hour TWA. OSHA is proposing an 8-hour TWA permissible exposure limit of 0.1 mg/m³, measured as respirable quartz, for workplaces in the construction, maritime, and agriculture industries. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Quartz is a colorless, odorless, noncombustible solid. It is used in electronic components; radio and television components; wave filters; as a barrel-finishing abrasive; a piezoelectric control in filters; and in oscillators. Exposure can occur in sand blasting, pottery manufacture, hard rock mining, and in the spraying of vitreous enamels (Genium MSDS 1990, No. 71), as well as in any operation involving the handling, cutting, or shaping of stone. Silica exposures often occur in dusty out-ofdoors environments, and workers in construction and agriculture are exposed to silica in areas where the soil is silicaceous.

Occupational exposure to respirable silica has been known for many years to produce silicosis, a fibrotic disease of

the lungs characterized by the formation of silica-containing nodules (Merchant 1986). Silicosis may occur in both acute and chronic forms (Merchant 1986). The acute form usually occurs after "very high" (not further characterized) exposures lasting for 1 to 3 years; in this form of the disease, intraalveolar deposits, similar to those seen in alveolar proteinosis, develop in exposed individuals (Merchant 1986). The chronic forms of silicosis are more common and are usually seen after 20 to 45 years of exposure to dusts containing 30 percent or less silica. The lesions of chronic silicosis are nodular in form and are generally concentrated in the upper lobes of the lungs. In simple silicosis, nodules are 5 mm or less in diameter and tend not to cause substantial pulmonary deficits (Merchant 1986). As the disease progresses, however, these lesions coalesce to form progressive massive fibrosis; at this stage, the disease is called complicated silicosis, and the pulmonary function of the victim is seriously compromised (Merchant

In the prior rulemaking, several commenters on the PEL for silica focused on two issues: (1) The adequacy of the proposed 0.1-mg/m³ respirable quartz limit in reducing the risk of silicosis; and (2) recent evidence describing the potential carcinogenicity of silica dust.

With regard to the first issue, available data do not appear to be adequate to determine a no-effect level for crystalline quartz. For example, Dr. John Peters, the author of the chapter on silica in the 1986 NIOSH reference on respiratory diseases, concluded as follows:

All of the studies described in this section provide evidence for adverse pulmonary effects at levels of exposure above 10 mppcf or 0.1 mg/m³. Some showed that foundry workers exposed to the equivalent of 0.05 mg/m³ of quartz developed silicosis while those with less exposure did not * * *. All the Vermont findings were seen with an average exposure of around 0.05 mg/m³ of quartz. It is possible, however, that since this was the average exposure, individuals whose exposure exceeded this level accounted for the noted effects. (The "no effect" level was probably below 0.05 mg/m³, but the available data did not allow accurate determinations.) (Peters, J.M., "Silicosis." In: Occupational Respiratory Diseases, p. 229, J.S. Merchant, ed. DHHS (NIOSH) Pub. No. 86–102, NIOSH 1986b).

OSHA agrees with Dr. Peters that the available data are not adequate for the purpose of establishing a NOEL for this substance and is therefore proposing at this time a 0.1 mg/m³ PEL that will ensure consistency in the limit across all

OSHA-regulated sectors. As discussed below, OSHA expects to consider silica's potential toxicity in detail in the first update proceeding, and the appropriateness of the PEL will be evaluated at that time.

The second major issue raised by participants in the prior air contaminants rulemaking concerned silica's carcinogenicity. There is considerable evidence that silica is carcinogenic both in animals and humans. For example, silica has caused tumors of many kinds at various sites (site-of-contact tumors and tumors of the lungs, liver, gastrointestinal tract, kidneys, and bronchi) in three species of animal (rats, mice, and hamsters) and by six routes of exposure (inhalation, intraperitoneal, intrapleural, intravenous, intratracheal, and implanted under the skin) (RTECS 1991; IARC 1987, Vol. 42; IARC 1987, Suppl. 7).

The International Agency for Research on Cancer characterizes the evidence for the carcinogenicity of silica in animals as sufficient and summarizes its findings as follows:

Various forms and preparations of crystalline silica produced adenocarcinomas and squamous-cell carcinomas of the lung in rats after inhalation or repeated intratracheal instillation. Thoracic and abdominal malignant lymphomas developed in rats after single intrapleural and intraperitoneal injections of suspensions of several types of quartz. Malignant lymphomas developed after intrapleural injection of cristobalite and tridymite. No tumorigenic response was observed in hamsters after repeated intratracheal instillation of quartz dusts or in a mouse-lung adenoma assay with one sample of quartz.

In addition to these findings in animals, IARC summarized the epidemiologic studies of workers exposed silica in a variety of occupational settings as follows:

A number of studies have shown that persons diagnosed as having silicosis after occupational exposure to dust containing crystalline silica have an increased risk for dying from lung cancer. This increase has been seen among miners, quarry workers, foundry workers, ceramic workers, granite workers and stone cutters.

Workers in the granite industry have shown increased risks for lung cancer in some studies; the excesses were of the order of 10–30% and were not usually statistically significant. An extended follow-up of Finnish granite workers showed 22 lung cancer cases, with 17.1 expected. When allowing for a latency of 15 years, 21 cases were observed, whereas nine were expected (p<0.01; Poisson distribution). Smoking habits were similar to those of the active Finnish male population, and exposures to radon and asbestos were considered unlikely to have occurred. A recent joint Nordic register linkage study, combining lung cancer

mortality and incidence data from the cancer registries with census-based records on previous occupation of 20-64-year-old males, showed an elevated risk of lung cancer among stone cutters in Finland and Denmark, but not in Sweden or Norway. Excess risk was also seen for Finnish males in excavation work, whereas no such risk was evident in the other countries.

Three epidemiological studies of workers in the ceramics, glass and refractory brick industries, using different designs, have shown a roughly two-fold increase in mortality from lung cancer. Only one case-referent study took smoking into account. The Nordic register study also found an excess of lung cancer for Danish glass-workers, but workers in the ceramics industry did not have an elevated risk in any of the other countries. A U.S. cohort study of pottery workers exposed to silica and talc showed a nonsignificant standardized mortality ratio of 137 for workers exposed to high levels of silica dust with no talc exposure.

Several studies of metal miners have shown mortality rates from lung cancer some 20–50% higher than expected. In the Nordic register study, relative risks from 1.0 (Norwegian metal miners) to 5.0 (Finnish nonferrous ore miners) were seen. The largest group was Swedish iron ore miners; their relative risk was 3.2 (95% confidence interval, 2.9–3.5), based on 124 observed cases. However, in repeated cohort studies of workers in a gold mine, no excess lung cancer risk was seen. The contribution of radon has not in general been assessed.

Coal miners appear not to be at increased

risk of lung cancer.

Epidemiological studies of both exposed populations and silicotics give indications of the carcinogenicity of a working environment contaminated with crystalline silica, particularly in combination with other exposures. In most industries studied, such an effect cannot be separated from those of other concomitant carcinogenic exposures, but in the granite and stone industry the exposure to silica is fairly pure. Few studies provide data on smoking. It is not clear whether the mechanisms of a possible carcinogenic effect of crystalline silica requires a fibrotic process.

Based on a review of the human and animal evidence for the carcinogenicity of crystalline silica, the International Agency for Research on Cancer has assigned this substance a Group 2A (probably carcinogenic to humans) classification. (OSHA notes that IARC's findings apply to all of the crystalline forms of silica, including quartz, cristobalite, tridymite, tripoli, and fused silica.)

Because OSHA believes that the primary objective of the present rulemaking in construction, maritime, and agriculture should be the promulgation of consistent PELs in all OSHA-regulated sectors, the Agency is not at this time initiating a full 6(b) rulemaking on crystalline silica but is postponing a comprehensive review of silica's cancer-causing potential until

the first PEL update. At present, OSHA believes that it is appropriate to propose an 8-hour TWA PEL of 0.1 mg/m3 for quartz, measured as the respirable silica fraction, in construction, maritime, and agriculture. This limit represents no substantial change in value from OSHA's current formula limit for this substance in construction and maritime, but will simplify employee sampling procedures in these sectors. With regard to the agricultural sector, OSHA preliminarily concludes that, in the absence of a limit, exposure to respirable quartz dust presents a significant risk of silicosis, and perhaps of cancer, to workers. As OSHA's Preliminary Regulatory Impact Analysis for the agricultural sector shows, many agricultural workers are potentially exposed to silica in the course of their work. OSHA believes that promulgation of the 0.1 mg/m3 limit will substantially reduce this risk for these workers. In addition, promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated

SILICA, CRYSTALLINE QUARTZ (TOTAL DUST)

CAS: 14808–60–7; Chemical Formula: SiO₂

H.S. No. 2142

The current OSHA limit for silicacontaining dusts (measured as total dust) in construction and maritime is expressed as mppcf and derives from the following formula: 250/%SiO2+5. There is no PEL in agriculture. NIOSH has no REL for silica measured as total dust; the ACGIH TLV*-TWA is 0.3 mg/ m3. OSHA is proposing an 8-hour TWA PEL of 0.3 mg/m3 for crystalline quartz (total dust) in agriculture and is additionally expressing the PEL for this substance in mg/m3 rather than as a formula to simplify exposure monitoring. This action would make OSHA's PEL for crystalline quartz (total dust) consistent across all regulated sectors.

Crystalline quartz occurs naturally in certain types of soil (e.g., in sandy soil) and can also be produced by heating amorphous or other types of silica to high temperatures. Crystalline silica consists of colorless crystals and is used or liberated in the manufacture of glass, porcelain, and pottery, in metal casting, sandblasting, and granite cutting, and in the production of refractory, grinding, and scouring compounds (Clayton and Clayton 1981, p. 3020; Proctor, Hughes, and Fischman 1988, p. 440). Agricultural workers are often exposed to silica when they till silicaceous soil.

Silica exposure causes a chronic and disabling pulmonary disease, called silicosis, and may cause cancer in exposed workers. The animal and human studies describing silica's toxicity do not generally differentiate between total dust and the respirable fraction (i.e., do not identify the particle size of the particulate causing the effect). It is therefore difficult to determine which studies relate to total dust and which involve the respirable particulate. However, there is general agreement that particle size is the principal factor affecting silica's toxic potential (Merchant 1986). Accordingly, OSHA is proposing a less stringent limit for crystalline quartz (total dust) than for crystalline quartz (respirable fraction); the proposed PELs for these substances are 0.1 mg/m3 and 0.3 mg/ m3, respectively. The toxicology writeup for crystalline silica appears in this preamble under the entry for Crystalline silica-quartz (respirable)" and the reader is referred to that section for the details of silica's toxicity in

animals and humans. Based on the voluminous evidence of crystalline silica's toxicity, OSHA preliminarily concludes that the proposed 8-hour TWA PEL of 0.3 mg/m3 is necessary in agriculture to protect workers in this sector from the significant risk of silicosis and other diseases, including cancer, potentially associated with exposure to crystalline quartz (total dust). The Agency considers these diseases to be material impairments of health and preliminarily concludes that the proposed PEL will substantially reduce these risks. Furthermore, OSHA believes it appropriate to propose an 8-hour TWA PEL of 0.3 mg/ms for quartz, measured as total dust, for construction and maritime. This limit represents no substantial change from OSHA's current formula limit for these sectors, but will simplify employee sampling procedures. Promulgation of this limit will also make the PEL for crystalline silica, quartz (total dust) consistent across all OSHAregulated sectors.

SILICA, CRYSTALLINE—TRIDYMITE CAS: 15468-32-3; Chemical Formula: SiO2

H.S. No. 1356

OSHA's PEL for tridymite in the construction and maritime industries is expressed as the formula 250/%SiO2+5. There is no limit in agriculture. The ACGIH recommends an 8-hour TWA limit of 0.05 mg/m3, measured as silica dust. The ACGIH limit is based on a study conducted by King, Mohanty Harrison, and Nagelschmidt (1953/Ex. 1-85) that found tridymite to be the most active of the free silica forms when injected intratracheally into rats. NIOSH

has a REL for this substance of 0.05 mg/ m3 as a 10-hour TWA. The Agency is retaining its PEL for tridymite in construction and maritime but is now expressing this limit in mg/m3 rather than as the formula; the proposed limit is 0.05 mg/m3, and OSHA is also proposing to extend this limit to agriculture. An 8-hour TWA limit of 0.05 mg/m3 was recently established for tridymite in general industry: promulgation of the proposed 0.05 mg/ m3 limit in construction, maritime, and agriculture will thus make OSHA's PEL for tridymite consistent across all regulated sectors.

Tridymite is a transparent, tasteless form of free silica. Tridymite is used as a filtering and insulating medium and as a silicaceous refractory material for furnace linings and silica bricks (Clayton and Clayton 1981, p. 3020). Tridymite is one of the crystalline polymorphs of silica; accordingly, the toxicology writeup that appears in this preamble under the heading for "Crystalline silica quartz (respirable)" also applies to tridymite, and the reader is referred to that section for the details of silica's toxicity in humans and animals.

Although expressed in different units, OSHA's current and proposed limits for tridymite in construction and maritime are comparable. The mg/m3 limit is being proposed merely to simplify the monitoring of tridymite dust concentrations. OSHA is proposing to replace its current formula limit for tridymite in construction and maritime with a numerically equivalent 8-hour TWA limit of 0.05 mg/m3, measured as respirable silica dust, and to extend this limit to agriculture. OSHA is proposing this change to simplify employee exposure monitoring in the construction and maritime industries, and to substantially reduce the significant risk of tridymite-induced silicosis and possible cancer that exists in the agricultural sector in the absence of a limit for this substance.

SILICA, CRYSTALLINE—TRIPOLI CAS: 1317-95-9; Chemical Formula: SiO2 H.S. No. 1357

Although OSHA's Table Z-2, which is presently in effect in construction and maritime, does not specifically indicate a limit for tripoli, OSHA's current limit for crystalline quartz (which applies to tripoli) is expressed as mppcf and derives from the formula:

%SiO2+5

*The percentage of crystalline silica in the formula is the amount determined from airborne samples, except in those cases in

which other methods have been shown to be applicable.

The 8-hour TLV®-TWA ACGIH limit for tripoli is 0.1 mg/m3, measured as respirable silica dust. NIOSH has a REL of 50 µg/m3 as a TWA for tripoli. OSHA is proposing an 8-hour TWA PEL of 0.1 mg/m3 for tripoli in the construction, maritime, and agriculture sectors. This is the limit recently established for tripoli in general industry.

Tripoli is a colorless, microcrystalline polymorph of silica. It is used in buffing compounds, on buffing wheels, in scouring soaps, powders, and polishes, and for polishing optical lenses (Clayton and Clayton 1981, p. 3020). Because tripoli is a crystalline form of silica, the toxicology writeup that appears in this preamble under the heading for "Crystalline silica quartz (respirable)" also pertains to tripoli.

In construction and maritime, OSHA is proposing to replace its limit for tripoli, which is expressed as the formula presented above, with a comparable 8-hour TWA limit of 0.1 mg/ m3, measured as respirable silica dust; the Agency is also proposing to extend this limit to agriculture to reduce the significant risk of tripoli-induced silicosis and possible cancer among workers in this sector. Promulgation of this limit will make the PEL for tripoli consistent across all OSHA-regulated

SILICA, FUSED CAS: 60676-86-0: Chemical Formula: SiO₂ H.S. No. 1358

Fused silica is a crystalline form of quartz. As such, it is currently covered in construction and maritime by OSHA's PEL for quartz. OSHA's current limit for quartz dust in construction and maritime operations is the formula 250/%SiO2+5, measured as mppcf; there is no PEL in agriculture, and NIOSH has no REL. The ACGIH has an 8-hour TLV®-TWA limit of 0.1 mg/m3, measured as free silica; the ACGIH adopted this limit in 1985 to simplify the monitoring of quartz dust concentrations. OSHA is proposing a 0.1 mg/m3 8-hour TWA PEL for fused silica in construction, maritime, and agricultural operations. The limit being proposed for construction, maritime, and agriculture was recently established for fused silica in general industry.

Fused silica is a colorless, odorless, noncombustible solid that is employed in the aerospace industry as an ablative material in rockets and spacecraft. Fused silica can also be used in making camera lenses and finds use in fiber form as a reinforcer of plastics (ACGIH 1986, p. 521).

In construction and maritime, OSHA is replacing its current limit for fused silica, which is expressed as the formula presented above, with a comparable 8hour TWA PEL of 0.1 mg/m3, measured as respirable silica dust; the Agency is also proposing to extend this limit to agriculture to reduce the significant risk of silicosis and possible cancer that exists in the absence of a limit for fused silica in this sector. OSHA believes that this limit will also simplify employee exposure monitoring in construction and maritime. In addition, promulgation of this limit will make OSHA's PEL for fused silica consistent across all regulated sectors. Because fused silica is a crystalline form of silica, the toxicology writeup that appears in this preamble under the heading for 'Crystalline silica quartz (respirable)" also applies to fused silica.

SOAPSTONE, TOTAL DUST SOAPSTONE, RESPIRABLE DUST CAS: None; Chemical Formula: 3 MgO-4 SiO₂-H₂O

H.S. No. 1363 (total dust) H.S. No. 1363A (respirable dust)

OSHA's current exposure limit for soapstone, total dust, in construction and maritime operations is 20 mppcf [6 mg/m3); the Agency has no separate limit for the respirable fraction. There is no limit in agriculture. The ACGIH has established individual TLV*-TWAs for two forms of soapstone: 6 mg/m3 for total dust and 3 mg/m3 for the respirable fraction, both measured as total dust or respirable dust containing less then 1 percent quartz. Because the ratio of total dust mass to the mass of the respirable fraction is 2:1 (ACGIH 1984, p. 480), the 6 mg/m3 total dust limit automatically implies a 3 mg/m3 limit for the respirable fraction. NIOSH has no REL for soapstone. OSHA is proposing permissible exposure limits of 6 mg/m3 as an 8-hour TWA (total dust) and 3 mg/m3 as an 8-hour TWA (respirable dust) for soapstone in construction, maritime, and agriculture. NIOSH (Ex. 8-47, Table N1) concurred with these limits when the Agency recently established them in general industry.

A study by Dreessen and DallaValle (1935/Ex. 1–588) of mill workers exposed to soapstone showed lung changes in these workers, but it is believed that the dusts involved in these exposures were actually composed of steatite talc, which had a tremolite content of 10 percent. Experiments by Miller and Sayers (1941/Ex. 1–595) showed no measurable toxic effects in guinea pigs injected intraperitoneally with various samples of soapstone.

In construction and maritime, OSHA is proposing to express its limit for soapstone (total dust) in mg/m3, rather than mppcf, to simplify employee sampling and analysis. The total dust limit being proposed for the construction and maritime industries is an 8-hour TWA of 6 mg/m³, which is equivalent to the current limit of 20 mppcf, and the new limit of 3 mg/m3 for respirable dust has been implicit in the existing total dust limit. In agriculture, OSHA is proposing both limits to reduce the risk of tremolite-induced pulmonary effects in exposed workers. Promulgation of these limits will also make OSHA's PELs for this substance consistent across all regulated sectors. SULFUR DIOXIDE

CAS: 7446-09-5; Chemical formula: SO₂ H.S. No. 1375

OSHA's current limit for sulfur dioxide (SO2) in the construction and maritime industries is 5 ppm as an 8hour TWA. There is no limit in agriculture. The Agency is proposing to revise this limit to 2 ppm as an 8-hour TWA, to add a 5 ppm STEL, and to extend these limits to agriculture. Although NIOSH recommends a limit of 0.5 ppm for sulfur dioxide, NIOSH did concur (Ex. 8-47, Table N1) with OSHA's proposed limits when the Agency established them recently in general industry. The ACGIH has a TLV*-TWA of 2 ppm and a TLV*-STEL of 5 ppm for sulfur dioxide. Promulgation of the proposed limits will make the PELs for this substance consistent across all OSHA-regulated sectors.

Sulfur dioxide is a colorless, nonflammable gas or liquid with a suffocating odor. It is used in treating wood pulp for paper manufacturing, in ore and metal refining, and in the extraction of lubricating oils; as a bleaching, disinfecting, and fumigating agent; as a food additive and preservative; and as a reducing agent (ACGIH 1986, p. 542 (87)). Sulfur dioxide is generated as an unwanted byproduct of combustion, and especially during the burning of coal or heavy oil. When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Workplace exposure to sulfur dioxide causes both acute and chronic effects. The chronic effects of exposure include permanent pulmonary impairment, which is caused by repeated episodes of bronchoconstriction. A number of human and animal studies demonstrate this effect (Skalpe 1964/Ex. 1–438; Smith, Peters, Reading, and Castle 1977/Ex. 1–

805; Archer and Gillam 1978/Ex. 1–711; Ministry of Health (Canada) 1976/Ex. 1– 1208; Lewis, Campbell, and Vaughan 1969, as cited in ACGIH 1986/Ex. 1–3, p. 542).

In a study of Norwegian paper pulp mill workers, Skalpe (1964/Ex. 1–438) reported that average SO₂ concentrations were believed to range from 2 to 36 ppm. Results showed a significantly higher frequency of respiratory disease symptoms, including coughing, expectoration, and dyspnea, among workers less than 50 years of age (i.e., those with the shortest exposure). Workers older than 50, however, did not display symptomatology different from that of controls.

More recently, Smith, Peters, Reading, and Castle (1977/Ex. 1-805) studied a group of smelter workers exposed, on average, to less than 2 ppm SO2 but concurrently exposed to respirable particulate at levels generally less than 2 mg/m3. These workers showed a decrement in forced vital capacity (FVC) and forced expiratory volume (FEV1) of 4.8 percent when compared with controls. These authors concluded that workers exposed to SO2 levels above 1 ppm had an accelerated loss of pulmonary function. This study has been criticized on the grounds that the control population itself may have been exposed to respiratory toxins and that other contaminants, such as iron sulfites, may have contributed to the pulmonary decrement seen in these smelter workers. (OSHA notes that the first criticism would lead to an underestimate of the severity of the health effects.) On average, 60 percent more of the workers exposed to concentrations of SO2 greater than 1 ppm reported symptoms of chronic cough than did workers who were exposed to SO2 at a concentration below 1 ppm. The prevalence of chronic sputum production was elevated for workers who had never smoked and who were exposed above 1 ppm.

Archer and Gillam (1978/Ex. 1-711) studied workers at the same smelter facility and obtained results similar to those of Smith, Peters, Reading, and Castle (1977/Ex. 1-805). Significant reductions in FVC and FEV, were found to be associated with chronic exposures to 0.4 to 3 ppm SO2 (TWA) with concomitant exposure to particulate. These authors also found a corresponding increase in some symptoms of respiratory disease (chronic bronchitis) that was not attributable to smoking. Tomono and coworkers (1961, as cited in ACGIH 1986/Ex. 1-3, p. 542) found that 1.6 ppm was the lowest concentration that

produced bronchoconstriction in 46

healthy male subjects.

NIOSH recommends a 0.5-ppm 8-hour TWA limit for SO2. In addition to the studies by Archer and Gillam (1977/Ex. 1-711) and Smith, Peters, Reading, and Castle (1977/Ex. 1-805) described above, NIOSH relied on a third study (Ministry of Health (Canada) 1976/Ex. 1-1208) of smelter workers exposed to SO2 levels of 2.5 ppm for 10 or more years, which showed an increased incidence of respiratory disease in these workers. A fourth study cited by NIOSH (NIOSH 1977m. as cited in ACGIH 1986/Ex. 1-3, p. 542) reported that 10,000 workers exposed to SO2 at levels of 0.35 ppm showed no adverse exposure-related

Alarie and co-workers (1970 and 1972, as cited in ACGIH 1986/Ex. 1-3, p. 542) found that guinea pigs exposed to SO2 by inhalation showed no decrement in pulmonary function at SO2 levels of 5 ppm; monkeys exposed to 1.3 ppm for 78 weeks also showed no deficit (Alarie, Ulrich, Busey et al. 1970 and 1972, both as cited in ACGIH 1986/Ex. 1-3, p. 542). However, in another study, dogs exposed continuously to 5 ppm for 225 days showed increased pulmonary flow resistance and a decrease in lung compliance (Lewis, Campbell, and Vaughan 1969, as cited in ACGIH 1986/ Ex. 1-3, p. 542). In addition, rats exposed to 10 ppm SO2 daily for six weeks developed a thickening of the mucous layer that interfered with effective particle clearance (Dalhamn 1956, as cited in ACGIH 1986/Ex. 1-3, p. 542).

The acute effects of SO2 exposure have been recognized for years in industrial settings; symptoms of acute overexposure include upper respiratory tract irritation, rhinorrhea, choking, and coughing. These symptoms are so disagreeable that most persons will not tolerate exposure for longer than 15minutes. Within 5 to 15 minutes of the onset of exposure, workers develop temporary reflex bronchoconstriction and increased airway resistance. Shortterm exposure causes measurable bronchoconstriction (Frank, Amdur, Worcester, and Whittenburger 1962, as cited in ACGIH 1986/Ex. 1-3, p. 542; Weir, Stevens, and Bromberg 1972/Ex. 1-401); the ACGIH (1986/Ex. 1-3, p. 542) reports that this bronchoconstriction is dose-related and is manifested as an increase in pulmonary flow resistance.

These acute effects, which may be severe, indicate the need for the 5 ppm STEL. (The Immediately Dangerous to Life or Health (IDLH) level for SO₂ is 100 ppm.) With a 2 ppm 8-hour TWA alone, a worker could be exposed to 100 ppm for 10 minutes or to 30 ppm (the concentration that produces severe

respiratory symptoms (Kehoe Ex. 1–339; Skalpes Ex. 1–438)) for 20 minutes. The 15-minute 5 ppm STEL is thus necessary to prevent these effects as well as the bronchoconstriction that can develop in sensitive individuals from brief exposure to relatively low levels of SO₂. Acute bronchoconstrictive effects are precisely the kinds of effect STELs were designed to protect against.

Efforts have been made to quantify the acute no-adverse-effect level for SO2-induced increased airway resistance. Frank, Amdur, Worcester, and Whittenberger (1962, as cited in ACGIH 1986/Ex. 1-3, p. 542) reported that, at SO2 concentrations of 1 ppm, 1 in 11 healthy subjects developed pulmonary flow resistance; at concentrations of 5 or 13 ppm, there was a 39- and 72-percent increase, respectively, in such resistance. Weir, Stevens, and Bromberg (1972/Ex. 1-401) noted a statistically significant but reversible increase in small-airway resistance and a decrease in lung compliance at a concentration of 3 ppm; however, Burton et al. (1969) reported no effects, even among smokers, at a level

N.R. Frank, Professor of Medicine at the University of Washington State, commented during the 1977 hearing (NIOSH 1977m) that sulfur dioxide may not by itself be hazardous to the lungs but that an aerosol of sulfur dioxide and water or SO₂ oxidized to sulfate particulate may increase the toxic potential of SO₂ (Ex. 40, Docket H–039). Dr. Frank also presented evidence showing that a single short-term exposure to very high SO₂ levels (200 to 1000 ppm) can produce lung damage (Ex.

40, Docket H-039).

The lack of chronic effects observed in animals at levels below 5 ppm (Alarie, Ulrich, Busey et al. 1970 and 1972, as cited in ACGIH 1986/Ex. 1-3, p.-542) caused commenters to question whether chronic lung disease results from long-term exposure to SO2 below the current 5 ppm PEL. Dr. Alarie appeared at the 1977 hearing and testified on animal studies conducted by him and others on sulfur dioxide (NIOSH 1977m, as cited in ACGIH 1986/ Ex. 1-3, p. 542). He testified that, in his opinion, the long-term studies in animals support the establishment of a ceiling value for SO2 but do not indicate that benefits would be gained by reducing the time-weighted average from 5 to 2 ppm. OSHA agrees with Dr. Alarie that a STEL is necessary to minimize high short-term exposures to SO2; however, OSHA does not agree that no effects have been seen in animals at levels at or below 5 ppm. For example, Lewis, Campbell, and Vaughan (1969, as cited

in ACGIH 1986/Ex. 1-3, p. 542) showed that beagles exposed to 5 ppm SO₂ exhibited decreased dynamic compliance and increased flow resistance. In addition, NIOSH (1974b/Ex. 1-235) has reported:

[M]an is considered to be more sensitive than other mammals to the effects of sulfur dioxide in ranges commonly employed experimentally * * * (Ex. 1–235).

It is therefore not surprising that humans have also been shown to develop respiratory effects, including bronchoconstriction, coughing, and sputum production, at levels below 5 ppm (Smith, Peters, Reading, and Castle 1977/Ex. 1–805; Archer and Gillam 1978/Ex. 1–711; Frank, Amdur, Worcester, and Whittenburger 1962, as cited in ACGIH 1986/Ex. 1–3, p. 542; Weir, Stevens, and Bromburg 1972/Ex. 1–401).

In the prior rulemaking for general industry, several commenters (Exs. 3-1123, 8-57, 86, 86A, 117, 177, and 188) argued that the Ferris et al. study demonstrated a lack of chronic effects caused by exposure to pure SO2. OSHA disagrees. First, the Ferris et al. study shows deleterious health effects at SO2 levels down to 3 ppm that become progressively worse at 5 ppm. Second, other studies show adverse health effects in animals exposed to pure SO2 at levels of 5 ppm. Third, SO2 causes bronchoconstriction. OSHA therefore believes that a 2 ppm TWA is necessary to protect workers in construction, maritime, and agriculture from these significant risks, which are associated either with exposure to pure SO2 or to SO2 and particulates.

Commenters cited Rom et al. (1983) to the effect that pulmonary function does not decline as a result of exposure to SO₂. In 1983, Rom et al. conducted a follow-up study of Smith et al.'s cohort (which was studied originally in 1974). Rom et al. reported a statistically significant improvement in pulmonary function in workers in two of the groups expected to show the greatest decline. For the period 1980 to 1983, the mean annual changes across both groups were negative.

The investigator's explanation for the apparent increase in FVC in the 1973–1980 period is that the pulmonary function tests given by Smith et al. in 1973 were inadequate. However, they also suggest that the use of a more reliable dual-cartridge respirator in the new smelter may have reduced exposure to SO₂, leading to improved pulmonary function. Furthermore, the size of the study is quite small, especially once the cohort is stratified into smokers, ex-smokers, and

nonsmokers. Thus, the small size of this study may have made it difficult to observe any significant SO₂-related declines in pulmonary function.

A study by Holness et al. (1985) examined the change in pulmonary function in a group of nickel refinery workers both before and after shutdown of the smelter. Average SO2 concentration in the smelter was 0.47 ppm. Pulmonary function was assessed twice during a workweek and again following a 6-month shutdown period during which no exposures to SO2 or particulate occurred. Pulmonary function exams conducted on Monday showed that, after adjusting lung function values for the effects of smoking, smelter workers had significantly lower FVC and FEV values than office workers. On Thursday, smelter workers exhibited further declines in FVC and FEV1, although the magnitude of the change in FEV1 was not statistically significant. Area sampling for SO2 and particulate suggested a direct relationship between the change in FVC and FEV, and exposure to SO2 and particulate. In addition, the prevalence of respiratory symptoms (adjusted for smoking) was significantly higher among these smelter workers than office workers both prior to and after the shutdown period.

Taken together, the evidence from all of the studies described in this subsection clearly shows that exposure to SO2 below 5 ppm (both in the pure state and together with particulates) does cause respiratory symptoms. including repeated episodes of bronchoconstriction. The studies by Smith, Peters, Reading, and Castle (1977/Ex. 1-373), Archer and Gillam (1978/Ex. 1-711), and Frank, Amdur, Worcester, and Whittenberger [1962, as cited in ACGIH 1986/Ex. 1-3, p. 542) consistently demonstrate that persons exposed to concentrations of SO2 below 5 ppm have an accelerated loss of pulmonary function and exhibit adverse pulmonary symptoms, both acute and chronic. OSHA believes that these effects constitute material impairments of health and are significant.

The second point raised by commenters concerned the formation of other toxic and irritating products from the interaction between SO₂ and water or between SO₂ and particles. Some of the participants in the earlier rulemaking, such as Dr. Colucci of the Corn Refiners Association, testified that it would be more protective to identify and limit exposure to each of these byproducts, rather than to regulate SO₂ alone. OSHA disagrees with this approach; since these products are all

formed from sulfur dioxide, limiting exposure to SO2 will concurrently limit exposure to these SO2 by-products. This approach is more straightforward and easier to implement than attempting to identify the myriad decay products that may be formed in different industrial settings. Furthermore, the studies discussed above clearly establish a relationship between airborne SO2 levels and adverse effects; no quantitative relationship on which to base a PEL has been established for the decay products of SO2 reactions. Therefore, to reduce the significant risk of respiratory symptoms among exposed workers, OSHA finds that limiting exposure to SO2 will be effective.

After considering all of the relevant evidence from both the 1977 and the present dockets, OSHA preliminarily concludes that an 8-hour TWA PEL of 2 ppm and a STEL of 5 ppm are necessary to reduce the significant risk of adverse respiratory effects that have been demonstrated to occur in workers exposed to SO2 above these levels. The Agency believes that the coughing, increase in sputum production, bronchoconstriction, and significant declines in pulmonary function observed in workers exposed to SO2 at the levels permitted by the current limit constitute material impairments of health and functional capacity, and must be protected against. Accordingly, OSHA is proposing these PELs for workers in construction, maritime, and agricultural workplaces. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

SULFUR TETRAFLUORIDE CAS: 7783-60-0; Chemical Formula: SF₄ H.S. No. 1378

OSHA has no exposure limit for sulfur tetrafluoride in the construction, maritime, or agriculture industry. The ACGIH has a limit of 0.1 ppm as a ceiling; NIOSH has no REL for this substance. OSHA is proposing a PEL of 0.1 ppm as a ceiling; NIOSH (Ex. 8–47, Table N1) concurred with this limit when the Agency recently established it in general industry. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Sulfur tetrafluoride is a colorless, noncombustible gas. It is used as a fluorinating agent in the production of water and oil repellents and lubricity improvers. Sulfur tetrafluoride is also used in making pesticides (Hawley's 1987, p. 1109; New Jersey Fact Sheet 1986, p. 1).

On contact with moisture, sulfur tetrafluoride produces sulfur dioxide

and hydrogen fluoride (HF) (Lester 1971, as cited in ACGIH 1986/Ex. 1-3, p. 546), and it is the release of HF that is primarily responsible for sulfur tetrafluoride's toxic effects (Zapp 1971, as cited in ACGIH 1986/Ex. 1-3, p. 546). A du Pont study [1961, as cited in ACGIH 1986/Ex. 1-3, p. 546) of rats exposed for four hours to 4 ppm sulfur tetrafluoride over a period of 10-days reported that the animals demonstrated nasal discharge, difficulty in breathing, and weakness. Autopsies of these animals revealed evidence of emphysema, but those rats surviving exposure and given a two-week rest period after exposure showed no significant pathological changes. In the same study by du Pont (1961, as cited in ACGIH 1986/Ex. 1-3, p. 546), a four-hour exposure to 20 ppm sulfur tetrafluoride proved lethal to one of two rats. In a study by Clayton (1962/Ex. 1-409), irregular breathing and signs of irritation were observed following exposures to concentrations of 20 ppm and lower; animals receiving lethal amounts of sulfur tetrafluoride showed pulmonary edema on autopsy, and those with sublethal exposures demonstrated no pathologic changes 14 days later.

OSHA is proposing a 0.1-ppm ceiling limit for this highly toxic gas in the construction, maritime, and agriculture industries. The Agency believes that establishing this limit for this previously unregulated chemical will reduce the significant risk of chronic respiratory effects potentially associated with exposure to sulfur tetrafluoride at the levels permitted in these sectors by the absence of any OSHA limit. OSHA considers the chronic respiratory effects caused by exposure to sulfur tetrafluoride to be material impairments of health. In addition, promulgation of this limit will make the PEL for this substance consistent across all OSHAregulated sectors.

TALC (Containing no asbestos)
CAS: 14807-96-6; Chemical Formula:
Mg₃Si₄O₁₀(OH)₂
H.S. No. 1381

The current OSHA PEL for nonasbestiform talc (containing less than 1 percent crystalline silica) in the construction and maritime industries is 20 million particles per cubic foot of air (mppcf) as an 8-hour TWA; when expressed as mg/m³, this is comparable to 3 mg/m³. There is no limit in agriculture. The ACGIH has a TLV*–TWA of 2 mg/m³ (15 mppcf) for talc, measured as respirable dust, and this is the limit being proposed by OSHA for construction, maritime, and agriculture operations. NIOSH has no REL for this

substance, but concurred (Ex. 8-47, Table N1) that this limit was appropriate when the Agency established it in

general industry.

Talc is a fine powder that is white to gray-white in color; it is found as a mineral, and the main component is a crystalline hydrated silicate of magnesium that is usually in the form of plates but occasionally may be in the form of fibers. Talc is used in industrial products and cosmetics. Talc is also used in insecticides, ceramics, paints, paper, plastics, rubber, and roofing (ACGIH 1986, p. 550).

The health-effects evidence for talc is complicated by the fact that talcs contain amphiboles and other minerals, in addition to platiform talc crystals; adverse health effects appear to be related to the nonplatiform content (that is, to the fiber content) of the talc in question (ACGIH 1986/Ex. 1-3, p. 550). There are conflicting views regarding the extent to which the fibrous constituents are asbestos; however, no health effects information is available that is specifically related to fibrous talc

(ACGIH 1986/Ex. 1-3, p. 550)

Numerous epidemiological studies have documented the effects on workers of long-term exposures to talc. In 1942, Porro et al. (1942, as cited in Stokinger 1981b/Ex. 1-1127) published a report in which 15 cases of talc pneumoconiosis, including five postmortem examinations. showed that asbestotic bodies were almost always present in fibrotic areas of the lungs of those workers with talcosis. Siegal and colleagues (1943, as cited in Stokinger 1981b/Ex. 1-1127) noted that the incidence of advanced fibrosis in a group of 221 talc miners and millers was 14.5 percent. These workers were primarily exposed to fibrous talc, which was believed to be responsible for the pathology of the asbestos-like lung lesions. A study by McLaughlin et al. (1949, as cited in Stokinger 1981b/Ex. 1-1127) revealed that talc-induced pneumoconiosis was caused by the fibrous varieties of talc; in animal studies by Schepers and Durkan (1955, as cited in Stokinger 1981b/Ex. 1-1127), the degree of fibrosis in the lung tissue was found to be a function of the length of the talc fibers, rather than of the composition of the talc itself. A paper by Kleinfeld, Giel, Majeranowski, and Messite (1963, as cited in Stokinger 1981b/Ex. 1-1127) reported that postmortem examinations on six talc industry workers showed that the asbestotic bodies found in the lung bronchioles or embedded in fibrous tissue were indistinguishable from the asbestos bodies seen in cases of asbestosis.

Kleinfeld, Messite, Kooyman, and Zaki (1967/Ex. 1-704) later conducted a cohort study of 220 workers who had been employed in a mine that produced talc that had a tremolite and anthophyllite content. Of the 91 deaths in this group, 10 resulted from respiratory cancer and 28 were attributed to pneumoconiosis. The proportional mortality rate from respiratory cancer was four times the expected rate. In 1974, when Kleinfeld, Messite, and Zaki (Ex. 1-705) performed a follow-up study of this group (which at that time consisted of 260 workers [108 deaths]), they found significant differences between the expected and observed mortality in the period 1950 to 1954, but not during 1960 to 1969. These investigators attributed this finding to the reduction in talc dust counts from averages of 25 to 73 mppcf (approximately 4 to 12 mg/m3) in the years between 1948 and 1965 to averages of 9 to 43 mppcf (approximately 1.5 to 6.5 mg/m3) in the period 1966 to 1969. This study also showed a decrease of greater than 50 percent in deaths due to pneumoconiosis in the 1965-to-1969 time period.

Studies by NIOSH (Dement and Zumwald 1978, as cited in ACGIH 1986/ Ex. 1-3, p. 552) of 398 white male workers employed between 1947 and 1959 in the talc industries found that 74 of these men had died, and that bronchogenic cancer was the cause of death in nine men; only 3.3 deaths from this cause would have been expected. Nonmalignant respiratory disease (NMRD) exclusive of influenza, pneumonia, and tuberculosis accounted for three deaths: 1.5 would have been expected. From these data, NIOSH concluded that a significant increase in mortality due to bronchogenic cancer and NMRD had occurred as a result of occupational exposure to talc dust. NIOSH's report also included a morbidity study of 12 talc industry workers, currently employed, in which chest x-rays, lung function tests, and questionnaires were used. This study concluded that a higher prevalence of cough, phlegm, dyspnea, and irregular opacities in chest x-rays existed in these workers than in potash miners; instances of pleural thickening and calcification were greater than in coal and potash miners; and the pulmonary function of talc workers overall was reduced in comparison with that of coal and potash miners employed for the same length of time. The reductions in pulmonary function among the talc workers were dose- and durationrelated.

The ACGIH (1986/Ex. 1-3, p. 552) concluded that serious health effects have been associated in the past (i.e., prior to 1945) with exposures to amphibole-containing talc. However, the ACGIH believes that the introduction of mining improvements has all but eliminated "the excess of death rates from pneumoconiosis and lung cancer" (ACGIH 1986/Ex. 1-3, p. 552).

Two recent studies of the health effects associated with talc exposures (Rubino, Scansetti, Piolatto, and Romano 1976/Ex. 1-801; Selevan, Dement, Wagoner, and Froines 1979/Ex. 1-989) are available. The Rubino, Scansetti, Piolatto, and Romano (1976/ Ex. 1-801) study found that miners and millers exposed to an average of 849 to 8470 mppcf-years (miners) or 76 to 651 mppcf-years (millers) showed no increase in the number of observed (compared to expected) deaths from causes other than silicosis. These authors concluded that the diseasecausing factor in these workers was silica rather than talc (Rubino, Scansetti, Piolatto, and Romano 1976/Ex. 1-801).

The Selevan, Dement, Wagoner, and Froines (1979/Ex. 1-989) study of 392 workers exposed to talc in five mines found nonmalignant respiratory deaths for millers to be almost eight times the expected rate, while miners experienced more than three times the expected mortality rate for NMRD. The ACGIH (1986/Ex. 1-3, p. 552) believed that the Selevan et al. (1979/Ex. 1-989) study is incomplete because confounding factors were not adequately identified and controlled for.

With regard to NIOSH's findings (Dement and Zumwald 1978), of excess cancer deaths among talc workers, OSHA is currently reviewing the scientific and toxicological data describing the effects of exposure to the nonasbestiform varieties of mineral fibers that are found in talc deposits. OSHA is considering a separate rulemaking to address this issue.

OSHA is proposing an 8-hour TWA limit of 2 mg/m3 for the respirable dust of talc containing no asbestos fibers and less than 1 percent crystalline silica in the construction, maritime, and agriculture industries. The Agency believes that this limit will protect workers in these sectors from the significant risk of nonmalignant respiratory effects associated with exposure to talc dust; OSHA considers these effects material impairments of health. In addition, promulgation of this limit will make the PEL for this substance consistent across all OSHAregulated sectors. According to the ACGIH (1986/Ex. 1-3), talc may, at

times, occur in a fibrous form. At this time, OSHA has not made any preliminary determinations with regard to the possible health consequences resulting from exposure to talc fibers.

TIN OXIDE

CAS: 7440-31-5; Chemical Formula: SnO H.S. No. 1395

OSHA has no exposure limit for tin oxide in the construction, maritime, or agriculture industry. The ACGIH has a TLV* of 2 mg/m³ as an 8-hour TWA. NIOSH has no REL for tin oxide. The Agency is proposing a PEL of 2 mg/m³ as an 8-hour TWA for tin oxide in construction, maritime, and agriculture; NIOSH concurred (Ex. 8-47, Table N1) with this limit when the Agency recently established it in general industry. Promulgation of this limit will make the PEL for tin oxide consistent across all OSHA-regulated sectors.

Tin oxide may be a white or yellowbrown powder. It is used as a reducing agent, an intermediate in the preparation of stannous salts used in the plating and glass industries, and as an ingredient in pharmaceuticals and soft abrasives (Hawley's 1987, p. 1089).

Injection of tin dust intraperitoneally into guinea pigs resulted in a nonspecific, well-vascularized chronic granulomatous reaction (Oyanguren, Haddad, and Maass 1958/Ex. 1-652). Chronic exposure to tin oxide fume and dust results in stannosis, a form of pneumoconiosis. The fume of tin oxide is considered to be a more important source of stannosis than the dust (Dundon and Hughes 1950/Ex. 1-732), but other authorities consider the quality of the dust and the duration of exposure equally important (Robertson and Whittaker 1955/Ex. 1-987). The onset of the symptoms of stannosis may be delayed for years; the appearance of the condition is signalled by difficulty in breathing. One worker who had been exposed to unspecified tin oxide levels for 22 years was tested for stannosis and registered a vital breathing capacity 70 percent of normal and a maximal breathing capacity 61 percent of the predicted value (Spencer and Wycoff 1954/Ex. 1-611). More than 150 cases of stannosis have been reported in the world literature (Robertson and Whittaker 1955/Ex. 1-987), and five cases were reported in the United States before 1954. No cases of massive fibrosis caused by exposure to tin oxide dust or fume have been reported (ACGIH 1986/Ex. 1-3, p. 574).

OSHA is proposing an 8-hour TWA PEL of 2 mg/m³ for tin oxide dust and fume in the construction, maritime, and agriculture industries. The Agency believes that this limit will protect

workers in these sectors, from the significant risks of reduced pulmonary capacity and other signs and symptoms of stannosis, which are considered material impairments of health that are associated with exposure to this substance. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

TRIMELLITIC ANHYDRIDE CAS: 552–30–7; Chemical Formula: C₉H₄O₅

H.S. No. 1409

OSHA has no exposure limit for trimellitic anhydride in the construction, maritime, or agriculture industry. In 1981, the ACGIH set 0.005 ppm (0.04 mg/ m3) as the 8-hour TLV*-TWA limit for this substance. NIOSH has no REL for trimellitic anhydride. The Agency is proposing a 0.005 ppm 8-hour TWA limit for this substance in the construction, maritime, and agriculture industries. NIOSH concurred (Ex. 8-47, Table N1) with this limit when the Agency recently established it in general industry. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Trimellitic anhydride is a colorless solid. It is used in agricultural chemicals, dyes and pigments, paints and coatings, pharmaceuticals, and surface active agents. Trimellitic anhydride is also employed as a curing agent for epoxy and other resins and as an ingredient in vinyl chloride plasticizers and various polymers and polyesters (ACGIH 1986,

p. 606).

Exposure to trimellitic anhydride (TMAN) causes irritation of the eyes, nose, skin, and pulmonary tract. NIOSH (1978n, as cited in ACGIH 1986/Ex. 1–3, p. 606) reported in a current intelligence bulletin that trimellitic anhydride should be considered an extremely toxic workplace hazard, because exposure to it can cause noncardiac pulmonary edema and immunological sensitization, as well as upper respiratory tract irritation.

Pulmonary edema has occurred in workers exposed to TMAN at unreported air concentrations: the development of pulmonary edema in these workers without upper respiratory tract irritation suggests that TMAN is a sensitizer (Rice, Jenkins, Gray, and Greenburg 1977/Ex. 1-358). Zeiss, Patterson, Pruzansky, and colleagues (1977/Ex. 1-501) described TMANrelated illnesses among a group of workers synthesizing this substance. These authors believe that there are three separate syndromes associated with TMAN exposure: rhinitis/asthma; a flu-like condition; and irritation of the

upper respiratory tract. Another case of TMAN-related occupational sensitization occurred in a worker exposed during the application of an epoxy resin coating (Fawcett, Taylor, and Pepys 1977/Ex. 1–636).

At TMAN concentrations averaging 1.5 and 2.8 mg/m³ in two processes, NIOSH reported that employees reported eye and nose irritation, shortness of breath, coughing, nausea, headache, skin irritation, and throat irritation (NIOSH 1974c/Ex. 1–1181). Pulmonary hemorrhage and hemolytic anemia have been reported in workers exposed to TMAN at unspecified levels (Ahmad, Morgan, Patterson et al. 1979/Ex. 1–460).

Rats have shown intraalveolar hemorrhage after TMAN exposures to concentrations of 0.01 ppm (Amoco Chemical Corporation 1978, as cited in ACGIH 1986/Ex. 1–3, p. 606).

Based on this study, OSHA is proposing to set the PEL in construction. maritime, and agriculture at an 8-hour TWA level of 0.005 ppm. The Agency believes that this limit will protect workers from the severe pulmonary effects, sensitization, and skin and upper respiratory tract irritation observed in workers exposed to this extremely toxic substance. The Agency believes that these effects clearly constitute material impairments of health and functional capacity within the meaning of the Act. OSHA preliminarily concludes that this limit is necessary to substantially reduce these significant risks, which were formerly uncontrolled among workers in these sectors. In addition, promulgation of this limit will make the PEL for trimellitic anhydride consistent across all OSHAregulated sectors.

WOOD DUST

CAS: None; Chemical Formula: None H.S. No. 1430A (Hard Wood) H.S. No. 1430B (Soft Wood) H.S. No. 1430C (Western Red Cedar)

Before 1980, OSHA regulated wood dust under its nuisance dust standard of 15 mg/m3 (29 CFR 1910.1000, Table Z-3). However, in a 1985 enforcement proceeding before the Occupational Safety and Health Review Commission, wood dust was held not to be covered by the nuisance dust standard, and the Agency did not regulate this substance after this decision (12 OSHC 1785). Consequently, OSHA has no current PELs for wood dust in the construction. maritime, and agriculture industries, although the prior air contaminants standard did establish PELs for wood dust in general industry. The ACGIH has a TLV*-TWA of 1 mg/m3 for hard

wood dust, and a TLV*-TWA of 5 mg/ m3 and STEL of 10 mg/m3 for soft wood dust. The ACGIH has no limit for Western Red Cedar. NIOSH has no RELs for soft- and hardwood dusts or Western Red Cedar dust in construction, maritime, and agriculture. OSHA is proposing a single 8-hour TWA of 5 mg/ m3 and a STEL of 10 mg/m3 for all hard wood and soft wood dusts except Western red cedar. For Western red cedar, a highly allergenic species of soft wood, the Agency is proposing an 8-hour TWA limit of 2.5 mg/m3. These are the limits recently established for these substances in general industry Promulgation of these limits will make the PELs for these substances consistent across all OSHA-regulated sectors.

Wood dust is defined as any wood particles arising from the processing or handling of woods. Hard woods derive from the deciduous broad-leaved flowering species of trees, and soft woods include the coniferous species that do not shed their leaves in the winter. Wood dust is produced during sawmill operations and in wood sawing and sanding procedures in furniture manufacture. Wood dust may be used as an industrial wood flour product, as an absorbent for nitroglycerin in the manufacture of dynamite, and as a filler in plastics, linoleum, paperboard, fur cleaning, and polishing agents (Sittig 1985, p. 930; Hawley's 1987, p. 1238).

Exposure to wood dust has long been associated with a variety of adverse health effects, including dermatitis, allergic respiratory effects, mucosal and nonallergic respiratory effects, and cancer. The toxicity data in animals are limited, particularly with regard to exposure to wood dust alone; there are, however, a large number of studies in humans. The discussion below first describes some of the relevant toxicological studies and then presents the record evidence on wood dust.

Animal Studies

Groups of male guinea pigs were injected intratracheally with suspensions containing 75 mg of sheesham or mango wood dust or of hemp or bagasse fibers, or 20 mg of jute fiber (Bhattacharjee, Dogra, Lal, and Zaidi 1979/Ex. 1-463; Bhattacharjee and Zaidi 1982/Ex. 1-464). Animals were sacrificed serially at intervals up to 90 days after injection. Lung examination revealed that, at 90 days, Grade I fibrosis of the lungs had occurred in the guinea pigs injected with mango or jute, while those treated with sheesham or hemp had developed Grade II pulmonary fibrosis.

In another experiment involving guinea pigs, animals were exposed by inhalation to average respirable dust concentrations of 1143 mg/m3 for 30 minutes/day. 5 days/week for 24 weeks (McMichael, DiPalma, Blumenstein et al. 1983, Ex. 1-644). Histopathological examination showed lung changes, described by the authors as moderate to severe, in all exposed guinea pigs. The changes seen included an increase in septal connective tissue components and aggregation of lymphocytes; however, no pulmonary fibrosis or extensive destruction of the parenchymal tissue occurred. The authors of this study concluded that exposure to fir bark dust may cause inflammatory changes in the lung.

Two studies examined the effect of exposing Syrian golden hamsters to beech wood dust by inhalation, with or without concurrent administration of the known carcinogen diethylnitrosamine (DEN) (Wilhelmsson, Hellquist, Olofsson, and Klintenberg 1985/Ex. 1-402; Wilhelmsson, Jernudd, Ripe, and Holmberg 1985/Ex. 1-1042; Drettner, Wilhelmsson and Lundh 1985/Ex. 1-312). In each study, the animals were divided into four separate groups. In Study I, there were 12 animals per group. Two groups were exposed to fresh beech wood dust (a hard wood dust) at a mean total dust concentration of 15 mg/m3 for six hours/day, five days/week for 36 weeks, and one of these groups was also given 1.5 mg of DEN once a week for the first 12 weeks. The third group in Study I was given the DEN doses only (positive control), and the fourth group was given no exposure at all (negative control).

In Study II, there were 24 animals in each of four groups. Two groups of animals were exposed to fresh beech wood dust at a mean total dust concentration of 30 mg/m³ for six hours/day, five days/week for 40 weeks. The positive and negative control groups were treated as in Study I.

In Study I, none of the hamsters had lung or nasal tumors or metaplasia. Four hamsters exposed to wood dust and DEN exhibited squamous cell papillomas of the trachea, as did three animals in the positive control group and one in the negative control group. No differences in organs other than the respiratory organs were seen between the treated and control groups in Study I

In Study II, all DEN-exposed hamsters had nasal lesions ranging from hyperplasias and dysplasias to papillomas. In addition, half of all DEN-exposed hamsters developed nasal adenocarcinomas, whether or not they had also been exposed to wood dust. Half of the DEN-exposed animals also had papillomas of the larynx and

trachea. In the wood-dust-exposure-only group, two of the animals had nasal lesions, one of which was an unclassifiable malignant nasal tumor and the other of which consisted of focal metaplasia with mild dysplasia. The authors concluded that exposure to wood dust did not increase the tumor incidence in DEN-exposed animals but did affect the respiratory tract of all exposed animals.

Human Studies

Dermatitis

There are a large number of case reports, epidemiological studies, and other data on the health effects of wood dust exposure in humans. Dermatitis caused by exposure to wood dusts is common, and can be caused either by chemical irritation, sensitization (allergic reaction), or both of these together. As many as 300 species of trees have been implicated in woodcaused dermatitis.

The chemicals associated with allergic reactions are generally found in the inner parts of a tree, e.g., the heartwood, and the workers most prone to these reactions are those involved in secondary wood processing (e.g., carpenters, joiners, and finishers).

The symptoms of sensitization are redness, scaling, and itching, which may progress to vesicular dermatitis and, after repeated exposures, to chronic dermatitis. The parts of the body most often affected are the hands, forearms, eyelids, face, neck, and genitals. This form of dermatitis generally appears after a few days or weeks of contact.

Allergic Respiratory Effects

Allergic respiratory responses are mediated by the immune system, as is also the case with allergic dermatitis. Many authors have reported cases of allergic reactions in workers exposed to wood dust (Sosman, Schlueter, Fink, and Barboriak 1969/Ex. 1-444; Greenberg 1972/Ex. 1-482; Pickering, Batten, and Pepys 1972/Ex. 1-655; Eaton 1973/Ex. 1-478; Booth, LeFoldt, and Moffitt 1976/Ex. 1-466; Chan-Yeung, Ashley, Corey et al. 1978/Ex. 1-622; Edwards, Brooks, Henderson, and Apol 1978/Ex. 1-950; Innocenti and Angotzi 1980/Ex. 1-1036; Bush and Clayton 1983/Ex. 1-469; Cartier, Chan, Malo et al. 1986/Ex. 1-472). Asthma is the most common response to wood dust exposure, and the allergic nature of such reactions has been demonstrated by the presence of IgE antibodies and positive skin reactions on patch testing. The beststudied of the allergic reactions to wood dust is Western red cedar (WRC)

asthma; it is estimated that 5 percent of the workers handling this species are allergic to it. However, only one study is available that relates exposure level to ventilatory function. In that study, exposure to concentrations of 2 mg/m³ of WRC dust caused significant decreases in forced vital capacity and forced expiratory volume (Vedal, Chan-Yeung, Enarson et al. 1986/Ex. 1–397). These authors also found that exposures to concentrations above 3 mg/m³ produced eye irritation.

Mucosal and Nonallergic Respiratory Effects

This section discusses changes in the structure and function of the nasal mucosa and respiratory tract that are caused by exposure to wood dust. These changes include nasal dryness, irritation, bleeding, and obstruction; coughing, wheezing, and sneezing; sinusitis; and prolonged colds. These symptoms have been observed even at wood dust concentrations below 4 mg/m³.

Bellion, Mattei, and Treves (1964, as cited in NIOSH 1987a/Ex. 1-1005) found that 97 of 225 workers (carpenters, sawmill workers, woodworkers) exposed from 3 to 24 years to the dust of several different hard woods showed radiologic evidence of pulmonary abnormalities. Black, Evans, Hadfield et al. (1974/Ex. 1-299) studied nine woodworkers from a woodworking factory in England. In all of these workers, mucociliary movement was markedly depressed, leading these authors to conclude that exposure to wood dust in the furniture industry for 10 years or more can impair mucociliary clearance. These findings were confirmed in a Danish study involving furniture makers (Solgaard and Andersen 1975/Ex. 1-443; Andersen, Solgaard, and Andersen 1976/Ex. 1-297; Andersen, Andersen, and Solgaard 1977/Ex. 1-296); compared with controls, the mucociliary transport rate was also significantly impaired in these woodworkers, and dose-response effects were noted.

A respiratory survey conducted by Chan-Yeung, Giclas, and Henson (1980/Ex. 1–474) in pulp and paper mill workers in British Columbia showed that workers exposed to wood dust at a mean total dust concentration of 0.5 mg/m³ had a slight but statistically significant decrease in pulmonary function values compared with controls. The authors concluded that the chemical preservatives used to treat the wood could also have been responsible for these adverse effects.

In a cross-sectional survey of 1,157 American woodworkers (both hard and

soft wood), Whitehead, Ashikaga, and Vacek (1981/Ex. 1-454) found that exposure to higher (10+ mg-years/m3). as compared with lower (0 to 2 mgyears/m3), dust concentrations was associated with a statistically significant and higher incidence of decreased pulmonary function. However, dose-response effects were observed only for soft wood (i.e., pine) dusts. A later study by Beckman, Ashikaga, and Whitehead (1980, as cited in NIOSH 1987a/Ex. 1-1005) examined subgroups of the workers studied by Whitehead and found no correlation between years of exposure to pine wood dust and pulmonary function.

In a pilot study of 55 workers in a North Carolina hardwood furniture plant, Goldsmith (1983, as cited in NIOSH 1987a/Ex. 1–1005) found that, at mean area wood dust concentrations of 2 mg/m³ or below, peak ventilatory flow correlated significantly with cumulative person-years of exposure. Goldsmith interpreted this finding to mean that inhalation of wood dust may impair large-airway function.

A study of Italian woodworkers showed that the number of wood-dust-exposed workers who had developed anosmia (loss of smell) was significantly higher than in a control group of nonexposed workers (Innocenti, Valiani, Vessio et al. 1985/Ex. 1–1037). Amoore (1986/Ex. 1–1029) confirmed this finding in other workers exposed to hardwood dusts.

Summary of mucosal and nonallergic respiratory effects. A large number of studies have demonstrated that occupational exposure to wood dust causes both statistically significant and nonsignificant increases in respiratory symptoms at exposure levels as low as 2 mg/m³. These symptoms range from irritation to bleeding, wheezing, sinusitis, and prolonged colds. In addition, chronic wood dust exposure causes mucociliary stasis (i.e., the absence of effective clearance) in the nose and, in some workers, also causes changes in the nasal mucosa. Several studies have demonstrated decreased pulmonary function among wood-dustexposed workers, although other studies have not confirmed these findings.

Carcinogenicity

The association between occupational exposure to wood dust and various forms of cancer has been explored in many studies and in many countries. In 1987, the International Agency for Research on Cancer (IARC) classified furniture manufacturing in Category I (confirmed human carcinogen) and carpentry in Category 2B (suspected human carcinogen). NIOSH (Ex. 8–47)

considers both hard and soft wood dust to be potentially carcinogenic in humans; for soft wood dust, NIOSH recommends a separate 6(b) rulemaking (Ex. 8–47, Table N6B). NIOSH concurred, however, with the proposed PEL of 1 mg/m³ TWA for hard wood dust (Ex. 8–47, Table N6A).

The discussion below focuses on selected U.S. studies.

Nasal and sinus cavity cancer. The earliest U.S. study of wood dust exposure and nasal cancer was conducted by Brinton, Stone, Blot, and Fraumeni (Ex. 1-468) in 1976. These authors analyzed cancer death rates between 1950 and 1969 in 132 U.S. counties having at least 1 percent of their population employed in furniture and wood-fixture manufacturing. This study revealed that the age-adjusted mortality rate for cancer of the nasal cavity and sinuses among white males in the "furniture" counties was significantly higher than in nonfurniture counties.

In a later case-control study, these authors (Brinton, Blot, Becker et al. 1984/Ex. 1–467) analyzed cases of nasal and sinus cancers occurring in North Carolina and Virginia between 1970 and 1980. This study identified a significantly elevated risk of adenocarcinomas in males working in the furniture manufacturing industry, but no increased risk among lumber, carpentry, or construction workers. There was no significant increase in the risk of squamous cell carcinoma in workers from any other wood-related industry.

In a study sponsored by the InterIndustry Wood Dust Task Force, Viren,
Vogt, and Dixon (1982, as cited in
NIOSH 1987a/Ex. 1–1005) described a
death certificate case-control study of
nasal cancer deaths for 1963 to 1977 in
North Carolina, Mississippi,
Washington, and Oregon. Findings of
this study included a relative nasal
cancer risk of 1.95 for industries
involving lumber and wood products;
however, no significant relative risk of
nasal cancer was seen for workers in
the furniture-manufacturing industry.

Imbus and Dyson conducted a study of nasal cancer and North Carolina furniture workers (1985, as cited in NIOSH 1987a/Ex. 1–1005). This study found: (1) That there was a statistically significant increase of nasal cancer among furniture workers; (2) that the nasal cancer rates among North Carolina furniture workers were much lower than those reported for English furniture workers; (3) that the number of nasal cancer deaths among North Carolina furniture workers decreased

between 1956 and 1977; and (4) that a slight excess in nasal cancer may have existed among North Carolina furniture workers but is currently either declining or nonexistent.

At present, the National Cancer Institute is conducting a cohort mortality study of 36,622 workers employed in the wood, metal, and plastic furniture manufacturing industries (Miller et al. 1988, as cited in NIOSH 1987a/Ex. 1-1005). Results are too preliminary to be

described at this time.

Summary of evidence for nasal and sinus cavity cancers. NIOSH (1987a/Ex. 1-1005) concluded that the literature clearly demonstrates an association between occupational wood dust exposure and nasal cancer. English studies first identified this link by showing a 10- to 20-times-greater incidence of nasal adenocarcinoma among woodworkers in the furniture industry than among other woodworkers and 100 times greater than in the general population. In the United States, three studies have reported a fourfold risk of nasal cancer or adenocarcinoma in furniture workers, and another study noted a similar relationship between nasal cancer and wood dust exposure. One other study failed to find such an association for furniture workers, but did find an increase among logging and timber industry workers.

Pulmonary cancer. A number of studies investigating the association between wood dust exposure and the development of lung cancer have been conducted. Milham (1974/Ex. 1-943) found a significant excess of malignant tumors of the bronchus and lung in workers who had belonged to the AFL-CIO United Brotherhood of Carpenters and Joiners of America. Only construction workers showed a statistically significant increase in lung

cancer rate.

In a study of lung cancer in Florida residents, Blot, Davies, Brown et al. (1982/Ex. 1-465) found that an elevated risk of lung cancer that was statistically significant existed among workers in the lumber and wood industry and in construction; however, smoking may have been a confounding factor in these results.

Summary of evidence for pulmonary cancer. The association between lung cancer and occupational wood dust exposure is inconclusive, although several epidemiological studies have reported increases in lung cancer among wood-dust-exposed workers.

Hodgkin's disease. The data on the relationship between exposure to wood dust and the development of Hodgkin's disease are conflicting. Milham (1967/ Ex. 1-750) and Milham and Hesser

(1967/Ex. 1-645) concluded, on the basis of a case-cohort study of 1,549 white males dying of this disease between 1940-1953 and 1957-1964, that there was an association between Hodgkin's disease and exposure to wood dust.

Another study (Spiers 1969/Ex. 1-445) concluded that men working in the wood industries in the eastern United States were at special risk for Hodgkin's disease, and suggested that pine pollen exposure might be responsible for the increase.

A Washington State epidemiological study (Petersen and Milham 1974/Ex. 1-654) also found that woodworkers had an increased risk of Hodgkin's disease, and the work of these authors was supported by the results of another study (Grufferman, Duong, and Cole 1976/Ex. 1-484), which showed a nonsignificant increase in the relative risk for Hodgkin's disease among woodworkers.

Summary of evidence for Hodgkin's disease. Although the data are conflicting, several epidemiological studies of U.S. workers do report increases in the incidence of Hodgkin's disease among woodworkers. This excess is particularly apparent among

carpenters.

Other cancers. NIOSH (1987a/Ex. 1-1005) concluded that the data on the relationship between occupational exposure to wood dust and the development of cancers other than nasal, Hodgkin's disease, or lung cancers are insufficient and inconclusive.

After a review of the record in the prior rulemaking, OSHA has determined that the health evidence for the toxicity of wood dust cannot be separately distinguished for soft wood and hard wood. In addition, the Agency was convinced in that rulemaking that most operations involve both kinds of wood and are performed on the same machines and equipment and in the same facility. Thus, any controls installed to reduce exposures would of necessity need to be sufficient to reduce airborne dust levels to the lower of the two limits (i.e., to the proposed wood dust limit of 1 mg/m3).

Some commenters involved in the earlier rulemaking found fault with several of these studies on the grounds that they involved British or other non-U.S. woodworkers (see, for example, Exs. 8-34, 191, 3-626, and 3-917), involved only a small number of subjects (see, for example, Exs. 8-34, 168, and 191), had inconsistent results (see, for example, Ex. 8-34), or failed to demonstrate a dose-response relationship between wood dust exposure and the health effect of

concern (see, for example, Exs. 8-34, 3-626, 3-917, and 191). The Inter-Industry Wood Dust Coordinating Committee (IWDCC) stated:

[T]he observations in the European studies are not representative of conditions in U.S. workplaces, especially under modern conditions * * *

The English and other European experience does not provide an accurate predictive model for the incidence of nasal cancer. * The excesses of nasal cancer observed in the European studies simply have not been observed in the United States at any time * (Ex. 3-748, pp. 2, 52).

OSHA agrees with the IWDCC that the incidence of nasal cancer seen in the United States is substantially lower than that seen in other countries, particularly in Great Britain. However, the Agency does not agree that excesses in nasal cancers, and particularly of nasal adenocarcinomas, have not been observed in American woodworkers. Several U.S. studies have reported excesses in nasal cancer risks among employees in the wood industries (Brinton, Stone, Blot, and Fraumeni 1976/Ex. 1-468; Brinton, Blot, Becker et al. 1984/Ex. 1-467; Viren, Vogt, and Dixon 1982, and Imbus and Dyson 1985, both as cited in NIOSH 1987a/Ex. 1-

In response to those commenters who argued that none of the studies described by OSHA presented sufficient dose-response data to be used as a basis for establishing a limit, the Agency emphasized that it was not relying on any single study to determine that wood dust presents a significant risk of material health impairment. Instead, OSHA made this determination on the basis of the findings in the dozens of studies reporting on the respiratory. irritant, allergic, and carcinogenic properties of wood dust. The Agency preliminarily finds the results of these studies biologically plausible and their findings reproducible and consistent. It is true that some of these studies, like all human studies, have limitations of sample size, involve confounding exposures, have exposure measurement problems, and often do not produce the kind of dose-response data that can be obtained when experimental animals are subjected to controlled laboratory conditions. What the large group of studies being relied upon by OSHA to establish the significance of the risk associated with exposure to wood dust do show is that the overall weight of evidence that such exposures are harmful and cause loss of functional capacity and material impairment of health is convincing beyond a reasonable doubt.

The Agency preliminarily finds that the health evidence clearly indicates that occupational exposure to wood dust poses a significant risk of material health impairment at the 10-mg/m³ (or particulate PEL) level. OSHA therefore believes that establishing an 8-hour PEL of 5 mg/m³ and a 15-minute STEL of 10 mg/m³ in construction, maritime, and agriculture for all wood dusts (except Western red cedar) will substantially reduce this significant risk. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

For construction, maritime, and agriculture, OSHA proposes an 8-hour TWA PEL of 2.5 mg/m³ for Western red cedar wood dust, based on its widely recognized ability to cause immunesystem-mediated allergic sensitization. A study by Brooks, Edwards, Apol, and Edwards (1980) that was submitted by the United Petitioners (Ex. 82D) reports that

a high prevalence of occupational asthma was observed among workers exposed to WRC wood dust (Ex. 82D, p. 315).

At the hearing, Dr. Brooks described occupational asthma as follows:

[T]here are spasms of the bronchial tubes, there is reduced air flow on expiration * [the extent of which depends] on the extent of the exposure, and also * * * on the duration of the exposure * * * as a consequence of this sensitization and airway injury from the sensitization and the asthmatic reaction and the various biochemical and cellular changes that occur, there develops an associated process * the airways develop an increased sensitivity and an increased broncho-spastic responsiveness to many different non-specific stimuli. So such things as cold air, dust, fumes, gases that are non-specific and wouldn't normally * * [affect] most individuals [will affect] the individual with occupational asthma. And it's [such] hyperreactive airways that cause individuals to continue to have disability and to continue to have symptoms once they leave the work place . . They develop this nonspecific bronchial hyper-reactivity which may last the rest of their life (Tr. pp. 12-339 to 12-343).

The 1980 study by Brooks, Edwards, Apol, and Edwards found a dose-related relationship between total WRC dust level and prevalence of asthma in employees in jobs with the greatest dust exposures. The Brooks et al. study found asthma in zero percent of WRC workers exposed at 0.5 mg/m³; however, at 3.56 mg/m³, this percentage rose to 5 percent.

In the prior rulemaking, the United Petitioners submitted a 1988 paper by Goldsmith and Shy that found that there is a clearly defined asthma syndrome produced by WRC (Ex. 3-362). OSHA preliminarily finds these studies

convincing evidence of WRC's allergenic potential; in addition, the Agency believes that a threshold for occupational asthma exists and lies between 2 and 3.4 mg/m³. Based on this evidence, OSHA preliminarily concludes that an 8-hour PEL of 2.5 mg/m³ is necessary to protect workers from the significant and often permenent effects of immune-mediated occupational asthma associated with exposure to WRC dust at levels above this limit.

In construction, maritime, and agriculture, OSHA is proposing a PEL of 5 mg/m3 as an 8-hour TWA and 10 mg/ m3 as a 15-minute STEL for hard and soft wood dust, with the exception of Western red cedar, for which a PEL of 2.5 mg/m3 (8-hour TWA) is being proposed. OSHA preliminarily concludes that promulgation of these exposure limits will substantially reduce the significant risk of material impairment in the form of pulmonary dysfunction (including changes in peak flow, interference with mucociliary clearance, respiratory symptoms, and chronic effects) that is associated with exposure to wood dust at the higher levels that would be permitted in the absence of any limit. In addition, promulgation of these limits will make the PELs for these substances consistent across all OSHA-regulated sectors. YTTRIUM AND COMPOUNDS CAS No: 7440-65-6 (Yttrium); Chemical

CAS No: 7440-65-6 (Yttrium); Chemical Formula: Varies with Compound H.S. No. 2169

In general industry, construction, and maritime, OSHA's current PEL for yttrium and compounds (measured as yttrium) is 1 mg/m3 as an 8-hour TWA; NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. The ACGIH TLV*-TWA for yttrium and its compounds is 1 mg/m3 as an 8-hour TWA. OSHA is retaining its current limit of 1 mg/m3 as a 8-hour TWA in construction and maritime and is proposing to extend this limit to agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Yttrium is a metallic element that is odorless, lustrous, and dark gray (ACGIH 1986, p. 641(86)). Examples of yttrium compounds of commercial interest are yttrium oxide, yttrium acetate, yttrium bromide, yttrium chloride, yttrium phosphide, yttrium sulfate, yttrium vanadate, and yttrium nitrate hexahydrate. Yttrium is used to make alloys, in the manufacture of lasers, and in nuclear technology (ACGIH 1986, p. 641(86); Hawley's 1987, p. 1246). Yttrium compounds are used as

reagents in analytical chemistry, as ingredients in electronic components, in phosphors for color television tubes, as mantles in gas and acetylene lights, end in many other applications (ACGIH 1986, p. 641(86); Hawley's 1987, p. 1246).

Yttrium and its compounds cause liver and lung damage in experimental animals. In general, yttrium's oral toxicity is low, although this substance is highly toxic when administered parenterally (Clayton and Clayton 1981, p. 1678). Acute toxicity varies with the compound and species. The intraperitoneal LD₅₀s in rats for yttrium chloride, yttrium nitrate, and yttrium oxide, respectively, are 45 mg/kg, 362 mg/kg, and 230 mg/kg (RTECS 1989, "Yttrium chloride"; RTECS 1980, "Yttrium oxide"; Sax and Lewis 1989, p. 3508). Rats injected intraperitoneally with 60 mg/kg of elemental yttrium every other day for 5 months survived, and autopsy failed to reveal accumulation of yttrium in the bones of these animals (MacDonald, Nusbaum, and Alexander et al. 1952, in ACGIH 1986). Rats exposed to yttrium oxide in the form of a single 50-mg intratracheal dose developed emphysema and diffuse granulomatous nodules within 8 months of the exposure (Clayton and Clayton 1981, p. 1682). Rats exposed to an unspecified concentration of vttrium chloride developed liver edema (with portal congestion), pleural effusions, and pulmonary hyperemia (Stokinger 1963, in Clayton and Clayton 1981, p. 1682).

There are no reports of yttrium-related exposure effects in humans; however, based on effects seen in animals, exposure to yttrium or its compounds is likely to cause lung and liver damage in overexposed individuals.

Based on this evidence, OSHA preliminarily concludes that workers in agriculture are at risk of experiencing lung and liver effects at the exposures permitted by the absence of an OSHA PEL. Accordingly, OSHA is proposing an 8-hour TWA PEL of 1 mg/m³ for yttrium and its compounds in agriculture. In addition, promulgation of this limit will make the PEL for yttrium consistent across all OSHA-regulated sectors.

Preliminary Conclusions For All Respiratory Toxicants

As Table C6-2 and the discussions above show, limits for the respiratory toxins have been established to control employee exposures to or below the airborne concentrations of these substances that have been associated with the development of acute or chronic respiratory effects. For most of these substances, the evidence is sufficient to identify the NOE or low-

effect levels that are related to these effects in humans or animals. Accordingly, OSHA preliminarily concludes that maintaining employee exposures at or below these limits will greatly decrease the likelihood that employees will be at significant risk of respiratory effects when they are exposed to these substances in the workplace. Because the chronic pulmonary disease caused by exposure to toxic dusts is often incapacitating, such exposures can effectively end the working life of severely affected individuals. Less-serious pulmonary disease can result in lost workdays, both as a result of the associated symptoms themselves and as a consequence of increased susceptibility to respiratory infections. The effects of exposure to acute pulmonary toxins, such as ozone or trimellitic anhydride, range from reduced lung function to life-

threatening pulmonary edema. OSHA has preliminarily determined that these adverse pulmonary effects constitute material impairments of health. The Agency believes that the proposed limits will substantially reduce these significant occupational risks. In addition, promulgation of these limits will make OSHA's PELs for these substances consistent across all regulated sectors.

7. Substances for Which Proposed Limits Are Based on Avoidance of Cardiovascular Effects

Introduction. OSHA is proposing to revise or establish limits for eleven chemicals on the basis of their adverse effects on the cardiovascular system. Table C7-1 lists these cardiovascular toxins, along with their CAS numbers, HS numbers, 1987-1988 ACGIH TLV®s, and NIOSH RELs (if any). In addition,

Table C7-1 shows OSHA's current PELs for these substances in construction and maritime. OSHA has no PELs for these substances in agricultural workplaces. The right-hand column in Table C7-1 shows the PELs that were recently established for these cardiovascular toxins in general industry; these are the limits being proposed today for construction, maritime, and agricultural workplaces. Promulgation of these limits will thus make OSHA's PELs for these 11 substances consistent across all regulated sectors.

Description of the Health Effects. Although the cardiovascular system can be adversely affected in many different ways by exposure to toxic substances, the adverse effects caused by exposure to the eleven chemicals shown in Table C7-1 are limited to three categories: (1) Cardiac sensitization; (2) vasodilation;

and (3) atherosclerosis.

Table C7-1.—Substances For Which Proposed Limits Are Based on Avoidance of Cardiovascular Effects

H.S. Number/Chemical Name	CAS No.	Current OSHA PEL in Construction, and Maritime ¹	1987-1988 ACGIH TLV ²	NIOSH REL 3	Proposed OSHA PEL in Construction Maritime, and Agriculture ¹
2008 Antimony and compounds-	7440-36-0 75-15-0				0.5 mg/m³ TWA. 4 ppm TWA, 12 ppm
1087 Chloropentafluoroethane	76-15-3		1000 ppm TWA	Ceiling (15-min).	STEL, Skin. 1000 ppm TWA.
2058 Dichlorodifluoromethane			1000 ppm TWA		
2060 Dichlorotetrafluoroethane	76-14-2		1000 ppm TWA		
1170 Ethylene glycol dinitrate:	628-96-6		0.3 mg/m³ TWA, Skin		0.1 mg/mª STEL, Skin.
1180 Fluorotrichloromethane	75-69-4	1000 ppm TWA	1000 ppm Celling		1000 ppm Ceiling.
1290 Nitroglycerin	55-63-0		0.5 mg/m³ TWA, Skin		0.1 mg/m³ STEL, Skin.
2124 Pentachlorophenol	87-86-5	0.5 mg/m³ TWA, Skin	0.5 mg/m3 TWA, Skin		0.5 mg/m3 TWA, Skin.
1364 Sodium azide	26628-22-8		0.1 ppm Ceiling		
1403 1,1,2-Trichloro-1,2,2-trifluoroethane	76–13–1	1000 ppm TWA			HN _s); 0.3 mg/m³ Ceiling, Skin (as NaN _s). 1000 ppm TWA, 1250 ppm STEL.

OSHA's PELs do not currently apply in Agriculture; OSHA's TWA limits are for 8-hour exposures, its STELs are for 15 minutes unless otherwise specified, and its ceilings are peaks not to be exceeded for any period of time.

2 The ACGIH TLV *-TWA is for an 8-hour exposure; its STELs are 15-minute limits not to be exceeded more than 4 times in any working day, with a minimum of 60 minutes between successive STEL exposures; and its ceilings are peaks not to be exceeded for any period of time.

3 NIOSH TWA limits are for 10 hour/day, 40 hour/week exposures unless otherwise specified, and its ceilings are peaks not to be exceeded for any period of time unless a duration is specified in parentheses.

time unless a duration is specified in parentheses.

* This is the limit recommended by NIOSH for ethylene glycol dinitrate or nitroglycerin alone or for a mixture of the two.

Because these effects can have potentially disabling or life-threatening outcomes, OSHA has preliminarily concluded that these effects clearly constitute material impairments of health and functional capacity.

Cardiac sensitization is a form of sensitization that is not mediated by the immune system; instead, chemicals that are cardiac sensitizers make the heart sensitive to the effects of a class of biological compounds called sympathomimetic amines. The physiological action of sympathomimetic amines is to stimulate the heart to beat faster; the hormone

adrenaline (also called epinephrine) is an example of a sympathomimetic amine. Adrenaline is normally secreted into the bloodstream when the body anticipates an increase in physical exertion, such as occurs when someone is frightened. To increase the heartbeat rate, individuals must be exposed to a concentration (dose) of epinephrine that is equal to or higher than the no-effect level for this substance. The effect of a cardiac sensitizer is to lower the noeffect level so that the heartbeat rate is stimulated by exposure to a lower concentration (or dose) of adrenaline. The region of the heart that becomes

sensitized is the pacemaking and conduction system, which determines the rhythm and rate of the heartbeat. Unregulated or unnecessary interference with this region of the heart can result in arrhythmia, an abnormality in the rhythm or rate of the heartbeat (Levy 1985/Ex. 1-210). The clinical consequences of arrhythmia vary among individuals, e.g., a young person with a healthy heart may not be adversely or seriously affected by an arrhythmia. However, fatal arrhythmias have occurred in healthy young people, and arrhythmias can result in cerebral or myocardial ischemia, shock, or

congestive heart failure in older people or in individuals whose cardiovascular systems have already been compromised.

Vasodilators are compounds that cause blood vessels to expand, resulting in a decrease in blood pressure (hypotension) and a decrease in the amount of blood reaching the organs. Acute hypotension is a common cause of shock ("Harrison's Principles of Internal Medicine," 10th ed., Petersdorf et al. 1983). Chronic hypotension may result in a number of symptoms, including lethargy, weakness, easy fatigability, and dizziness or faintness.

Atherosclerosis is a serious disease produced by a degenerative process in the arteries. Plaques containing lipids. complex carbohydrates, blood products, and calcium form on the inside walls of arteries, usually on the major blood vessels. These plaques are also called atheromas; their presence makes arteries narrower. Depending on which arteries in the body contain atheromas, different clinical consequences may result; these include renal hypertension. stroke, and myocardial ischemia (inadequate circulation of blood to the myocardium) (Balazs, Hanig, and Herman 1986/Ex. 1-176). Some chemicals can enhance or accelerate the formation of atheromas and thereby encourage the development of atherosclerosis, a major cause of coronary heart disease.

Dose-Response Relationships and Cardiac Effects

For several of the chemicals shown in Table C7–1, the proposed limits are based primarily on epidemiological studies, health surveys, and case reports indicating that occupationally exposed workers subjected to concentrations above a no-adverse-effect level experience these cardiovascular effects. However, human data for several other of these chemicals are scarce. For these chemicals, the proposed limits are based on the results of studies in laboratory animals.

Chemically induced cardiovascular disease occurs in a pattern that corresponds to a typical effect-level dose-response relationship; that is, an exposure level and exposure duration exist below which the substance appears unlikely to exert an adverse effect. Thus, the limits proposed for substances in this group are designed to maintain exposures below this apparent no-adverse-effect level. For the eleven substances in this group of cardiovascular toxins, the available toxicologic data and OSHA's preliminary findings are described below.

ANTIMONY AND COMPOUNDS CAS: 7440–36–0; Chemical Formula: Varies

H.S. No. 2008

OSHA's current PEL for antimony and its compounds (measured as antimony, or Sb) in general industry, construction, and maritime is 0.5 mg/m³ as an 8-hour time-weighted average. There is no PEL in agriculture. Both NIOSH and the ACGIH also have an 8-hour TWA limit of 0.5 mg/m³ for this substance and its compounds. OSHA is proposing to establish an 8-hour TWA PEL of 0.5 mg/m³ for antimony and its compounds in agriculture. This is the limit recently established for these substances in general industry.

Antimony is a shiny, silvery or gray metal or a yellow crystalline solid (New Jersey Department of Health 1986). Some of the compounds of antimony in industrial use include antimony lactate, antimony pentachloride, antimony pentafluoride, antimony potassium tartrate, antimony tribromide, antimony trichloride, antimony trifluoride, and antimony trioxide. These compounds find use in various applications: fabric dyeing; metal-coloring; catalytic reactions; insecticidal applications; the production of porcelain, pottery, and pigments; and in decolorizing glass. When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Antimony and its compounds pose hazards to exposed individuals by several routes of exposure: inhalation. ingestion, and eye or skin contact. Experimental animals exposed to antimony and its compounds by inhalation develop pulmonary irritation; autopsy of acutely poisoned animals reveals enlargement of splenic follicles and fatty degeneration of the liver (NIOSH/OSHA 1988). The oral LDso in rats for elemental antimony is 100 mg/kg (Genium 1989). For antimony trifluoride, the oral LD50 in mice is 804 mg/kg (Genium 1989); for antimony trichloride. the oral LDso in rats is 525 mg/kg (RTECS 1990). For antimony pentachloride, the LCso in rats is 720 mg/ m3 for 2 hours (RTECS 1990).

Guinea pigs exposed chronically (duration not specified) to 45 mg/m³ of antimony trioxide developed extensive pneumonitis; at autopsy, they also exhibited fatty degeneration of the liver (Dernehl, Nau and Sweets 1945). Rabbits and rats exposed for 100 hours/month for 10 or 14.5 months to 100 to 125 mg/m³ concentrations of antimony (rats) or to 89 mg/m³ concentrations of antimony (rabbits) developed lipoid pneumonia

(Gross 1955). Female rats exposed to antimony trioxide at a concentration of 3.2 or 4.2 mg/m³ for 6 hours/day, 5 days/week for 1 year developed lung tumors (EPA 1983). Rats, rabbits, and dogs exposed 7 hours/day to antimony sulfide (at an antimony concentration of 3.07 to 5.6 mg/m³) for 6 weeks developed functional disorders of the heart and parenchymatous degeneration of the myocardium (Brieger, Semisch, Stasney, and Piatner 1954).

In humans, exposure to antimony compounds causes, depending on the specific compound, irritation of the eves. mucous membranes, and skin, pneumoconiosis, chronic cough. gastrointestinal symptoms, and cardiac effects (Potkonjak and Pavlovich 1983: Taylor 1966). Workers exposed to antimony trisulfide, antimony trioxide. or antimony trichloride have developed pulmonary fibrosis, electrocardiogram changes, heart muscle changes, and sudden death from heart attack (NIOSH/OSHA 1988). In a group of abrasive industry workers examined after exposure to mean antimony levels of 3 to 5 mg/m3 for 8 months to 2 years. 37 of 75 were found to have changes in their electrocardiograms, 14 of 75 had elevated blood pressure readings, and 7 of 111 had ulcers; six sudden heartrelated deaths and two other deaths from chronic heart disease had occurred among these workers (Brieger, Semish. Stasney, and Piatner 1954). Dermal effects, known as "antimony spots" have been recognized in antimony workers for years, but the pneumoconiotic potential of these compounds has only been recognized in the last 20 years or so (McCallum 1963). Antimony spots take the form of papules and pustules around the sweat and sebaceous glands (McCallum 1963). Exposure to antimony halides or oxides causes irritation of the eyes, nose, and upper respiratory tract in exposed workers (Taylor 1968; Cordasco 1974). Increased rates of spontaneous abortions and premature births have been reported in metallurgical workers in the Soviet Union (Belyaeya 1967): there is also some evidence that exposure to antimony may cause an increased risk of lung cancer (Proctor. Hughes, and Fischman 1988, p. 79).

Based on the evidence discussed above, OSHA preliminarily concludes that, in the absence of a limit, agricultural workers who are exposed to antimony or its compounds are at increased risk of irritation of the eyes, nose, and upper respiratory tract; pneumoconiosis; skin rashes and pustules; spontaneous abortion and premature birth of offspring; and,

perhaps, of lung cancer. The Agency believes that the proposed permissible exposure limit of 0.5 mg/m3 (measured as antimony) will reduce these significant risks among agricultural workers. In addition, promulgation of this limit will make OSHA's PEL for these substances consistent across all regulated sectors.

CARBON DISULFIDE CAS: 75-15-0; Chemical Formula: CS2 H.S. No. 1070

In construction and maritime, OSHA's current limit for carbon disulfide is 20 ppm as an 8-hour TWA, with a skin notation. OSHA has no PEL for this substance in agriculture. The 1987-1988 ACGIH TLV*-TWA for this substance is 10 ppm, with a skin notation. NIOSH has recommended exposure limits of 1 ppm as a 10-hour TWA and 10 ppm as a 15minute ceiling. NIOSH also concurs (Ex. 8-47, Table N1) with the limits being proposed. OSHA is proposing an 8-hour TWA PEL of 4 ppm and with a 12-ppm 15-minute STEL for carbon disulfide, with a skin notation. These are the limits recently established for carbon disulfide in general industry.

Carbon disulfide is a clear, colorless, or faintly yellow liquid with a strong, disagreeable odor. This substance is used in the manufacture of soil disinfectants; as a veterinary anthelmintic; as a solvent and corrosion inhibitor; as a space and commodity fumigant; as a catalyst; and as a chemical intermediate in rayon and other manufacturing processes (HSDB 1985).

Carbon disulfide is a narcotic and a central nervous system toxin in animals. The oral LD50 in rats is 3188 mg/kg, and the lowest lethal inhalation dose in the same species is 25 g/m3 for 2 hours (RTECS 1989). Animals acutely poisoned by exposure to carbon disulfide show excitement followed by muscular weakness, collapse, coma, and death by respiratory failure (HSDB 1985); at autopsy, animals showed degenerative changes in the ganglion cells of the retina and optic nerve (Grant 1986). Carbon disulfide has shown embryotoxic and fetotoxic effects in rats, mice, and rabbits by the oral and inhalation routes of administration (RTECS 1990); it also has reproductive effects in animals of several species (RTECS 1990). In humans, carbon disulfide causes adverse cardiovascular effects and damages the central and peripheral nervous systems (Proctor, Hughes, and Fischman 1988, p. 120). Occupational exposure to carbon disulfide has caused mental disturbances, including confusion,

irritability, insomnia, and overt psychosis (Rom 1983, p. 318).

OSHA is proposing to reduce the exposure limits for carbon disulfide on the basis of the results of several studies of British and Finnish workers (Tiller, Schilling, and Morris 1968/Ex. 1-92; Seppalanin and Tolonen 1974/Ex. 1-100; Tolonen et al. 1975/Ex. 1-392; Tolonen, Nurminen, and Hernberg 1979/Ex. 1-158; Sweetnam, Taylor, and Elwood 1987; and Nurminen and Hernberg 1985). These studies, taken as a whole, indicate that long-term exposure to carbon disulfide concentrations at levels between 10 and 40 ppm is associated with an excess risk of adverse neurological effects and with excess mortality for coronary heart disease.

The study by Tiller et al. (1968/Ex. 1-92) of British rayon workers was the first to relate exposure to carbon disulfide with the development of coronary heart disease. These authors found that, among men employed for more than 10 years in the rayon industry and followed from 1950 to 1964, those exposed to carbon disulfide had death rates from coronary heart disease that were more than twice the rate in other rayon workers. Thus, the Tiller et al. (1968/Ex. 1-92) study demonstrated that 10 years or more of exposure to carbon disulfide was associated with a significantly elevated risk of coronary

disease.

The United Kingdom's threshold limit value for carbon disulfide, which had been 20 ppm in the 1960s, was reduced to 10 ppm in the 1970s. To examine the effect of this reduced limit on occupational risk, Sweetnam et al. (1987) conducted a follow-up study on the cohort first described by Tiller et al. (1968/Ex. 1-92). The health status and cause of death for 2,848 members of this cohort were ascertained up to the end of 1982. Exposure scores representing cumulative exposure to carbon disulfide were developed for each cohort member, based on an analysis of personal and area sampling results, job category, and time spent in each job category. Sweetnam et al. (1987) found the pattern of mortality similar to that found by Tiller, Schilling, and Morris (1968/Ex. 1-92); among spinner operators, who had the highest CS2 exposures of any job category, 73 deaths from ischemic heart disease (IHD) were identified, compared with 42.5 expected deaths (SMR=172), a finding that was statistically significant. A statistically significant trend was found between cumulative exposure since first exposure and incidence of IHD mortality, which indicates a doserelated effect. A second (and perhaps more important) finding of this study

was that recent (or current) exposure to carbon disulfide, as well as total cumulative exposure, were both risk factors for IHD. The authors established this association by examining the relationship between IHD mortality risk and each worker's total CS2 exposure in the two years preceding death or the two years before the end of the study. The third result of this study was that workers with current CS2 exposure also had significantly higher risk than workers whose exposure had ceased. The dose-related relationship between increased IHD mortality risk and recent exposure to carbon disulfide suggested to the authors of this study that the effect of carbon disulfide on the cardiovascular system was direct and reversible.

Thus, the Sweetnam et al. (1987) follow-up study determined that there is a relationship between the risk of IHD mortality and increased cumulative exposure to CS2. Among workers who terminated exposure, this risk declined to non-statistically significant levels after one year of no exposure. However, risk continued to be elevated among workers who continued to be exposed or who had not been exposure-free for a full year. OSHA believes that the findings of this study indicate that cumulative CS2 dose from time of first exposure is a risk factor for IHD, and that this elevated risk continues unless exposure is terminated. That is, OSHA believes that workers who have been exposed to CS2 in the past continue to be at increased risk as long as they are exposed to CS2, even when their recent exposure is to lower levels (approximately 10 ppm, the current limit in the United Kingdom).

This interpretation appears to have been confirmed by Nurminen and Hernberg (1985) in their follow-up study of 343 Finnish rayon workers who had been exposed to carbon disulfide for at least five years. Health status data were obtained for these workers for the period 1967 to 1982. In 1972, a preventive program had been instituted that included the establishment of a 10-ppm exposure limit and the removal of workers at high risk of coronary disease from continued exposure to carbon disulfide. Median exposure levels (calculated largely from area samples) for the period 1975 to 1980 did not exceed 5 to 6 ppm, and third-quartile exposure levels did not exceed 10 ppm. These levels were about half those reported for the period 1967 to 1975.

Nurminen and Hernberg (1985) reported a 4.7-fold increase in IHD mortality incidence for the period 1967 to 1972, i.e., for the period prior to the

establishment of the protective measures described above. Five years after these measures were instituted, only 19 percent of the cohort continued to be exposed to carbon disulfide (compared to 53 percent of the cohort exposed in 1972). The relative risk for the first seven years of follow-up (1967 to 1974) was 3.2, compared with a relative risk of 1.0 for the last eight years (1974 to 1982). The excess risk of IHD mortality thus declined steadily throughout the follow-up period; this trend was statistically significant. The authors concluded that "* * * the cardiotoxic effects of CS2 are reversible in the sense that the cessation of, or a radical decrease in, exposure reduces the risk of cardiovascular mortality to background levels" (Nurminen and Hernberg 1985, p. 34). Thus, the Nurminen and Hernberg (1985) study shows that reducing exposure levels below 10 ppm (combined, in their case. with a rigorous medical removal program to terminate exposure for employees who had developed signs or symptoms of coronary heart disease) can reduce the significant risk of IHD mortality to baseline levels.

It should be noted, however, that this study should not be interpreted to mean that 10 ppm is sufficiently protective. The average exposure of this group was to concentrations of about 5 ppm. In addition, this workforce was highly selective, because workers having a risk factor for cardiovascular disease had been removed. As many as 50 percent of all middle-aged men have some risk factors for cardiovascular disease; however, a medical screening program as rigorous as the one in place for the workers in this study would undoubtedly screen out perhaps as many as half the workforce. Furthermore, a workforce this selective would be expected to have a belowaverage rate of cardiovascular disease; instead, it should be noted that they actually had an average cardiovascular disease risk.

In the earlier PEL rulemaking, OSHA proposed a 1-ppm 8-hour TWA for carbon disulfide, and many commenters, including NIOSH (Exs. 8-47 and 193), the AFL-CIO (Ex. 194), and Dr. James Melius, Director of the Division of Occupational Health and Environmental Epidemiology of the New York Department of Health (Ex. 152), supported this proposed limit. Some participants (Exs. 3-747, 3-1158, 8-19, 8-45, 31, 125, and 174; Tr. pp. 4-74 to 4-107) in the prior rulemaking argued that the evidence in the studies described above did not support a limit of 1 ppm; these commenters argued that the cohorts in

which excess deaths from cardiovascular disease had been seen included workers who had been exposed for many years to levels of carbon disulfide much higher than the 10- to 40-ppm levels generally reported in these studies.

OSHA responded to these commenters in the preamble to the final rule for air contaminants in general industry (54 FR 2537) by stating that, in the Agency's opinion, both cumulative exposure and current exposure are risk factors for IHD among CS₂-exposed workers. Further, OSHA stated that the Agency believes that this excess risk continues for as long as exposure continues.

A recent epidemiologic study by MacMahon and Monson (1988/Ex. 125) also supports carbon disulfide's cardiotoxicity in the workplace setting. The cohort in this study consisted of 10,418 men employed between 1957 and 1979 in the four principal viscose rayon plants in the United States, and the mortality status of the cohort was ascertained up to mid-1983. Cohort members were placed into general exposure categories according to job title; these categories were highest, intermediate, variable, least, and none. The authors found no significant increase in overall mortality in the 4,448 employees with the highest potential for CS2 exposure compared with the mortality among 3,311 employees with no CS2 exposure. However, there was a statistically significant excess of arteriosclerotic heart disease (ASHD) among the most heavily exposed workers (242 deaths versus 195.6 expected). No clear relationship was observed between exposure duration or latency and excess ASHD mortality; however, the data suggest that the risk was higher among employees exposed to CS2 for 15 or more years and among employees hired prior to 1960.

In addition, MacMahon and Monson (1988/Ex. 125) found a statistically significant increase in the SMR (SMR=150) for ASHD among members of the cohort who had been exposed to CS2 in the year immediately preceding death or in the year immediately preceding the termination date of the study (Ex. 125, Attachment B, Table 7, p. 702); however, there was no general pattern of increased SMRs among cohort members whose time since last exposure exceeded one year. This finding is consistent with the results of the British studies, which also found an increased risk of heart disease among recently exposed employees but not among employees who had left their

In the prior rulemaking, one commenter (1988/Ex. 125) interpreted the MacMahon and Monson study as meaning that U.S. workers employed since 1960 were not at risk of ASHD (Tr. 4-96). However, OSHA disagrees with this view and believes that the results of the MacMahon and Monson (1988/Ex. 125) study are supportive of and consistent with those of the British and Finnish studies discussed above, for the following reasons. First, all of the studies clearly demonstrate a positive association between exposure to carbon disulfide and an increased risk of mortality from heart disease. Second. studies from all three countries link the excess risk to cumulative CS2 exposure. Third, studies from all three countries demonstrate that this significant risk can be substantially reduced or eliminated by reducing or stopping exposure, even after a considerable CS2 dose has accumulated; both the U.S. and British studies report a significantly increased risk of death from heart disease among workers who were recently exposed but no increased risk among workers whose exposures had ended one year or longer prior to death or prior to the end of the study. Moreover, the Finnish study reported steady declines in heart disease mortality among workers after exposure levels were reduced to below 10 ppm and a rigorous medical screening and removal program was instituted. These findings would appear to demonstrate that current or continued exposure to carbon disulfide at the levels presently encountered in these facilities is as important a risk factor for heart disease mortality as cumulative exposure. Therefore, reducing exposures to below 10 ppm does not by itself appear to eliminate risk.

In addition to evidence that carbon disulfide is a cardiovascular toxin, there is a substantial body of evidence that exposure to carbon disulfide presents a fetotoxic hazard and that this substance may also be a teratogen. Some of the early (pre-1977) animal data on reproductive effects were reviewed in the NIOSH criteria document (1977b/Ex. 1-260) on carbon disulfide. There are also two more recent and relevant reports (Cai and Bao 1981 and Hemminki and Niemi 1982). Cai and Bao (1981) reported increased incidences of menstrual disturbances and of pregnancy toxemia, a potentially lethal condition, among rayon workers and also presented evidence that CS2 can cross the placental barrier and be secreted into mothers' milk. The Hemminki and Niemi (1982) study found a significantly elevated incidence of

spontaneous abortions among women employed in viscose rayon facilities in Finland; however, data on the specific CS2 exposure levels were generally lacking.

The Rohm and Haas Company submitted a summary (Ex. 10-5) of the evidence on the reproductive toxicity of carbon disulfide to the docket in the prior rulemaking; this information shows that carbon disulfide has caused fetal deaths and malformations in CS2exposed laboratory animals. Rohm and Haas described studies in which oral administration of CS2 to female rats during gestation produced both teratogenic and fetotoxic effects. These effects were magnified in the F2 offspring of the prenatally exposed F1 generation, which suggests that CS2 has a multi-generational effect that continues to cause malformations in successive generations.

Jones-Price et al. (1984) found both maternal and fetal toxicity in CD rats exposed orally to 200, 400, or 600 mg/kg/ day CS2 during days 6 through 15 of gestation. No dose-related increases in the incidence of teratogenicity were observed. In another report, these authors found significant dose-related increases in percent resorptions/litter, percent non-live (dead or resorbed)/ litter, and percent of fetuses affected (non-live and malformed)/litter among New Zealand White rabbits exposed orally to 25, 75, or 150 mg/kg/day during days 6 through 19 of gestation. The percentage of malformed fetuses per litter increased with dose and was statistically significant at the highest dose tested

In an inhalation study, Hardin, Bond, Sikov et al. (1981/Ex. 1-699) exposed rats and rabbits to 20 or 40 ppm CS2 for 6.5 hours per day during days 1 through 19 (rats) or 1 through 24 (rabbits) of gestation. No embryotoxic or fetotoxic effects were noted, indicating that 40 ppm is a no-effect level for these effects in rats and rabbits. It would thus appear that the lowest-reported-effect level (25 mg/kg/day) documented by Jones-Price et al. (1984) for embryotoxicity/ fetotoxicity in rabbits corresponds to an equivalent airborne exposure of 58 ppm; this lowest-reported-effect level is in close agreement with the no-effect level reported by Hardin et al. (1981/Ex. 1-699) for the same species.

OSHA believes that this evidence, which shows that fetotoxic and teratogenic effects are associated with exposure to carbon disulfide, warrants concern, particularly in light of the fact that CS2 has been shown to cause multigenerational effects in rats. Based on the significant risks of reproductive effects and cardiovascular disease,

OSHA has preliminarily concluded that a substantial reduction in the PEL for carbon disulfide is justified for workers in the construction, maritime, and agriculture industries. The 4 ppm level proposed thus provides a 10-fold "safety factor" for fetotoxic effects in animals. Secondly, 10 ppm does not appear to be sufficiently protective to eliminate significant risk of cardiovascular disease. The additional protection of 4 ppm is needed for these effects. The Agency preliminarily finds that the proposed limits of 4 ppm as an 8-hour TWA and 12 ppm as a STEL, with a skin notation, will protect workers in these sectors from these significant risks, which constitute material health impairments that are potentially associated with exposure to this substance. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

CHLOROPENTAFLUOROETHANE CAS: 76-15-3; Chemical Formula:

ClCF2CF3 H.S. No. 1087

OSHA has no limit for chloropentafluoroethane (FC-115) in construction, maritime, or agriculture. The ACGIH TLV* for this substance is 1000 ppm as an 8-hour TWA; NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL for chloropentafluoroethane of 1000 ppm in construction, maritime, and agriculture. This is the limit recently established for this substance in general

Chloropentafluoroethane is a colorless, nonflammable gas that has a mild, ether-like odor. Chloropentafluoroethane is used primarily as a refrigerant; a dielectric gas; an aerosol propellant; and in food

preparation (HSDB 1989).

At high concentrations, this substance is an asphyxiant and a cardiac sensitizer. At lower concentrations and in liquid (pressurized) form, contact of FC-115 with the skin causes frostbite and burns (Braker and Mossman 1980, p. 176). Rats, mice, rabbits, and dogs have tolerated six-hour daily exposures to 100,000 ppm FC-115 for 90 days without adverse effects (Clayton, Hood, Nick, and Waritz 1966/Ex. 1-952), and laboratory animals have tolerated exposure to 200,000 ppm for 3.5 hours daily, five days per week, for four weeks (Weigand 1971/Ex. 1-1102). However, dogs exposed to a 10- or 20-percent concentration of FC-115 (approximately 100,000 to 200,000 ppm) showed central nervous system depression (Aviado and Belej 1975), and rats exposed to 190,000

ppm for between 4 and 26 minutes developed apnea (cessation of breathing) (HSDB 1989). FC-115's potential for cardiac sensitization caused one of 13 unanesthetized dogs to develop cardiac sensitization after exposure to 150,000 ppm intravenously (Trochimowicz, Azar, Terrill, and Mullin 1974/Ex. 1-448; Reinhardt, Azar. Maxfield, et al. 1971). Several other studies indicate that unanesthetized dogs, rats, and monkeys exposed to concentrations between 100,000 ppm and 200,000 ppm may show increased blood pressure, accelerated heart rate, myocardial depression, or altered pulmonary effects under certain conditions (Belej and Aviado 1975/Ex. 1-462; Friedman, Cammarato, and Aviado 1973/Ex. 1-416; Aviado and Belej 1975/Ex. 1-616).

Based on this evidence in humans and animals, OSHA is proposing an 8-hour TWA permissible exposure limit of 1000 ppm for chloropentafluoroethane to protect workers in construction, maritime, and agriculture from the significant risk of FC-115-related cardiac effects. This limit includes a reasonable safety factor in light of the seriousness of the effect and the need to account for interspecies variation. The Agency believes that these health effects constitute material impairments of health and functional capacity and that the PEL is necessary to reduce these risks. Promulgation of this limit will also make OSHA's PEL for this substance consistent across all regulated sectors. DICHLORODIFLUOROMETHANE CAS: 75-71-8; Chemical Formula: CCl₂F₂

H.S. No. 2058

OSHA's current PEL for dichlorodifluoromethane in general industry, construction, and maritime is 1000 ppm as an 8-hour TWA; there is no PEL in agriculture. The ACGIH TLV*-TWA for dichlorodifluoromethane is 1000 ppm; NIOSH has no REL for this substance but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour TWA of 1000 ppm for dichlorodifluoromethane in agriculture. This action will make the PEL for this substance consistent across all OSHA-regulated sectors.

Dichlorodifluoromethane, also called Fluorocarbon 12, is a colorless. nonflammable gas. It is odorless in concentrations below 20 percent by volume; at higher concentrations, it has a mild ether-like odor similar to that of carbon tetrachloride (Braker and Mossman 1980, p. 231). Dichlorodifluoromethane is used as a refrigerant, a blowing agent for polymeric foams, and a fixative for

frozen tissue sections; formerly, it was widely used as an aerosol propellant (ACGIH 1986, p. 181; HSDB 1990).

Dichlorodifluoromethane is an irritant and a narcotic in humans and animals: at very high concentrations, inhalation of this substance causes asphyxiation. Dichlorodifluoromethane also causes cardiac sensitization in animals. The LC50 in rats is 800,000 ppm for 30 minutes (RTECS 1990). Dogs, monkeys, and guinea pigs exposed to a 200,000ppm concentration of dichlorodifluoromethane for several hours daily for several days exhibited the following signs: Tremors, ataxia, salivation, and lacrimation (Grant 1986, p. 322). Rats exposed to a 10,000-ppm concentration of this substance for 6 hours/day for 90 days and dogs exposed to a 5,000-ppm concentration on the same regimen showed no adverse effects (Leuschner, Neumann and Hubscher 1983). Cardiac arrhythmias were observed in five of 12 dogs exposed both to a 50,000-ppm concentration of dichlorofluoromethane and to intravenous epinephrine (Reinhardt, Azar, Maxfield et al. 1971). Carcinogenicity and teratogenicity studies involving this substance have been negative (Maltoni, Lefemine, Tovoli, and Perino 1988; Brar, Jackson, Traitor et al. 1976).

In humans, dichlorodifluoromethane causes eye and upper respiratory tract irritation as well as central nervous system depression. Volunteers exposed to a 200,000-ppm concentration of dichlorodifluoromethane for a brief (not further specified) time reported experiencing eye irritation and central nervous system effects; all effects reversed after termination of exposure (Proctor, Hughes, and Fischman 1988, p. 187). When the concentration was reduced to 110,000 ppm and the duration was increased to 11 minutes, volunteers experienced amnesia, cardiac arrhythmias, and a decrease in their level of consciousness (Proctor, Hughes, and Fischman 1988, p. 187). At an exposure level of 40,000 ppm for 80 minutes, subjects experienced ringing in the ears, a feeling of apprehension, and generalized paresthesia; their speech was also slurred (Proctor, Hughes, and Fischman 1988, p. 187). Two volunteers exposed to 10,000 ppm for 2.5 hours showed psychomotor impairment on testing (Azar, Reinhart, Maxfield, et al. 1972). Exposing volunteers to a 1000ppm concentration of dichlorodifluoromethane for 8 hours/ day for 17 days, however, caused no exposure-related effects (Stewart, Newton, Baretta, et al. 1978). A man who accidentally punctured a

refrigerator coil containing dichlorodifluoromethane subsequently developed bronchopneumonia and died; he is believed to have aspirated the freezing liquid or vapor (Laurain 1964). A man chronically exposed to dichlorodifluoromethane at work (concentrations unknown) developed chronic pharyngolaryngeal edema, with the following signs and symptoms: dysphagia, dysphonia, and inspiratory dyspnea; these effects disappeared after the man moved to another job (Tanturri, Pia, and Benzi 1988).

Based on this evidence in humans and animals, OSHA preliminarily concludes that workers in agriculture are at significant risk of experiencing these exposure-related effects and that implementation of the proposed 8-hour TWA PEL of 1000 ppm will substantially reduce these risks. Adoption of the proposed limit will also ensure consistency in OSHA's limit for this substance in all regulated sectors.

DICHLOROTETRAFLUOROETHANE CAS: 76–14–2; Chemical Formula:

CClF₂CClF₂ H.S. No. 2060

The current OSHA limit for dichlorotetrafluoroethane in general industry, construction, and maritime is an 8-hour TWA PEL of 1000 ppm. OSHA does not currently have a limit for this substance in agriculture. The ACGIH has a TLV*-TWA of 1000 ppm for dichlorotetrafluoroethane; NIOSH has no REL but concurs (Ex. 8-47, Table N3A). OSHA is proposing an 8-hour TWA PEL of 1000 ppm for this substance in agriculture; this action will ensure consistency in the limit for dichlorotetrafluoroethane in all OSHA-regulated sectors.

Dichlorotetrafluoroethane is a colorless, nonflammable gas with a faint ether-like odor at high concentrations (Merck 1983, pp. 373–374). It is shipped as a liquefied gas. This substance is used as a solvent; in fire extinguishers; as a refrigerant, blowing agent, and dielectric fluid; and in air conditioning systems (Hawley's 1987, p. 382; Hazardous Substance Fact Sheet 1986, p. 1).

At extremely high concentrations, dichlorotetrafluoroethane can cause asphyxia. It also causes cardiac sensitization, central nervous system depression, and respiratory and eye irritation in humans and experimental animals (Proctor Hughes and Fischman 1988, p. 193; Gosselin 1984, P. II–160). The LC₅₀ values for rats, mice, and rabbits are 720,000, 700,000, and 750,000 ppm, respectively, for 30-minute exposures (RTECS 1987). Local inflammation of the skin and eyes was

caused by repeated spraying of the skin or eyes of rats or rabbits with dichlorotetrafluoroethane (Quevauviller 1965; Quevauviller et al. 1964, in ACGIH 1986, p. 191). Exposures to concentrations of 300,000 to 400,000 ppm disturbed the equilibrium of rats and guinea pigs exposed to these concentrations for 2 hours (Scholz 1962, in ACGIH 1986, p. 191). Guinea pigs exposed for 2 hours to concentrations ranging from 8000 to 47,000 ppm developed irregular breathing patterns but showed no other signs of toxicity (Nuckolls 1933, in ACGIH 1986, p. 191). Although dogs survived single 8-hour exposures to a concentration of 200,000 ppm, a single 16-hour exposure or repeated 8-hour exposures to the same concentration proved to be lethal. After twenty-one 8-hour exposures to concentrations ranging from 142,000 to 150,000 ppm, dogs were alive but showed blood changes, incoordination, and convulsions (Yant 1933). One of 12 dogs experienced serious cardiac arrhythmia after exposure to a 25,000 ppm concentration of dichlorotetrafluoroethane and an injection of epinephrine (Reinhardt, Azar, Maxfield 1971). Another study reported that exposure to a dichlorotetrafluoroethane concentration of 50,000 to 800,000 induced cardiac sensitization in dogs (Reinhardt, Azar, Maxfield et al. 1971; Mullin, Azar. Reinhardt et al. 1972). Chronic exposure of rats to 10,000 ppm and dogs to 5,000 ppm for 6 hours/day for 90 days caused no clinical, biochemical, or histologic changes visible at autopsy (Leuschner et al. 1983, in Proctor, Hughes, and Fischman 1988, p. 193).

In humans, exposure to dichlorotetrafluoroethane vapor causes mild and transient central nervous system damage (Gosselin, Smith, and Hodge 1984, p. II–160). Contact with the cryogenic liquid can cause frostbite or burns of the skin or eyes (Proctor, Hughes, and Fischman 1988, p. 193).

Based on this evidence in humans and animals, OSHA primarily concludes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing eye and respiratory irritation and central nervous system depression. OSHA believes that an 8-hour TWA PEL of 1000 ppm will substantially reduce these risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. ETHYLENE GLYCOL DINITRATE CAS: 628–96–6; Chemical Formula:

CH₂NO₃CH₂NO₃ H.S. No. 1170 NITROGLYCERIN CAS: 55-63-0; Chemical Formula: CH2NO3CHNO3CH2NO3 H.S. No. 1290

OSHA's current exposure limits for ethylene glycol dinitrate (EGDN) and nitroglycerin (NG) in construction and maritime are both 0.2 ppm (1.0 mg/m3) as ceiling concentrations. These limits also bear skin notations. There are no PELs for these substances in agriculture. The ACGIH TLV®s for EDGN and NG are 0.05 ppm (0.3 mg/m3) as 8-hour TWAs, with skin notations. OSHA is proposing limits for EDGN and NG in construction, maritime, and agriculture of 0.1 mg/m3 as 15-minute STELs and is retaining the skin notations; these limits are based on NIOSH's recommended limits. These are the limits recently established for these substances in general industry.

EDGN is an oily, yellowish, explosive liquid, and NG is a pale yellow, viscous liquid. EDGN and NG are frequently encountered together in dynamite and other high explosives. EDGN is used exclusively as an anti-freezing agent in such explosives. NG is also used in rocket propellant (HSDB 1989), as a medication for cardiovascular disease, and in veterinary medicine to treat

asthma in dogs (Merck 1983).

Both NG and EDGN have moderate acute toxicity when administered orally to rats or mice; the oral LD50s for NG in rats and mice are 105 and 115 mg/kg. respectively, and the oral LDso for EDGN in rats is 616 mg/kg (RTECS 1990). Animals given NG or EDGN orally exhibit marked cardiovascular and other symptoms, including decreased blood pressure, tremors, ataxia, lethargy, altered respiration, cyanosis, prostration, convulsions, and death from either respiratory or cardiac arrest. In addition, both NG and EDGN produce methemoglobinemia in animals following acute exposure. Chronic exposure (2 ppm, 8 hours/day, for 1000 days) of cats to EDGN caused anemia; fatty changes in the heart, liver, and kidney; and hyperplasia of the bone marrow (HSDB 1989). Reproductive and developmental effects have been noted in rats exposed to NG by skin painting (2400 mg/kg for 30 days) and intraperitoneal injection (11 or 220 mg/ kg during days 7-17 of pregnancy) (RTECS 1990).

The cardiovascular effects seen in animals have also occurred in humans; low-level exposure to NG or EDGN causes headache (due to vasodilation). dizziness, nausea, skin rash, and methemoglobinemia. More severe exposure results in hypotension, flushing, palpitations, delirium, and

central nervous system depression. Consumption of alcohol can aggravate these effects. Exposure to NG or EGDN can also result in persistent tachycardia and reduced pulse pressure (Carmichael and Lieben 1963).

Workers exposed to NG or EDGN for a period of time (i.e., 6 to 10 years) may develop organic nitrate dependence, which causes severe and life-threatening symptoms to appear after periods of non-exposure (such as after a weekend). In such cases, affected individuals complain of sudden chest pains that resemble angina pectoris and then die suddenly, often before treatment can be administered (Carmichael and Lieben 1963; Proctor, Hughes, and Fischman

1988, p. 247, 376).

A number of investigations provide information on the exposure levels that result in adverse effects in humans. Trainor and Jones (1966/Ex. 1-107) reported that exposure to EGDN:NG at a level of 0.7 mg/m3 for 25 minutes was sufficient to produce decreased blood pressure and a slight headache in humans. These authors also reported that workers at a munitions plant developed headaches when exposed to EGDN:NG concentrations between 0.1 and 0.53 mg/m3 (0.36 mg/m3 average). Morikawa, Muraki, Ikoma et al. (1967/ Ex. 1-55) found that workers in an explosives plant exposed to low concentrations of EGDN:NG (0.066 ppm (approximately 0.5 mg/m3) was the highest average level) had a much higher incidence of abnormal pulse waves than did controls (143 out of 1,271 versus 0 out of 175). Abnormal pulse waves often indicate a clinically significant defect in the functioning of the heart and/or circulatory system (Braunwald 1978/Ex. 1-1001).

In its criteria document for NG and EGDN, NIOSH (1978h/Ex. 1-234) refers to a report of a dynamite worker who died when exposed to EGDN:NG concentrations between 0.3 and 1.4 mg/ m3, as well as to another report of two workers who died suddenly following exposure to EGDN:NG at concentrations ranging from 1.7 to 2.7 mg/m3. NIOSH (1978h/Ex. 1-234) observed that skin absorption may have contributed significantly to the exposures causing

these deaths.

During the rulemaking for general industry, OSHA received several comments (Exs. 3-661, 8-66, 121, 190, and 154) on the strength of the evidence and significance of the adverse effects associated with exposure to EGDN and NG. Specifically, these commenters questioned the relevance of the toxicologic data discussed above in light of the improved working conditions prevailing today in NG/EDGN

manufacturing plants. In addition, the Institute of Makers of Explosives (IME) asserted that "headaches are transitory phenomena which pose no significant health risk" (Ex. 190, p. 5).

OSHA does not share the IME's view of the significance of chemically induced headaches. The Agency believes that such headaches impair performance. cause pain and suffering, affect the safety of the victim and his or her coworkers, and contribute to absenteeism. In the case of EGDN:NG-induced headaches, however, headaches have a greater meaning: They are an early warning of vasodilation, an indicator of systemic toxicity. OSHA also believes that the report of an EGDN:NG-induced death in an explosives manufacturing facility is both convincing and troubling. The Trainor and Jones (1966/Ex. 1-107) study, the NIOSH criteria document (1978h/Ex. 1-234), and the Morikawa. Muraki, Ikoma et al. (1967/Ex. 1-55) study indicate that the health effects associated with exposure to very low levels of EGDN:NG (i.e., in the range of 0.1 to 1.4 mg/m³) are acute, may occur after brief exposures, and have been shown to be lethal.

According to NIOSH (Ex. 150), the 15minute 0.1-mg/m3 limits being proposed for these substances will protect against "angina pectoris, other signs and symptoms of cardiac ischemia or heart damage, and against sudden death * * * since all of these * * * seem to be related to compensatory vasoconstriction induced by repeated exposure to NG or EGDN' (Ex. 150). NIOSH also reports that a preliminary study of mortality resulting from heart disease and other causes among NG workers by Reeve, Bloom, Rinsky, and Smith (1983a and 1983b) suggests an association between NG exposure and cardiovascular disease mortality; at the facilities where this increase in cardiovascular disease occurred, exposures were being maintained near or below 0.02 ppm (0.2 mg/m³) (Ex. 150).

Hypotension and headache have been observed in populations exposed to EGDN:NG at levels below 0.5 mg/m3 for brief periods (25 minutes), and fatalities have occurred after EGDN:NG exposures at concentrations between 0.3 and 1.4 mg/m3, in one instance, and between 1.7 and 2.7 mg/m3, in another.

These substances present severe explosive hazards as well. Methods to reduce exposures to EGDN:NG must take this factor into account. OSHA has considered the explosion factor in various actions it has taken in regard to general industry, such as extending compliance periods. OSHA is not aware of these problems in construction, maritime, or agriculture; therefore, the Agency requests comment on whether such problems exist in these sectors.

OSHA's current standard for these substances in construction and maritime is 0.2 ppm (1.2 mg/m3 for EGDN and 2.0 mg/m3 for NG); since worker deaths have occurred at or near this level. OSHA is proposing short-term limits for EGDN and NG of 0.1 mg/m3, with skin notations, for these substances in these two sectors and in agriculture. OSHA preliminarily concludes that these limits are necessary to prevent fatalities and to protect workers in these sectors against the significant risks of vasodilation and cardiac effects, which are considered material impairments of health. Because EGDN:NG is readily absorbed through the skin and can produce systemic effects by this exposure route, OSHA is retaining the skin notations for both substances in construction and maritime and is proposing one in agriculture. In addition, promulgation of these limits will make OSHA's PELs for these substances consistent across all regulated sectors. **FLUOROTRICHLOROMETHANE**

(TRICHLOROFLUOROMETHANE) CAS: 75-69-4; Chemical Formula: CCl₃F

H.S. No. 1180

Fluorotrichloromethane (trichlorofluoromethane), also known as FC-11, is a member of a large family of chemicals, the chlorofluorocarbons.

OSHA has no PEL for this substance in construction, maritime, or agriculture.

The ACGIH TLV* for FC-11 is 1000 ppm as an instantaneous ceiling. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing a ceiling PEL of 1000 ppm for fluorotrichloromethane in construction, maritime, and agriculture. This is the limit recently established in general industry.

FC-11 is a colorless, nonflammable, low-boiling liquid or gas (depending on temperature). Its primary uses are as an aerosol propellant, a refrigerant, a fire extinguisher, a solvent and degreasing agent, and a blowing agent in the production of polyurethane foam (HSDB)

1985).

The lowest lethal inhalation dose of FC-11 in 50 percent of mice (LC₅₀) is 100,000 ppm for 30 minutes (RTECS 1990). Before death, these mice developed cardiac arrhythmias, and dogs inhaling 25,000 ppm had decreased myocardial function (Aviado and Belej 1975). Monkeys were the most sensitive of the species tested to FC-11's cardiotoxic effects (Clayton and Clayton 1981, p. 3085); Drinking Water and Health, National Research Council

1977). Exposure to 5000 ppm FC-11 has induced cardiac sensitization and arrhythmia in dogs that were intravenously injected with epinephrine (Reinhardt, Azar, Maxfield, Smith, and Mullin 1971/Ex. 1-78).

Acute overexposure to FC-11 by inhalation has caused cardiac sensitization (arrhythmia) or bronchial constriction and death in exposed humans (Drinking Water and Health, National Research Council 1977). Volunteers exposed to 1000 ppm for 8 hours/day, 5 days/week for 18 exposure episodes evidenced no changes in their electrocardiograms or pulmonary function tests (Clayton and Clayton 1981, p. 3081). Slowed heart rate is the usual response in humans inhaling low (not further specified) concentrations of FC-11 (Clayton and Clayton 1981, p. 3085).

The cardiac sensitization exhibited by FC-11-exposed individuals is an acute effect. OSHA believes that, in the absence of a limit, workers in construction, maritime, and agriculture could be exposed to sufficiently high concentrations of FC-11 to sensitize the heart to sympathomimetic amines; OSHA considers this effect to be a material impairment of health. Accordingly, OSHA preliminarily concludes that workers in these sectors are at significant risk of experiencing arrhythmia and the other exposurerelated effects of FC-11 and that the proposed 1000-ppm ceiling limit will substantially reduce this significant risk. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

PENTACHLOROPHENOL CAS: 87-86-5; Chemical Formula:

C₆HCl₅O H.S. No. 2124

In general industry, construction, and maritime, OSHA's permissible exposure limit for pentachlorophenol is 0.5 mg/m3 as an 8-hour TWA; this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. There is no limit in agriculture. The ACGIH has a TLVº-TWA of 0.5 mg/m3. with a skin notation, for pentachlorophenol. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing to establish an 8-hour TWA PEL of 0.5 mg/m3, and a skin notation, for pentachlorophenol in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Pentachlorophenol is a colorless to light brown solid with a phenol-like odor and a pungent taste. It is used as a chemical intermediate, and as a herbicide, fungicide, molluscicide, and wood preservative (ACGIH 1986, p. 461: Hawley's 1987, p. 881). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Pentachlorophenol causes eye, skin, and respiratory tract irritation, hyperpyrexia, increased metabolic rate, and circulatory effects in humans and animals; in animals it is also fetotoxic. The oral LD50s in various species are 27 mg/kg in rats, 117 mg/kg in mice, and 168 mg/kg in hamsters, respectively (RTECS 1990). In rats, the dermal LDso is 95 mg/kg; the lowest lethal dermal dose in rabbits is 40 mg/kg (RTECS 1990). The LC50 in mice is 225 mg/m3; in rats, it is 355 mg/m3 (RTECS 1990). When 10 mg of this substance was placed on the skin of rabbits, it caused mild irritation (RTECS 1990). Acutely poisoned animals showed accelerated respiration, elevated body temperature, tachycardia, and neuromuscular weakness before dying of cardiac failure; rigor mortis is instantaneous (Deichmann et al. 1942, in IARC 1979, Vol. 20, p. 314). Animal studies have shown that the immune system is sensitive to pentachlorophenol exposure (Kerkvliet, Baecher-Steppan and Schmitz et al. 1982). Mice given 50 to 500 ppm technical grade pentachlorophenol in their diets showed signs of greatly reduced immunocompetence, expressed as an increased susceptibility to the growth of transplanted tumors (Kerkvliet, Baecher-Steppan and Schmitz et al. 1982). Thirty male rats given 20 mg/l of pentachlorophenol showed neurochemical effects after 3 to 14 weeks of exposure (National Research Council 1986, in HSDB 1989). In a 2-year study, rats were given oral doses of 10 and 30 mg/kg/day of pentachlorophenol; the animals in the high-dose group showed decreased body weights, increased serum glutamic-pyruvate transaminase activity, and increased urinary specific gravity (Schwetz et al. 1978, in Clayton and Clayton 1981, p. 2607). Hamsters given daily oral doses of 1.25 mg/kg pentachlorophenol from days 5 to 10 of gestation had an increase in fetal deaths and resorptions; the noeffect level was 2.5 mg/kg/day (National Research Council 1986, in HSDB 1989). Pentachlorophenol caused signs of fetotoxicity, including resorptions, subcutaneous edema, dilated ureters, and anomalies of the skull, ribs, and vertebrae, in the offspring of rats dosed orally at a level of 5 to 50 mg/kg per day

(Schwetz, Keeler and Gehring et al. 1974). In an NTP (1989) bioassay, two pentachlorophenol mixtures (technical grade and Dowicide EC-7) were tested for carcinogenicity in male and female B6C3F1 mice. Groups of 50 male and 50 female mice were fed diets containing 100 or 200 ppm technical grade pentachlorophenol, or 100, 200, or 600 ppm Dowicide EC-7, for 2 years. The study found clear evidence of carcinogenicity among male mice fed either mixture, as shown by increased incidences of adrenal medullary and hepatocellular neoplasms, and among female mice fed Dowicide EC-7, as shown by increased incidences of adrenal medullary and hepatocellular neoplasms and hemangiosarcomas. The study found some evidence of carcinogenicity among female mice fed technical grade pentachlorophenol, as evidenced by increased incidences of hemangiosarcomas and hepatocellular neoplasms.

In humans, exposure to pentachlorophenol dust and mist concentrations in excess of 1 mg/m3 causes pain and irritation of the nose and throat and violent sneezing and coughing (Deichmann and Keplinger 1981; Demidenko 1969, in ACGIH 1986, p. 461). The signs and symptoms of pentachlorophenol poisoning may include profuse diaphoresis, hyperpyrexia, tachycardia, tachypnea, weakness, nausea, vomiting, abdominal pain, headache, anorexia, progressive coma, and death [Wood, Rom, White, and Logan 1983). Acute poisoning also can affect renal and hepatic function (Wood, Rom, White, and Logan et al. 1983). The lowest lethal oral dose reported in humans is 29 mg/kg (RTECS 1990). A worker experienced exfoliation of the epidermal layer of the hands 1 to 2 days after handling a 20 percent sodium pentachlorophenate solution; recovery occurred within 5 days (Nomura 1953, in Hayes 1982, p. 475). After washing a paint brush in a solvent containing 0.4 percent pentachlorophenol, a worker's hands became painful and red; the pain lasted for about 2 hours (Hayes 1982, p. 475). A 32-year-old white male exposed to lumber pretreated with pentachlorophenol suffered from chloracne characterized by many small yellow/white papules over most of his body; the condition improved after 6 weeks of treatment (Cole, Stone, Gates, and Culver 1986). Five incidents of poisoning, including two fatalities, have been reported in workers from two small wood preservative plants; symptoms included fever, severe hyperpyrexia, increased anion gap, and

renal insufficiency (Wood, Rom, White, and Logan 1983). Chronic exposure to this substance is associated with an increase in conjunctivitis, chronic sinusitis, bronchitis, polyneuritis, and dermatitis (Proctor, Hughes, and Fischman 1988, p. 398). Repeated exposure to commercial pentachlorophenol caused aplastic anemia in four individuals, pure red cell aplasia in two people, and subsequent Hodgkin's disease and acute leukemia in two of these individuals (Roberts 1983).

Based on this evidence in humans and animals, OSHA preliminarily concludes that pentachlorophenol causes sensory irritation and systemic toxicity. OSHA believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that establishing a TWA limit of 0.5 mg/m3, and a skin notation, is necessary to significantly reduce these risks of material health impairment. In addition, promulgation of this PEL and the skin notation will make OSHA's limit for this substance consistent across all regulated sectors. SODIUM AZIDE

CAS: 26628–22–8; Chemical Formula:

H.S. No. 1364

There is no current OSHA PEL for sodium azide in construction, maritime, or agriculture. The current ACGIH TLV* for this substance is 0.1 ppm as an instantaneous ceiling. NIOSH has no REL but concurs (Ex. 8–47, Table N1) with the limits being proposed. OSHA is proposing a ceiling limit of 0.1 for sodium azide as HN3 and 0.3 mg/m³ as a ceiling limit for sodium azide NAN3, both with skin notations. These are the limits recently established in general industry.

Sodium azide is a colorless, crystalline solid. It is used as a chemical intermediate; an herbicide, fungicide, nematocide, and soil fumigant; in automobile air bags; and to decompose

nitrites (HSDB 1989).

Sodium azide is a material of high acute toxicity that acts by direct vasodilation. The oral LD50s for rats and mice have been reported to be 27 mg/kg and 19-27 mg/kg, respectively (RTECS 1989). There have been several reported cases of accidental human poisonings involving ingestion of mg quantities of sodium azide; symptoms reported from these cases have included nausea, headaches, sweating, faintness, tachycardia, hypotension, and hyperventilation. Sodium azide is known to produce hypotension in laboratory animals as well as humans. An intravenous dosé of 1 mg/kg was

reported to lower blood pressure in cats (Graham 1949/Ex. 1-109). In the 1950s, the medicinal usefulness of sodium azide as a hypotensive agent was tested in 30 hypertensive patients. Their hypertension was reduced, but observed side effects included headaches; in addition, 20 of 30 patients developed increased sensitivity to sodium azide. necessitating a reduction in the dose (Black, Zweifach, and Speer 1954/Ex. 1-163). Hicks (1950) reported that repeated intraperitoneal injections of 5 to 10 mg/ kg in rats caused demyelination of the nerve fibers of the central nervous system. Alben and Fager (1972) showed that sodium azide formed strong complexes with hemoglobin and blocked oxygen transport in the blood.

In addition to these effects, sodium azide has been reported to cause testicular damage in rats given intraperitoneal injection of doses sufficient to cause intoxication, Reported doses given to monkeys have caused damage to the central nervous system, resulting in blindness and attacks of rigidity.

Acute inhalation by humans of hydrazoic acid vapor (which forms when sodium azide contacts water) results in lowered blood pressure, eye irritation, bronchitis, headache, weakness, and collapse (Fairhall et al. 1943/Ex. 1–130; Graham 1949/Ex. 1–109). The exposure levels that produce these effects were not reported by these authors. Haas and Marsh (1970/Ex. 1–121) reported that exposure to concentrations of hydrazoic acid vapor as low as 0.5 ppm "cause[d] some discomfort to laboratory personnel."

Because of its hypotensive effect in humans, OSHA preliminarily concludes that ceiling limits of 0.1 ppm (measured as HN₃) and 0.3 mg/m³ (measured as NaNal should be established for sodium azide to reduce the significant risk of cardiovascular and irritation effects potentially posed to construction. maritime, and agriculture workers at the levels permitted by the absence of an OSHA limit. To reduce this significant risk substantially, OSHA is proposing to establish these ceiling limits for sodium azide, as well as a skin notation. OSHA believes that the skin notation will alert employers to the fact that sodium azide readily penetrates intact skin and that dermal exposure can contribute significantly to overall worker exposure. In addition, promulgation of these limits will make OSHA's PELs for these substances consistent across all regulated sectors.

1,1,2-TRICHLORO-1,2,2-TRIFLUOROETHANE CAS: 76-13-1; Chemical Formula: CCl₂FCClF₂ H.S. No. 1403

1,1,2-Trichloro-1,2,2-trifluoroethane (FC-113) is a member of the chlorofluorocarbon family. The current OSHA PEL for this substance in construction and maritime is an 8-hour TWA of 1000 ppm. The ACGIH has an 8hour TLV*-TWA of 1000 ppm and a 15minute STEL of 1250 ppm for FC-113. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limits being proposed. The Agency proposes to retain the TWA limit and to add a 1250 ppm STEL in construction and maritime. OSHA has no PEL for this substance in agriculture, and proposes adding a 1000 ppm 8-hour TWA PEL and a 1250 ppm STEL for FC-113 in agricultural workplaces. These are the limits recently established for this substance in general industry.

FC-113 is a colorless, noncombustible liquid. It is used as a chemical intermediate in the production of polychlorotrifluoro-ethylene resins and polychlorotrifluoro-ethylene-vinylidine, as a fire extinguishant and as a foam blowing agent, a drying agent, a degreasing solvent, and a dry cleaning solvent. FC-113 is also used as a

refrigerant.

FC-113 has a low potential for acute lethality; the 4-hour LC₅₀ in rats has been reported to range from 52,000 to 68,000 ppm (ACGIH 1986). In experimental animals, the principal effects of exposure to FC-113 include tachycardia, myocardial depression, hypotension, and cardiac sensitization. These effects have been seen in monkeys and dogs exposed to 25,000-50,000 ppm (HSDB 1989). Exposure of animals to high concentrations (i.e., 12,000 ppm) has also been found to cause central nervous system depression, respiratory irritation, and mild liver changes (ACGIH 1986).

Cardiac sensitization has been found to result from lower, short-term exposures. Reinhardt, Mullin, and Maxfield (1973/Ex. 1-114) observed that 10 out of 29 dogs exposed to 5000 ppm FC-113 for 5 minutes and simultaneously injected with epinephrine developed serious arrhythmias. Similar experiments, in which the dogs were exposed to 2000 to 2500 ppm of this substance for longer periods of time (from 30 minutes to 6 hours) and simultaneously administered epinephrine, resulted occasionally in arrhythmia (Aviado 1975). However, when the experiment was repeated using four 6-hour exposures to 1000 ppm in conjunction with an injection of epinephrine, no arrhythmias were

observed. Cardiac sensitization has also been reported in monkeys exposed to 2000 ppm FC-113 for 6 hours (EPA 1983).

A study by Stopps and McLaughlin (1967/Ex. 1-122) of human volunteers revealed that exposure to 2500 ppm FC-113 for 1.5 hours resulted in impairment of psychomotor performance (described as lethargy and inability to concentrate). This effect was not observed at concentrations below 2500 ppm. Within the first one-half to one hour of exposure to 2500 ppm or more, subjects reported subjective sensations including loss of concentration, a tendency to somnolence, and a feeling of "heaviness" in the head. OSHA believes that the results of the Stopps and McLaughlin (1967/Ex. 1-122) study described above demonstrate that FC-113 can induce subjective effects in humans on short-term exposure. Thus, OSHA preliminarily concludes that a STEL is necessary to prevent these effects among construction, maritime, and agriculture workers. The proposed STEL includes a small safety factor below the human NOEL to account for variabilities in toxic responses.

The evidence described above indicates that FC-113 can exert toxic effects at levels of exposure comparable to the levels that are permitted by excursions above the current OSHA TWA limit of 1000 ppm; OSHA believes that such levels pose a significant risk of cardiac sensitization to exposed workers. The Agency considers the cardiac sensitization induced by FC-113 a material impairment of health and functional capacity. OSHA therefore preliminarily concludes that a STEL of 1250 ppm will provide a wider margin of safety against cardiac sensitization and will reduce the risk of impaired psychomotor performance by limiting the potentially high, short-term exposures permitted by the 1000 ppm 8hour TWA limit alone. Thus, OSHA proposes limits of 1000 ppm TWA and 1250 ppm STEL for 1.1,2-trichloro-1,2,2trifluoroethane in construction, maritime, and agriculture to substantially reduce the significant risks associated with exposure to this substance. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

Preliminary Conclusions. Of all the physiological systems, the cardiovascular system is especially vulnerable to occupational hazards because cardiovascular diseases are already so prevalent in our society. According to Levy (1985/Ex. 1–210), "an estimated 40 million Americans have some form of cardiovascular disease." The major risk factors, as revealed by

epidemiology, are age, male sex, hypertension, cigarette smoking, the existence of low-density and highdensity plasma lipoproteins, cholesterol. and diabetes (Levy 1985/Ex. 1-210). Many American workers exposed to the chemicals grouped on the basis of their cardiovascular effects have one or more of these risk factors and are therefore particularly susceptible to exposure to cardiovascular toxicants. Although the precise interactions among these risk factors and exposures to cardiovascular toxins are difficult to demonstrate with accuracy, few would argue that they do not occur.

OSHA preliminarily concludes that the potential for cardiovascular system damage associated with exposure to these cardiac sensitizers, vasodilators, and atherosclerosis-causing substances poses a significant risk to employees in a broad range of workplaces. The effects experienced by exposed workers include arrhythmia, low blood pressure. stroke, and blockage of the flow of blood to the myocardium. Reducing the exposure limits for these cardiovascular toxins from levels where such effects could occur to concentrations where their occurrence is unlikely will substantially reduce these risks. OSHA believes that the health evidence for these cardiovascular toxins forms a reasonable basis for proposing new or revised limits. At the time of the final rule. OSHA will establish new or revised limits for these substances if the Agency determines that such limits will substantially reduce significant risk.

8. Substances for Which Proposed Limits Are Based on Avoidance of Systemic Toxicity

Introduction. For a number of substances, OSHA's proposed limits are based primarily on evidence that exposure is associated with general systemic toxicity. This group of substances is unique among the groupings discussed in this preamble in that no single organ system can be identified as the target of low-dose exposure to these chemicals. Instead, these substances have been shown either to affect several organ systems simultaneously or to cause a variety of nonspecific adverse signs and symptoms that are indicative of general toxicity.

The 73 substances belonging to this group and their CAS numbers, HS numbers, 1987–1988 ACGIH TLV*s and NIOSH RELs are shown in Table C8–1. The current PELs for these substances in construction and maritime are shown in the second column of Table C8–1, and the limits being proposed in construction, maritime, and agriculture

are shown in the right-hand column of the table. Promulgation of the proposed limits in construction, maritime, and agriculture will make the PELs for these

substances consistent across all OSHA-regulated sectors.

* OSHA's PELs do not currently apply in agriculture; OSHA's TWA limits are for 8-hour exposures; its STELs are for 15 minutes unless otherwise specified; and its ceilings are peaks not to be exceeded for any end of time.

** The ACGIH TLV®-TWA is for an 8-hour exposure; its STELs are 15-minutes limits not to be exceeded more than 4 times in any working day, with a minimum of 60 minutes between successive STEL exposures; and its ceilings are peaks not to be exceeded for any period of time. An Action and the action of time are for 10 hour/day, 40 hour/way, 40 hour/way, 40 hour/way, 40 hour/way, 40 hour/way, 40 hour/way, and its ceilings are peaks not to be exceeded for any period of time unless a duration is specified in parentheses.

**NIOSH considers this substance a potential occupational carcinogen and recommends that exposures be reduced to the lowest feasible concentration.

Description of the Health Effects. For each substance included in this grouping, limits have been proposed to protect workers in construction, maritime, and agriculture against a variety of adverse exposure-related effects that are manifested at multiple target organ sites. In some instances, the nature of the toxic effects associated with exposure is well-defined and clearly understood (for example, CNS depression, histological organ changes, embryotoxicity, methemoglobinemia, conjunctivitis, liver and kidney damage, testicular damage). The effects of exposure to other substances in this group, however, have been demonstrated only by such nonspecific indicators as dizziness, respiratory irritation, hematuria, chest tightness, weight loss or decreased rate of weight gain, lethargy, loss of appetite, nervousness, or gastrointestinal disturbances. Although the specificity of the systemic effect caused by exposure to the substances in this group may vary, all of these substances have been shown to be biologically active in mammalian species, to interfere significantly with biological processes, and to impair normal organ function.

Table C8-2 summarizes the toxic exposure-related effects reported for these substances in humans and experimental animals; this evidence supports the limits being proposed for these substances. This table shows the variety of adverse health effects that adoption of the proposed rule's limits will minimize or prevent. The table also shows that, for the vast majority of substances in this group, the risks of exposure have been defined in studies of humans or animals and are known to include respiratory effects, neurological effects, adverse effects on the reproductive system, organ damage, hematopoietic effects, sensitization, and mucosal irritation. All of these effects are indicative of generalized systemic effects rather than localized effects occurring at the site of chemical contact, and all of them are considered material impairments of health within the meaning of the Act.

Dose-Response Relationships and Systemic Effects. As Table C8–2 shows, adverse toxic reactions have been reported to occur in humans for more than half of the substances in this group; for these substances, it has thus been established conclusively that exposure is associated with adverse health effects

in humans. Experimental animal data comprise the principal evidence for the toxicologic action of the remaining substances. As is the case for many substances for which limits are being proposed in this rulemaking, apparent no-observed-effect levels, supplemented by the use of appropriate margins of protection, provide the basis for setting the limits. The systemic effects caused by exposure to substances in this group appear to follow a no-observed-effect (NOE) dose-response pattern. That is, as intensity and/or duration of exposure decreases, the severity of the effect on organ systems also decreases until a point is reached (the NOE level) where there is no detectable effect, at least at observable levels, on organ systems. Noeffect exposure levels have been identified in humans and animals for several of the substances in this group; where no-effect levels have been identified (i.e., for diglycidyl ether and phenylphosphine), they have provided the primary basis for the proposed limits. In instances where no-effect levels have not been reported (e.g., for n-butyl glycidyl ether, trimethylbenzene, and acetylsalicylic acid), OSHA has used safety factors and expert judgment to derive an NOE value.

tory irritation; hematopoietic effects.

The following discussions describe OSHA's preliminary findings for these systemic toxicants and present a summary of the material impairments of health potentially associated with exposure to these substances.

ACETONITRILE

CAS: 75–05–8; Chemical Formula:

CH₃CN H.S. No. 1005

OSHA's occupational exposure limit for acetonitrile in construction and maritime is 40 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a 40 ppm TLV*-TWA and a 60-ppm TLV*-STEL, in addition to a skin notation. NIOSH has a TWA-REL of 20 ppm for acetonitrile. OSHA is proposing to retain the 40-ppm 8-hour TWA in construction and maritime, to add a STEL of 60 ppm for 15 minutes in these two sectors, and to extend both limits to agriculture. These are the limits recently established for acetonitrile in general industry.

Acetonitrile is a colorless liquid with an aromatic odor. It is most widely used in industry as a specialty solvent and

chemical intermediate.

In animal studies, acetonitrile has been found to be embryotoxic and teratogenic in rodents exposed to levels sufficiently high to cause maternal toxicity (Berteau, Levinskas, and Rodwell 1982/Ex. 1–179; Willhite 1983/Ex. 1–43). A 13-week inhalation study conducted by the National Toxicology Program [Hazelton Leboratories, Inc. 1983, as cited in ACGIH 1986/Ex. 1–3, p. 8) found pathological changes in the liver and some blood changes in mice and rats exposed to concentrations of 400 ppm acetonitrile.

The human evidence describing the toxic effects associated with exposure to acetonitrile consists of a report by Pozzani, Carpenter, Palm et al. (1959/Ex. 1–106), who exposed human subjects to acetonitrile vapor, and a case report by Amdur (1959/Ex. 1–143), who described a poisoning incident involving acetonitrile. None of three subjects

exposed to 40 ppm for 4 hours reported any adverse responses during the exposure period, but one subject experienced tightness of the chest a few hours after termination of exposure, as well as a cooling sensation in the lungs the following day. None of the subjects had elevated blood cyanide levels; one subject showed a slightly elevated urinary thiocyanate level. Pozzani et al. (1959/Ex. 1-106) also exposed two subjects to 80 ppm and 160 ppm of acetonitrile for 4 hours. When exposed to 80 ppm, subjects reported no adverse response; however, at 160 ppm, one subject experienced slight flushing of the face and chest tightness a few hours after exposure (Pozzani, Carpenter, Palm et al. 1959/Ex. 1-106).

In addition to the Pozzani et al. (1959/ Ex. 1-106) study, NIOSH (1978g/Ex. 1-262) cites a report by Amdur (1959/Ex. 1-143), who investigated an incident in which 16 painters became ill (with one death) after using an acetonitrilecontaining material in a confined space. Amdur (1959/Ex. 1-143) reported no further incidents after adequate ventilation was installed and acetonitrile levels were maintained at about 17 ppm. NIOSH concluded that exposure to 40 ppm produced only minimal effects and that no observable effects were produced at 17 ppm (NIOSH 1978g/Ex. 1-262, p. 97)

Based on this evidence, OSHA preliminarily concludes that long-term exposure to 40 ppm causes no or only minimal effects and that a short-term limit of 60 ppm will provide protection against the facial flushing and chest tightness experienced by workers exposed for several hours to levels above this concentration. In construction and maritime, OSHA is therefore proposing to retain the 8-hour TWA of 40 ppm for acetonitrile and to add a STEL of 60 ppm; OSHA is also proposing to extend both limits to agriculture. The Agency preliminarily concludes that the proposed limits will prevent the significant risk of acute

illness (and, in one case, death) observed in workers exposed to excessive short-term levels of acetonitrile; the Agency believes that these health effects clearly constitute material impairments of health. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

ACETYLSALICYLIC ACID (ASPIRIN)
CAS: 50-78-2; Chemical Formula:
CH₅COOC₆H₄COOH

H.S. No. 1006

In construction, maritime, and agriculture, there is no PEL for acetylsalicylic acid. The ACGIH has a TLV* of 5 mg/m³ for this substance as an 8-hour TWA. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing a 5 mg/m³ 8-hour TWA PEL for acetylsalicylic acid in construction, maritime, and agriculture. This is the limit recently established in general industry.

Acetylsalicylic acid is a white crystal or powder that is essentially odorless and has a slightly bitter taste. It is used in medicine as an anti-inflammatory drug, an anti-pyretic, and as an analgesic (Hawley's 1987, p. 103).

The work of O'Brien (1968/Ex. 1-47) reports that a normal therapeutic dose of 600 mg aspirin will interfere with platelet aggregation in subjects exposed for a period of 5 days or more. Hart (1947/Ex. 1-137) also reported that 150 mg is the smallest oral dose of acetylsalicylic acid that will produce this effect. Unpublished data from the Dow Chemical Company (cited in ACGIH 1986/Ex. 1-3, p. 10) indicate that exposure to aspirin concentrations exceeding 100 mg/m3 are tolerated except for occasional skin irritation. However, no data are available on the long-term effects on organ systems of inhalation exposure to aspirin. Secondary sources report that aspirin is

industry.

an acute irritant to the gastric mucosa

and respiratory tract.

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 5 mg/ m3 for acetylsalicylic acid in the construction, maritime, and agriculture sectors. The Agency preliminarily concludes that this limit will protect workers in these sectors from experiencing adverse blood effects and gastric and respiratory irritation, which are potentially associated with exposure to this substance in the workplace. OSHA believes that these effects constitute material health impairments and that the proposed limit is necessary to substantially reduce these risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. ALUMINUM (WELDING FUMES) CAS: 7429-90-5; Chemical Formula: Al H.S. No. 1019

OSHA has no permissible exposure limit for aluminum welding fumes in the construction, maritime, or agriculture industry. The ACGIH TLV*-TWA for these fumes is 5 mg/m³. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing a TWA-PEL for aluminum welding fumes of 5 mg/m³, measured as aluminum. This is the limit recently established for these fumes in general

The proposed PEL addresses the aluminum fume that is released in the welding process; this limit is being proposed to keep total aluminum particulate concentrations low enough to prevent aluminum particle accumulation in the lungs of exposed workers. However, to the extent either that other toxic substances or materials are released in the welding process or that conditions are conducive to the formation of toxic gases, employers are required to pay attention to the permissible exposure limits for these substances as well. For example, in appendix B of the 1987-88 Threshold Limit Values and Biological Exposure Indices (ACGIH 1987/Ex. 1-16), the ACGIH states that "reactive metals and alloys such as aluminum and titanium are arc-welded in a protective, inert atmosphere such as argon. These arcs create relatively little fume, but an intense radiation which can produce ozone" (ACGIH 1987/Ex. 1-16, appendix B, p. 42). In such an instance, employers would be required to meet any ozone limits in effect (PELs of 0.1 ppm TWA and 0.3 ppm STEL are being proposed for ozone) as well as the PEL for aluminum welding fumes.

The ACGIH states that "most welding, even with primitive ventilation, does not produce exposures inside the welding helmet above 5 mg/m³. That which does * * * should be controlled" (ACGIH 1987/Ex. 1–16, appendix B, p. 43). In those rare instances where internal helmet exposures do exceed 5 mg/m³, employees are at risk from the irritant effects of hot metal fumes, which are deposited in the lung deeply and accumulate there.

Because workers in construction, maritime, and agriculture who are exposed to arc welding fumes have previously not been protected by a permissible exposure limit, OSHA is proposing a PEL of 5 mg/m3 TWA for these fumes (measured in the breathing zone of the welder); the details of the appropriate positioning of the sampler should be determined on the basis of guidance in the Field Operations Manual (OSHA 1984). The Agency preliminarily concludes that the proposed limit will protect welders and other workers in the vicinity of the welding from experiencing the significant irritation potentially associated with inhalation of these fumes. OSHA believes that the respiratory irritation caused by exposure to these fumes constitutes a material health impairment and that the proposed PEL is necessary to substantially reduce this significant risk. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

2–AMINOPYRIDINE CAS: 504–29–0; Chemical Formula: $C_5H_6N_2$ H.S. No. 2004

In general industry, construction, and maritime, OSHA's current permissible exposure limit for 2-aminopyridine is 0.5 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV® of 0.5 ppm as an 8-hour TWA for this substance; NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 0.5 ppm for 2-aminopyridine in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all regulated sectors.

2-Aminopyridine is a moderately flammable solid that occurs as white leaflets, colorless crystals, or as a white powder; it has a characteristic, intense odor. 2-Aminopyridine is used in the synthesis of antihistamines and other pharmaceuticals; as an intermediate in the synthesis of herbicides; and in tire manufacture (ACGIH 1986, p. 24; Merck 1983, p. 71; Hawley's 1987, p. 62; Grayson 1985, pp. 979–980). When used in pesticidal applications and in

accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

2-Aminopyridine is a systemic poison that causes headache, respiratory distress, intoxication, convulsions, and death. The LD50 in mice by intraperitoneal injection is 28 mg/kg; the LD50 in the same species by intravenous administration is 23 mg/kg (RTECS 1990). Acutely poisoned animals showed excitement, tremors, and convulsions before death (Clayton and Clayton 1981, p. 2731). Cats injected intravenously with a 1-mg/kg dose of 2-aminopyridine showed increased blood pressure and respiratory rate, with central nervous system stimulation and muscle twitching. 2-Aminopyridine is readily absorbed through the skin and may cause convulsions by this route (Clayton and Clayton 1981, p. 2732). Application of a 0.02 M solution of 2-aminopyridine to rabbit eyes from which the corneal epithelium had been removed caused slight or no injury (Grant 1986, p. 383).

A worker in a chemical plant who was acutely overexposed to aminopyridine by inhalation and skin absorption died (Spolyar 1951). In another case, a worker exposed to a 5-ppm concentration of 2-aminopyridine for 5 hours complained of headache and nausea, developed increased blood pressure, but subsequently recovered (Clayton and Clayton 1981, p. 2732).

Based on this evidence in humans and animals, OSHA proposes to establish an 8-hour TWA PEL for 2-aminopyridine of 0.5 ppm in agriculture; adoption of this proposed limit would establish the same PEL for workplaces in all OSHAregulated industry sectors. The Agency preliminarily concludes that occupational exposure to 2aminopyridine causes systemic poisoning in the form of central nervous system effects and convulsions. Accordingly, OSHA believes that, in the absence of a permissible exposure limit, workers in agriculture are potentially at significant risk for these exposurerelated effects and that the proposed PEL will substantially reduce these risks.

ANISIDINE (o-, p-isomers)
CAS: 29191-52-4; Chemical Formula:
NH₂C₆H₄OCH₃
H.S. No. 2007

OSHA's current limit for the orthoand para-isomers of anisidine in general industry, construction, and maritime workplaces is 0.5 mg/m³ as an 8-hour time-weighted average; this limit also has a skin notation, which indicates that percutaneous absorption is a significant

route of exposure for this substance. OSHA has no PEL for anisidine in agriculture. The ACGIH's current TLV*-TWA for this substance is 0.5 mg/m3 with a skin notation. NIOSH has no REL but concurs (Ex. 8-47, Table N6A) with the limit being proposed. OSHA is proposing to establish a TWA PEL of 0.5 mg/m3, and a skin notation, for anisidine in agriculture. Promulgation of this limit will make OSHA's PEL for anisidine consistent across all regulated

Anisidine has two isomers that find use in industry: the ortho-isomer, which is a reddish-brown or yellowish oil, is used in the chemical synthesis of guaiacol and various dyes, while the para-isomer, which is a fused crystalline mass, is used to produce azo dyes (ACCIH 1986, p. 31). Both isomers have the fishy odor that is characteristic of amines (Sittig 1985, p. 80).

Acute exposure to anisidine causes methemoglobinemia in animals; chronic exposure causes cancer (Proctor, Hughes, and Fischman 1988, p. 76). The oral LD50s in rats are 2 and 1.4 g/kg. respectively, for the o- and p-isomer (RTECS 1990). The dermal LD50 in rats for para-anisidine is 3200 mg/kg (RTECS 1990). Subacutely poisoned animals showed hematological changes, anemia, and kidney damage (Proctor, Hughes, and Fischman 1988, p. 77). When fed to mice or rats for 7 weeks, o-anisidine hydrochloride caused enlargement of the spleen, reductions in weight gain, an increased incidence of bladder hyperplasia (mice) and non-neoplastic lesions of the thyroid gland and kidney (rats) (IARC 1982, pp. 74-75). Oral administration of p-anisidine to mice and rats in a subchronic study also caused weight gain reductions and darkened spleens in animals of both species (IARC 1982, p. 75). In cancer bioassays in mice and rats, the oral administration of o-anisidine hydrochloride, but not p-anisidine hydrochloride, caused statistically significant increases in the incidence of transitional-cell carcinomas of the urinary bladder (IARC 1982, p. 76). Based on this evidence, the International Agency for Research on Cancer (IARC) has concluded that the evidence for the carcinogenicity of ortho-anisidine in animals is sufficient (IARC 1982, p. 77).

Workers exposed to a 1.9-mg/m3 concentration of anisidine for 3.5 hours per day for 6 months complained of headaches and dizziness and had an increase in sulfhemoglobin. methemoglobin, and Heinz bodies in their red blood cells (ACGIH 1986, p. 31). Anisidine is also an irritant and

sensitizer of the skin in humans (HSDB 1986). Based on effects seen in animals, IARC believes that o-anisidine should be regarded "* * * as if it presented a carcinogenic risk to humans" (IARC

1982, p. 77)

The evidence described above demonstrates that anisidine is a chemical asphyxiant that produces anoxia by binding to hemoglobin and that it is also an irritant and sensitizer of the skin and a probable human carcinogen. OSHA therefore preliminarily concludes that the absence of a limit for anisidine poses a significant risk of skin effects, methemoglobinemia, and potential carcinogenicity in exposed workers in agriculture. The Agency believes that the proposed TWA PEL of 0.5 mg/m3, with a skin notation, is necessary to substantially reduce these significant risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

ARSENIC and organic compounds CAS: 7440-38-2; Chemical Formula:

Varies with compound H.S. No. 2012

OSHA's limit for arsenic and the organic compounds of arsenic in general industry, construction, and maritime is 0.5 mg/m3 (measured as arsenic) as an 8-hour TWA. There is no PEL in agriculture. The ACGIH TLV®-TWA is 0.2 mg/m3; NIOSH has no REL. OSHA is proposing an 8-hour TWA PEL of 0.5 mg/m3 for arsenic and the organic compounds of arsenic in agriculture. This action would make OSHA's limit for these substances consistent across all regulated sectors.

Arsenic is a nonmetallic element that is silver-gray and crystalline in appearance; examples of its organic compounds are arsenic diethyl, arsenic dimethyl, 1-(p-arsenosophenyl)urea, arsine-tri-1-piperidinium chloride, (3-(parsonophenyl)ureido)dithiobenzoic acid, and arsphenoxide (Sax and Lewis 1989. pp. 298-307). Arsenic is an ingredient in rodenticides, insecticides, herbicides, and other products, and the organic compounds are used in both human and animal medicine (Gosselin, Smith, and Hodge 1984, p. III-42). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Arsenic and its organic compounds are considerably less toxic than the oxides and other inorganic compounds. and most of the literature therefore deals with the inorganic compounds. The LD₅₀ in rats for arsenic is 763 mg/kg

(RTECS 1990), and the LC50 for arsenic dimethyl in the same species is 3900 mg/ m3 (Stevens, DiPasquale, and Farmer 1979). Four of five cows given a single 10-mg/kg oral dose of the monosodium salt of methanarsenic acid died (Dickinson 1972, in Am. J. Vet. Res. 33:1889-1892), and chronic feeding of 50 mg/kg of the same substance caused toxic hepatitis in rabbits (Exon, Harr, and Claeys 1974, in Nutr. Rep. Int. 9:351-357). Carcinogenicity assays that have involved the oral administration of dimethylarsenic acid in mice or the subcutaneous injection of dimethylarsenic acid in the same species have been negative (IARC 1980, Vol. 23, p. 112).

Human toxicity data for pure arsenic or the organic compounds are rare. Some of the drugs used to combat syphilis in the early part of the century contained organic arsenic compounds. and therapeutic administration of these drugs often caused optic neuritis, which sometimes progressed to loss of central vision and optic atrophy [Grant 1986. p. 118). The administration of one such drug, arsphenamine, is known to have caused encephalitis, with headache, loss of consciousness, convulsions, and paralysis of some of the cranial nerves (Grant 1986, p. 119).

In agriculture, OSHA is proposing an 8-hour TWA PEL of 0.5 mg/m3 for arsenic and its organic compounds (measured as As). The Agency preliminarily concludes that this limit is necessary to reduce the significant risk of arsenic toxicity potentially associated with exposure to these substances. OSHA considers arsenic intoxication a material impairment of health and believes that the new limit is necessary to substantially reduce this risk among workers in agriculture. In addition, promulgation of this limit will make the PEL for arsenic and its organic compounds consistent across all OSHAregulated sectors.

ARSINE

CAS: 7784-42-1; Chemical Formula:

H.S. No. 2010

OSHA's permissible exposure limit for arsine in general industry, construction, and maritime workplaces is 0.05 ppm as an 8-hour TWA. The Agency has no limit for this substance in agriculture. The ACGIH TLV*-TWA for arsine is also 0.05 ppm. NIOSH has a REL for arsine of 2µg/m3 as a 15-minute ceiling. OSHA is proposing a TWA PEL for arsine of 0.05 ppm in agricultural workplaces. This action will make OSHA's PEL for arsine consistent across all regulated sectors.

Arsine is a colorless gas that has a garlic-like odor (ACGIH 1986, p. 39). Arsine is evolved when nascent hydrogen is liberated in a solution that contains inorganic arsenic; for example, arsine is liberated when arseniccontaining metals are pickled or treated with reducing acids (Clayton and Clayton 1981, p. 1518). Another source of potential exposures to arsine occurs in sulfuric acid production; if arsenic is not completely removed from the feed gases, arsine is liberated when iron comes into contact with the arsenic-containing acids (Clayton and Clayton 1981, p. 495). Arsine could also be liberated if a metal dropped into a container of arsenical pesticide or if such a pesticide were mixed in a metal vat. Arsine finds industrial use in the laboratory analysis of arsenic and as a doping agent in the semiconductor industry (Proctor, Hughes, and Fischman 1988, p. 83; Clayton and Clayton 1981, p. 1519).

Arsine is a highly toxic gas that causes nearly instantaneous death, acute renal failure, and severe intramuscular hemolysis. When inhaled, arsine is oxidized to form elemental trivalent arsenic and arsenous oxide, both recognized human carcinogens (Proctor, Hughes, and Fischman 1988, p. 831). The extent of the red blood cell breakdown caused by the inhalation of this gas is sufficient to cause the sclera of the eye and the skin to turn an intense orange color (jaundice) (Grant 1986, p. 119; Proctor, Hughes, and Fischman 1988, p. 83). Short-term inhalation of a 250-ppm concentration of this gas may cause death within 30 minutes, and inhalation even of a 10- or 50-ppm concentration for a longer period can be fatal (Proctor, Hughes, and Fischman 1988, p. 83). Symptom onset may be delayed for 2 to 24 hours; the signs and symptoms of arsine poisoning include headache, abdominal pain, weakness, dizziness, vomiting, and dark red or brown urine (hematuria) (Proctor, Hughes, and Fischman 1988, p. 83). Workers exposed for 8 months to arsine at concentrations described as "very small" had substantially reduced hemoglobin levels. Some workers had levels as low as 3.2 g/100 ml blood); these workers were involved in gold extraction operations involving cvanide leaching (Proctor, Hughes, and Fischman 1988, p. 83).

Animals exposed to arsine concentrations between 0.5 and 2 ppm for 3 hours/day for several weeks developed blood changes (ACGIH 1986, p. 39). Arsine has been responsible for several hundred fatal poisonings in humans (ACGIH 1986, p. 39).

Based on this evidence, OSHA preliminarily concludes that workers in agriculture are at significant risk of experiencing hemolysis as a result of exposure to arsine at the levels permitted by the absence of a limit for this substance. Accordingly, OSHA is proposing to substantially reduce this risk by establishing an 8-hour TWA PEL for arsine of 0.05 ppm. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. BARIUM, SOLUBLE COMPOUNDS (as

CAS: 7440–39–3; Chemical Formula: Ba H.S. No. 2015

In general industry, construction, and maritime, OSHA's permissible exposure limit for soluble barium compounds (measured as barium) is 0.5 mg/m3 as an 8-hour TWA. There is no limit in agriculture. The ACGIH has an 8-hour TLV®-TWA of 0.5 mg/m3 for barium's soluble compounds. NIOSH has no REL for these substances but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing to establish an 8-hour TWA PEL of 0.5 mg/ m3 for the soluble barium compounds in agriculture. Promulgation of this limit will make the PEL for these compounds consistent across all OSHA-regulated

Commonly used soluble barium compounds include barium nitrate. barium oxide, barium carbonate, and barium chloride, all of which are odorless, white solids. These compounds are used as rodenticides. pesticides, disinfectants, and additives; in the manufacture of photographic papers, dyes, chemicals, explosives, matches, and pyrotechnics; in water treatment; as catalysts; and in fireproofing (NIOSH/OSHA Occupational Health Guideline 1981, pp. 1, 4; Hawley's 1987, pp. 118, 120). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Exposure to the soluble barium compounds causes eye, skin, and mucous membrane irritation, central nervous system and gastrointestinal effects, and respiratory disease in humans and animals. Barium compounds can also cause reproductive effects in animals. Barium carbonate has oral LD50 values of 418 mg/kg and 200 mg/kg in rats and mice, respectively (RTECS 1990). The oral LD50 for barium chloride in rats is 118 mg/kg (RTECS 1990). In contact with the skin of rabbits, 500 mg of barium nitrate caused mild irritation; 100 mg of this substance

instilled into the eyes of rabbits caused moderate irritation (RTECS 1990). For barium oxide, the subcutaneous LD50 in mice is 50 mg/kg (RTECS 1990). Subcutaneous injection of 5 mg/kg of barium chloride caused acute toxicity and death in rabbits after 2 to 2.5 hours (Fasekas et al. 1953, in Clayton and Clayton 1981, p. 1534). The signs and symptoms of barium salt toxicity in experimental animals include salivation. vomiting, colic, diarrhea, convulsive tremors, slow, hard pulse, and elevated blood pressure. Hemorrhages in the stomach, intestines, and kidneys, followed by muscle paralysis and death, may occur a few hours or days after the exposure (Clayton and Clayton 1981, p. 1534). A recent study in guinea pigs (Hicks, Caldas, Dare, and Hewitt 1986, in Arch. Toxicol. Suppl. 9:416-420) showed that exposure to welding fumes generated in metal arc welding using barium as a flux component caused cardiotoxic and bronchoconstrictive effects. Rats given 1, 10, or 100 ppm barium in their drinking water for 1 to 16 months showed increased systolic blood pressure after exposure for 1 month at the 100-ppm level or 8 months at the 10ppm level; in the high-dose group, depressed cardiac contraction and electrical hyperexcitability were also seen (Perry, Koop, Perry, and Erlanger 1989, J. Toxicol. Environ. Health 28(3):375-388). Male rats inhaling 1150 mg/m³ of barium carbonate for 24 hours showed evidence of reproductive effects (RTECS 1990). Inhalation of barium carbonate at a concentration of 3130 µg/ m3 for 24 hours during the 16th week of pregnancy caused effects on the ovaries and fallopian tubes in female rats (RTECS 1990).

In humans, an oral dose of 800 mg/kg barium carbonate was lethal: convulsions and cardiac effects occurred before death (RTECS 1990). Barium hydroxide and barium oxide are strongly alkaline in aqueous solutions and cause severe eye burns and skin irritation on contact (Grant 1986, p. 134). Symptoms of barium intoxication in humans include nausea, vomiting, colic, and diarrhea; myocardial and general muscular stimulation and tingling of the extremities soon follow (Reeves 1979, in Proctor, Hughes, and Fischman 1988, p. 89). Inhalation of the dust of soluble barium compounds can cause a benign pneumoconiosis called baritosis; radiologic examination shows circumscribed nodules that are evenly distributed throughout both lung fields (Proctor, Hughes, and Fischman 1988, p. 1535). In a factory where bomb casings were heated in barium carbonate, bronchial irritation was reported among the workers (Elkins 1950, in Clayton and Clayton 1981, p. 1535). In a report of an accidental case of barium carbonate ingestion, symptoms of gastroenteritis, slow pulse rate, and paralysis were seen (Morton 1945, in Clayton and Clayton 1981, p. 1535). Other reports of exposure to barium compounds describe pulmonary nodulation with or without a decrease in lung function (Wende 1956; Gombos 1957, in ACGIH 1986, p. 47).

Based on this evidence, OSHA preliminarily concludes that exposure to the soluble compounds of barium causes eye, skin, and mucous membrane irritation and respiratory, gastrointestinal, and central nervous system effects. OSHA therefore believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that the proposed limit of 0.5 mg/m3 as an 8-hour TWA is necessary to significantly reduce the risk of these material health impairments. In addition, promulgation of the proposed PEL will make OSHA's limit for the soluble compounds of barium consistent across all OSHAregulated sectors.

2-BUTOXYETHANOL CAS: 111-76-2; Chemical Formula: C₄H₀OCH₂CH₂OH H.S. No. 1046

OSHA's current permissible exposure limit in construction and maritime for 2-butoxyethanol, one of the family of substances known as the glycol ethers, is 50 ppm as an 8-hour TWA, with a skin notation. There is no limit in agriculture. The ACGIH has a TLV*—TWA of 25 ppm, also with a skin notation. NIOSH has no REL but concurs (Ex. 8–47, Table N1) with the limit being proposed. OSHA is proposing a TWA—PEL of 25 ppm, with a skin notation, for this substance in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry.

2-Butoxyethanol is a colorless liquid with a mild ethereal odor. It is used as a solvent for resins, spray lacquers, varnishes, enamels, and textiles. It is also used in the dry cleaning industry (ACGIH 1986, p. 71; Hawley's 1987, p. 488).

2-Butoxyethanol has long been known to be toxic, with early studies indicating that a single 7-hour exposure to 700 ppm was lethal to laboratory animals (Werner, Mitchell, Miller, and von Oettingen 1943a, as cited in ACGIH 1986/Ex. 1–3, p. 71). Exposures near the lethal level caused systemic toxicity in the form of hemoglobinuria and lung, kidney, and liver changes. Carpenter, Pozzani, Weil, and associates (1956/Ex.

1–303) reported hemolytic anemia and increased fragility of the red blood cells in rats repeatedly exposed to 2-butoxyethanol at 320 ppm for 5 weeks. However, repeated exposure for 12 weeks at 400 ppm was only slightly injurious to dogs (Werner, Mitchell, Miller, and von Oettingen 1943b, as cited in ACGIH 1986/Ex. 1–3, p. 71).

Humans appear to be less susceptible to butoxyethanol poisoning than experimental animals. In humans, several single 8-hour exposures at levels of 200 ppm and 100 ppm caused urinary excretion of butoxyacetic acid; these subjects experienced irritation and discomfort after these exposures (Carpenter, Pozzani, Weil et al. 1956/Ex. 1-303). A recent study has confirmed that the increased erythrocyte osmotic fragility observed in rats exposed to many of the glycol ethers is a very sensitive indicator of toxicity and correlates with the development of hemoglobinuria at higher exposure levels (Moffett, Linnett, and Blair 1976, as cited in ACGIH 1986/Ex. 1-3, p. 71). These findings indicate that the noeffect level in animals is approximately 25 ppm. The ACGIH suggests that 2butoxyethanol's toxicity may be more likely to occur as a result of skin absorption than as a consequence of inhalation (ACGIH 1986/Ex. 1-3, p. 71).

OSHA preliminary concludes that the current PEL of 50 ppm in construction and maritime is insufficiently protective against the risk of 2-butoxyethanol's irritant, hematological, and other potential systemic effects, which OSHA considers material health impairments. Accordingly, OSHA is proposing to lower the PEL in these two sectors to 25 ppm, to retain the skin notation, and to extend the PEL and the skin notation to agriculture. The proposed limit will reduce the significant risk associated with exposure to 2-butoxyethanol to a level below that at which these toxic effects have been observed in animals and humans. This lower limit will also prevent the discomfort experienced by workers at exposure levels of 40 ppm. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. tert-BUTYL CHROMATE (as CrOs) CAS: 1189-85-1; Chemical Formula:

[(CH₃)₃CO]₂CrO₂ H.S. No. 2024

In general industry, construction, and maritime, OSHA's current permissible exposure limit for tert-butyl chromate (measured as CrO₃) is 0.1 mg/m³ as a ceiling limit; this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance.

There is no limit for tert-butyl chromate in agriculture. The ACGIH has a TLV*-TWA of 0.1 mg/m³ as a ceiling limit, with a skin notation, for tert-butyl chromate. NIOSH has a REL of 1 μ g/m³ (measured as hexavalent chromium) as a 10-hour TWA for this substance. OSHA is proposing to establish a PEL of 0.1 mg/m³ as a ceiling, with a skin notation, for tert-butyl chromate in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

tert-Butyl chromate is a liquid that is used as an organic source of chromium in specialty reactions, in the oxidation of steroids, and in the manufacture of catalysts for the polymerization of olefins (Sittig 1985, pp. 162–163; NIOSH/OSHA 1981). tert-Butyl chromate is a hexavalent chromium compound.

tert-Butyl chromate causes marked eye, skin, and respiratory tract irritation and central nervous system effects in animals. Because tert-butyl chromate is a hexavalent chromium compound, it is likely to cause lung and sinus cancer in humans (Sittig 1985, p. 163). There are no acute toxicity data specific to tert-butyl chromate. Rats exposed repeatedly for 30 to 60 minutes to daily lethal concentrations (dose unspecified) of a mixture of tert-butyl chromate and butyl alcohol showed signs of lacrimation, drowsiness, ataxia, prostration, muscular weakness, twitching, weight loss, rapid and superficial respiration, and necrosis of the skin and subcutaneous tissues (NIOSH/OSHA 1981). At autopsy, extensive epithelial exudation was seen in the liver of these animals (NIOSH/OSHA 1981). In other inhalation studies (species and doses unspecified), tert-butyl chromate caused mild narcosis and rapid respiration (NIOSH/OSHA 1981).

Based on effects seen in animals, workers exposed to tert-butyl chromate are expected to develop pulmonary changes, to experience narcosis, and to develop necrotic lesions of the skin if their skin comes into contact with this substance (Roubal and Krivucova 1960, in ACGIH 1986, p. 80). tert-Butyl chromate can also be absorbed through the skin in toxic amounts, and eye contact with this substance causes severe damage (Hazardous Substance Fact Sheet 1986, p. 1). Contact of the skin with tert-butyl chromate causes deep ulcers and may cause dermal sensitization (Hazardous Substance Fact Sheet 1986, p. 1). Inhalation of tert-butyl chromate vapors may cause ulceration of the nasal septum, with bleeding, discharge, and crusting (Hazardous Substance Fact Sheet 1986, p. 1) Chronic exposure to low concentrations of tertbutyl chromate also can cause liver and kidney damage (Hazardous Substance

Fact Sheet 1986, p. 1).

Based on this evidence, OSHA preliminarily concludes that tert-butyl chromate causes skin, mucous membrane, and respiratory irritation and may cause cancer in exposed workers. OSHA therefore believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that the proposed ceiling PEL of 0.1 mg/m3, with a skin notation, is necessary to significantly reduce the risk of material health impairment among agricultural workers. In addition, promulgation of this limit will make the PEL for this substance consistent across all OSHAregulated sectors.

n-BUTYL GLYCIDYL ETHER (BGE) CAS: 2426-08-6; Chemical Formula: C4H9OCH2CH2OH H.S. No. 1052

The OSHA limit for n-butyl glycidyl ether in construction and maritime is 50 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH TLV*-TWA is 25 ppm; NIOSH has recommended that occupational exposure to n-butyl glycidyl ether not exceed 5.6 ppm over a 15-minute short-term period. The Agency is proposing a PEL of 25 ppm as an 8-hour TWA for n-butyl glycidyl ether in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry.

substance in general industry.

n-Butyl glycidyl ether is a clear,
colorless liquid. It is used as a reducing
agent and acid receptor, to stabilize
chlorinated solvents, and as a chemical
intermediate (ACCIH 1986, p. 81;
Clayton and Clayton 1981, p. 2201).

OSHA's current PEL of 50 ppm in construction and maritime was adopted from the ACGIH's 1968 TLV® list. The basis for the ACGIH limit was that repeated applications of n-butyl glycidyl ether to the skin of humans caused irritation and sensitization. The NIOSH limit of 5.6 ppm is based, in large part, on mutagenic studies conducted in microbial and mammalian test systems, as well as on some evidence for other members of the glycidyl ether family showing that exposure is associated with testicular atrophy and hematopoietic abnormalities in laboratory animals. After publication of its criteria document, NIOSH received a confidential report prepared for the Shell Development Company by Anderson et al. (1957, as cited in ACGIH 1986/Ex. 1-3, p. 81), who had conducted a rat inhalation study. In this research.

rats were exposed to 38 ppm, 75 ppm, 150 ppm, or 300 ppm n-butyl glycidyl ether for 7 hours daily, 5 days per week for 10 weeks. Atrophic testes were found in 5 of 10 rats exposed to 300 ppm, very small testes were found in 1 of 10 rats exposed to 150 ppm, and patchy atrophy was found in the testes of 1 of 10 rats exposed to 75 ppm. No effects were observed in rats exposed at 38 ppm. Based on this additional evidence, NIOSH reaffirmed its REL for n-butyl glycidyl ether in a Current Intelligence Bulletin (NIOSH 1978p). n-Butyl glycidyl ether also causes mild to moderate irritation in contact with the skin of rabbits; instilled into the eyes of animals of the same species, this substance caused severe irritation (RTECS 1990). The oral LD50 in rats is 2050 mg/kg, and the dermal LDso in rabbits is 2520 mg/kg (RTECS 1990). The lowest lethal concentration in rats is 670 ppm (RTECS 1990). Animals given intragastric or intraperitoneal injections of n-butyl glycidyl ether developed incoordination and ataxia before death (Hine et al. 1956, in AMA Arch Ind Hlth 14:250-264). Intracutaneous injection of this substance in guinea pigs led to sensitization in 16 of 17 of these animals (Hine et al. 1956).

OSHA believes that this proposal has taken reasonable account of the limited data for this substance; accordingly, OSHA preliminarily concludes that reducing the PEL from 50 ppm to 25 ppm will substantially reduce the significant risk of reproductive effects and will also protect workers in construction, maritime, and agriculture from BGE's irritant and sensitization effects, all of which constitute material health impairments. The Agency therefore proposes a permissible exposure limit of 25 ppm TWA for n-butyl glycidyl ether in construction, maritime, and agriculture. Promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

CAPTAN

CAS: 133-06-2; Chemical Formula: C₈H₈Cl₈NO₂S

H.S. No. 1067

OSHA has no PEL for captan in construction, maritime, or agriculture. The ACGIH has a TLV®-TWA of 5 mg/m³ for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N6A) with the limit being proposed. The Agency is proposing a PEL of 5 mg/m³ as an 8-hour TWA for captan in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry.

Captan is a white, crystalline, odorless solid. Captan is used for seed treatment, as a fungicide in paints, in plastics, leather, fabrics, fruit preservation, and as a bacteriostat. When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Skin applications of 900 mg/kg captan produce skin irritation in experimental animals. Long-term feeding studies did not reveal adverse effects in dogs fed captan in the diet at levels of 100 mg/ kg/day for 66 weeks or in rats fed 1000 mg/kg/day for 2 years [Martin 1971/Ex. 1-1161; Spencer 1968, as cited in ACGIH 1986/Ex. 1-3, p. 98). Male mice showed decreased fertility at captan levels of 50 or 100 mg/kg/day for 5 days (Collins 1972/Ex. 1-893). Studies on the mutagenicity of captan indicate that the substance acts as an alkylating agent and induces chromosome rearrangements in rats and point mutations in Neurospora crassa (Epstein and Legator, as cited in ACGIH 1986/Ex. 1-3, p. 98). Legator and colleagues (1969, as cited in ACGIH 1986/Ex. 1-3, p. 98) reported that captan concentrations of 10 ug/ml inhibited DNA in human embryo cells, and concentrations of 1.5 ug/ml produced chromosomal aberrations in the somatic and germ cells of kangaroo rats. Animal evidence concerning the carcinogenicity of captan is contradictory, although high doses caused significant incidences of polyploid carcinoma of the duodenum and adenomatous polyps in mice (NCI 1977a, as cited in ACGIH 1986/Ex. 1-3.

Some captan-exposed individuals experience skin irritation (Spencer 1968, as cited in ACGIH 1986/Ex. 1-3, p. 98). A case of recurrent urticaria caused by captan exposure has been reported and confirmed (Croy 1973/Ex. 1-894), and captan caused high reactivity when administered in a battery of patch tests

(Rudner 1977/Ex. 1-967).

OSHA is proposing a PEL of 5 mg/m3 as a TWA to protect workers exposed to captan in the construction, maritime, and agriculture industries from the significant risk of exposure-related skin irritation, reproductive effects, mutagenicity, and, perhaps, carcinogenicity, all of which constitute material health impairments. The Agency preliminarily concludes that this limit will substantially reduce these significant risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. CARBARYL (SEVIN®)

CARBARYL (SEVIN*)
CAS: 63-25-2; Chemical Formula
C₁₂H₁₁NO₂

H.S. No. 2026

OSHA's current limit for carbaryl in general industry, construction, and maritime workplaces is 5 mg/m3 as an 8-hour TWA. OSHA has no PEL for carbaryl in agriculture. The 1987-1988 ACGIH TLV*-TWA for carbaryl is 5 mg/m³; the NIOSH recommended exposure limit (REL) for this substance is 5 mg/m3 as a 10-hour time-weighted average. OSHA is proposing to establish a PEL of 5 mg/m3 as an 8-hour TWA for carbaryl in agriculture. This is the limit recently established for carbaryl in general industry.

Carbaryl is an odorless solid that is crystalline and white or grayish in color (Proctor, Hughes, and Fischman 1988, p. 115; ACGIH 1986, p. 99). Carbaryl is widely used in agriculture as an insecticide for corn, vegetables, sovbeans, cotton, deciduous fruits, nuts, alfalfa, wheat, and many other crops. It is also used as an insecticide for gardens, turf, ornamentals, forests, livestock, and poultry. In addition, carbaryl is an effective acaricide and molluscicide (HSDB 1985). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Carbaryl is a carbamate pesticide; like other carbamates, this substance causes reversible cholinesterase inhibition in humans and animals. In animals, carbaryl also causes irritation of the eyes and skin when in contact with these organs (RTECS 1920). There is some evidence in experimental animals that carbaryl causes reproductive effects in female animals and developmental effects in the offspring of exposed animals (RTECS 1990; EPA 1987). The oral LDso in rats is 250 mg/kg, and the dermal LD₅₀ in rabbits is 2000 mg/kg (RTECS 1990). Dogs exposed by inhalation to a carbaryl dust concentration of approximately 75 mg/ m3 showed evidence of cholinesterase inhibition, but rats exposed to the dust at a concentration of 10 mg/m3 for 7 hours/day for 90 days showed no such effects (ACGIH 1986, p. 99).

Dogs fed single oral doses of carbaryl ranging from 250 to 500 mg/kg showed signs of overstimulation of the parasympathetic nervous system (increased respiratory rate, salivation. muscular twitching, incoordination), at the two highest doses; however, red blood cell cholinesterase activity declined by 24 to 33 percent in the 375mg/kg dose group (EPA 1987). Decreases in red blood cell cholinesterase activity have also been seen after the administration of single oral doses of

carbaryl to rats (Carpenter et al. 1961; Weil et al. 1968).

Reproductive effects (reduced fertility. increase in number of resorptions, decrease in number of live fetuses/litter) have been seen in female rats, rabbits, mice, and gerbils (Weil et al. 1972; Murray et al. 1979; Collins et al. 1970). and some studies have shown developmental effects (omphalocele, conjoined nostrils, delayed ossification) among the offspring of pregnant rabbits and mice given carbaryl during gestation

(Murray et al. 1979).

In humans, exposure to carbaryl causes a depression in cholinesterase activity that is reversible on cessation of exposure. After a large-scale carbaryl spraying operation in Nigeria, eight applicators had 15-percent reductions in their plasma cholinesterase activity levels (Vanderkar 1965). Male volunteers who ingested doses of carbaryl of up to 0.13 mg/kg/day for 6 weeks showed no signs and reported no symptoms of cholinesterase poisoning (Gosselin, Smith, and Hodge 1984, p. III-87). A human suffered from moderate poisoning after ingesting 250 mg of carbaryl; after a short period (20 minutes) with no symptoms, abdominal pain, profuse sweating, lassitude, and vomiting developed in this individual (Proctor, Hughes, and Fischman 1988, p. 115). Workers exposed for 19 months to carbaryl at concentrations ranging from 0.23 to 0.31 mg/m3 showed no signs or symptoms of cholinesterase inhibition (Proctor, Hughes, and Fischman 1988, p. 115).

The evidence described above shows that carbaryl exposure causes irritation and inhibition of cholinesterase activity in both humans and animals, and that it has reproductive and teratogenic effects in animals. Accordingly, OSHA preliminarily concludes that, in the absence of a limit, workers in agriculture are potentially at significant risk of experiencing these exposurerelated effects. The Agency believes that the proposed 8-hour TWA limit of 5 mg/ m3 for carbaryl will substantially reduce these risks for workers in this sector. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. beta-CHLOROPRENE

CAS: 126-99-8; Chemical Formula:

CH2:CClCH:CH2 H.S. No. 1088

The current OSHA limit for betachloroprene in construction and maritime is an 8-hour TWA of 25 ppm, with a skin notation. There is no limit in agriculture. The ACGIH has a 10-ppm TLV*-TWA, with a skin notation, and NIOSH (1977c/Ex. 1-277) recommended

a ceiling limit of 1 ppm, measured over a 15-minute period. In construction, maritime, and agriculture, the Agency is proposing an 8-hour TWA PEL of 10 ppm; the skin notation is retained in construction and maritime and proposed in agriculture. NIOSH (Ex. 8-47, Table N1) concurs with this limit, which was recently established for this substance in general industry.

beta-Chloroprene is a colorless, highly flammable liquid. It is used in the production of neoprene (ACGIH 1986, p.

135; Hawley's 1987, p. 271)

The ACGIH recommended a reduction in the TLV* for beta-chloroprene from 25 ppm to 10 ppm in 1981, based on a review of the world literature by Trochimowicz, who prepared the 1980 ACGIH documentation, and by Reinhardt (1980, as cited in ACGIH 1986/Ex. 1-3, p. 135). Reinhardt concluded that there was no evidence indicating that the former 25-ppm PEL was not protective, but OSHA believes the systemic effects (in the form of growth retardation) seen in rats and hamsters exposed to 39 ppm betachloroprene for 4 weeks or to 50 ppm for a lifetime suggest that the 25-ppm PEL is

not sufficiently protective.

When NIOSH established a REL of 1 ppm for beta-chloroprene, NIOSH (1977c/Ex. 1-277) cited three reports on beta-chloroprene-using facilities in the Soviet Union. Katsova (1973, as cited in ACGIH 1986/Ex. 1-3, p. 135) reported finding a significant excess of chromosomal abnormalities in the blood of workers exposed to approximately 5 ppm beta-chloroprene. Volkova, Fomenko, Bagdinov et al. (1976/Ex. 1-1025) reported similar findings in a plant where beta-chloroprene levels ranged from 0.8 to 1.95 ppm. In the third study, Sanotskii (1976/Ex. 1-662) reported abnormal sperm morphology among workers exposed at levels of from 0.28 to 1.94 ppm; a threefold increase in the rate of spontaneous abortion among wives of these workers was also found. In addition, NIOSH (1977c/Ex. 1-277) cited a study by Davtiani, Fomenko, and Andreyeva (1973/Ex. 1-1032) that reported a significant excess of embryonic mortality in female rats that were mated to male rats exposed to 1 ppm beta-chloroprene. These investigators also found chromosomal aberrations in the bone marrow cells of exposed male rats. NIOSH (19Wc/Ex. 1-277) also cited a number of reports showing beta-chloroprene to be mutagenic in a variety of test systems. NIOSH concluded that it was prugent to reduce exposure to 1 ppm over a 15minute period, to reduce the risk of genetic abnormalities being transmitted

to subsequent generations. This exposure represents the lowest concentration that can be measured reliably over a 15-minute period.

However, OSHA notes that sizeable discrepancies exist between the findings from the Russian studies and results from other studies that were undertaken to confirm the Soviet claims. Torkelson and Rowe (1981c, in "Patty's Industrial Hygiene and Toxicology," 3rd rev. ed., Vol. 2B, Clayton and Clayton 1981) offer two possible explanations for these discrepancies:

beta-Chloroprene is a very unstable compound, which, unless handled with extreme care, * * * [epoxidizes] and polymerizes to toxic compounds. This might explain the alleged effects in animals. Alleged effects in humans may be due to this same cause or to the use of different chemical processes which produce different types of impurities. Many other causes can be postulated, but in our opinion more credence must be given to animal studies in which the sample is known to have been handled with extreme care and to the results of experience in U.S. industry where the method of handling has been reported (Torkelson and Rowe 1981c, p. 3578).

These authors report that when the purity of the sample was carefully controlled, repeated exposures to 25 ppm or less of the vapor have caused no reproductive, teratological, or embryotoxic effects in rats: "Despite frank clinical toxicity in exposed pregnant rats, fetuses showed no teratogenic effects at beta-chloroprene levels as high as 175 ppm" (Torkelson and Rowe 1981c, pp. 3579–80).

The 1-ppm (15-minute STEL) value recommended for this substance by NIOSH is based on studies reported in the Soviet literature: in addition, the REL is set at the analytical limit of detection. OSHA's 10-ppm PEL is based on a 1981 critical review of the world literature (Trochimowicz 1980, as cited in ACGIH 1986/Ex. 1-3, p. 135) and on the observation that only mild systemic effects are observed after exposure to this substance at 38 ppm. OSHA is proposing an 8-hour TWA PEL of 10 ppm, with a skin notation, for betachloroprene in the construction, maritime, and agricultural sectors, to substantially reduce the significant risk of reproductive and systemic effects, which constitute material health impairments that are potentially associated with exposure to betachloroprene. The Agency preliminarily concludes that the proposed limit will substantially reduce this significant risk. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

CYANIDES (as CN)

CAS: Varies with compound; Chemical Formula: Varies with compound H.S. No. 2045

In general industry, construction, and maritime, OSHA's permissible exposure limit for cyanides is 5 mg/m3 as an 8hour TWA; this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for cyanides. There is no limit in agriculture. The ACGIH has a TLV®-TWA of 5 mg/m³, with a skin notation. NIOSH has a REL of 5 mg/m³ as a 10-minute ceiling for the cyanide salts. OSHA proposes to establish a TWA PEL of 5 mg/m3, with a skin notation, for the cyanides in agriculture. Promulgation of this limit will make the PEL for the cyanides consistent across all OSHA-regulated sectors.

The principal cyanides in industrial use are potassium and sodium cyanide and calcium cyanide (Proctor, Hughes, and Fischman 1988, p. 166). Potassium cyanide and sodium cyanide are white deliquescent solids that have a faint. bitter, almond-like odor. Cyanides find use as insecticides and fumigants, in the extraction of gold and silver ores, in electroplating and metal cleaning, in the manufacture of dyes, pigments, nylon, and chelating agents, in the heat treatment of metals, in photography, and as reagents in analytical chemistry (ACGIH 1986, p. 153; Hawley's 1987, pp. 954, 1057). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide,

Fungicide, and Rodenticide Act (FIFRA). Cyanides cause systemic effects and eye, skin, and respiratory tract irritation in humans and animals. Sodium cyanide has an oral LD₅₀ of 6440 μg/kg in rats (RTECS 1990). The oral LD508 for potassium cyanide in rats, mice, and rabbits are 10 mg/kg, 8.5 mg/kg, and 5 mg/kg, respectively (RTECS 1990). The ocular LD50 in rabbits for sodium cyanide is 5 mg/kg; in rabbits, the ocular LDso for potassium cyanide is 7.8 mg/kg (RTECS 1990). Various species (monkeys, cats, dogs, and rats) given daily subcutaneous injections of potassium cyanide at lethal levels showed signs of nystagmus, periods of blindness, and degeneration of the optic nerve, chiasm, and optic tract (Grant 1986, p. 287). A recent study in mice showed that subcutaneous injection of 10 mg/kg potassium cyanide increased the levels of blood ammonia to 2.5 times those of controls: all animals subsequently lapsed into unconsciousness (Yamamoto 1989, in Toxicol. Appl. Pharmacol. 99(3):415-420). The author suggests that

hyperammonemia and increased neutral and aromatic amino acids may be important in the loss of consciousness associated with cyanide exposure. An oral dose of 65 g/kg potassium cyanide caused effects on the reproduction and fertility of female rats when administered 14 days before and on days 1 through 22 of pregnancy (RTECS 1990 "Potassium Cyanide").

In humans, the cvanide ion has essentially the same toxicity whatever the route of absorption (Hayes 1982, p. 127). The estimated LC50 in humans is 3404 ppm for a 1-minute exposure (NIOSH Criteria Document 1976). After 6 to 8 minutes, exposure to 270 ppm is fatal; 181 ppm is lethal after 10 minutes. and 135 ppm is fatal after a 30-minute exposure (NIOSH Criteria Document 1976). The signs and symptoms of less severe exposure to any of the cyanides include weakness, headache, confusion, nausea, and vomiting (NIOSH Criteria Document 1976). In humid atmospheres, cyanide solutions cause skin and respiratory tract irritation and may cause an allergic contact dermatitis (NIOSH Criteria Document 1976). Cyanide salt solutions cause itching and discoloration or corrosion of the skin due to the alkalinity of these solutions: exposure to solutions as dilute as 0.5 percent potassium cyanide has caused skin irritation and symptoms such as headaches and dizziness (NIOSH Criteria Document 1976). In one case, an individual who ingested 600 mg of potassium cyanide experienced acute pulmonary edema and lactic acidosis (Graham, Laman, Theodore, and Robin 1977, in Proctor, Hughes, and Fischman 1988, p.167). The signs and symptoms of chronic exposure to cyanides include weakness, nausea, headache, and vertigo (NIOSH Criteria Document 1976). Thirty-six silver-reclaiming facility workers repeatedly exposed to cyanide (concentrations not specified) continued to experience symptoms as long as 7 months or more after exposure ended; at least 30 percent of these workers reported experiencing headache, eye irritation, easy fatigue, loss of appetite, and nose bleeds (Blanc et al. 1985, in Proctor, Hughes, and Fischman 1988, p.167). A 39-year old worker suffered from loss of appetite, nervousness, dizziness, headache, nausea, vomiting, and weight loss caused by repeated exposure to cyanide when he put very hot iron into a hardening bath (Wuthrich 1954, in Hayes 1982, p.127). The illness disappeared during the patient's 2- or 3week absence from work; however, his symptoms returned within 1 month after

1982, p. 127).

Based on this evidence in humans and animals, OSHA preliminarily concludes that exposure to any of the cyanides causes eye, skin, and respiratory tract irritation and systemic effects in humans and animals. OSHA therefore believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that the proposed limit of 5 mg/m3 as an 8-hour TWA, and a skin notation, is necessary to significantly reduce these risks of material health impairment among these workers. Promulgation of this limit will also make the PEL for these substances consistent across all OSHA-regulated sectors.

CYCLOHEXYLAMINE CAS: 108-91-8; Chemical Formula: CsH13N H.S. No. 1109

OSHA has no limit for cyclohexylamine in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 10 ppm. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the proposed limit. OSHA is proposing a PEL of 10 ppm as an 8-hour TWA for cyclohexylamine in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry

Cyclohexylamine is a liquid with a strong, fishy, amine odor. It is used in the manufacture of insecticides, plasticizers, and dry cleaning soaps, as a corrosion inhibitor, and as a chemical intermediate (ACGIH 1986, p. 161; Merck 1983, p. 392). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Data concerning the acute toxicity of cyclohexylamine were reported by Eastman Kodak in 1958 (ACGIH 1988/ Ex. 1-3, p. 161). In rats, the oral LD50 of a 5-percent solution in water was between 400 and 800 mg/kg; mice fed a diet of the 1-percent aqueous solution or the undiluted amine had LDsos of between 200 and 400 mg/kg. Injection of the 5percent aqueous solution in rats produced LD₅₀s of between 5 and 25 mg/ kg, while mice injected intraperitoneally with the 1-percent solution had LDros of between 5 and 10 mg/kg. In guinea pigs, the dermal LD50 of undiluted cyclohexylamine is reported to be between 1 and 5 ml/kg. Edema, necrosis, and eschars were reported as a consequence of these dermal exposures. In rabbits, one drop of a 50-percent solution caused complete destruction of the eye. Six-hour inhalation exposures

return to work (Wuthrich 1954, in Hayes -at a vapor concentration of 12,000 ppm caused deaths in rats, but exposure to 1000 ppm caused neither toxic effects nor deaths.

> Legator, Palmer, Green, and Petersen (1969/Ex. 1-496) considered cyclohexylamine to be a potential carcinogen, mutagen, or teratogen on the basis of dose-dependent chromosomal abnormalities observed in rats injected intraperitoneally with cyclohexylamine. Khera, Stolz, Gunner et al. (1971/Ex. 1-343) noted adverse effects on rat fertility, and Becker and Gibson (1970/ Ex. 1-298) reported embryotoxic effects in mice intraperitoneally injected with cyclohexylamine. In contrast, Kennedy, Sanders, Weinberg et al. (1969, as cited in ACGIH 1986/Ex. 1-3, p. 161) reported no effects of exposure to cyclohexylamine on rabbit and rat fertility, reproduction, embryogenesis, or perinatal and postnatal development.

> In general, there is agreement concerning the moderate to severe toxicity of cyclohexylamine and its potential for intense skin irritation and moderate skin sensitization (Sax 1968b, as cited in ACGIH 1986/Ex. 1-3, p. 161). The chemical is well known to be pharmacologically active, having sympathomimetic activity (Barger and Dale 1910/Ex. 1-1104). However, Litchfield and Swan (1971/Ex. 1-346) report that human dietary levels of 5 g/ day for 7 to 8 days produced no pharmacologically active levels in the tissues; furthermore, no changes were detected in blood pressure, heart rate, or electrocardiograms of exposed subjects. Chronic experimental toxicity data are lacking, but Watrous and Schulz (1950/ Ex. 1-940) have reported that exposure to 4 to 10 ppm of cyclohexylamine caused no symptoms of any kind in acutely exposed employees.

OSHA is proposing an 8-hour TWA PEL of 10 ppm for cyclohexylamine in construction, maritime, and agriculture. The Agency preliminarily concludes that limiting workplace exposures to this substance to the 10-ppm level will protect workers in these sectors from the significant risks of severe skin and eye irritation and sensitization, all material health impairments that are associated with exposure to cyclohexylamine. OSHA believes that this limit is necessary to substantially reduce these significant occupational risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

CYHEXATIN CAS: 13121-70-5; Chemical Formula:

(C₆H₁₁)₃SnOH H.S. No. 1112

OSHA has no limit for cyhexatin in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 5 mg/ m3 for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the proposed limit. The Agency is proposing a 5 mg/m3 TWA-PEL for cyhexatin in construction, maritime, and agriculture. This is the limit recently established for cyhexatin in general

At room temperature, cyhexatin exists in the form of white crystals. Cyhexatin is used as a biocide and it is also an effective miticide (ACGIH 1986, p. 165). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and

Rodenticide Act (FIFRA).

Cyhexatin has oral LD50s of 500, 700, and 190 mg/kg for rabbits, guinea pigs, and rats, respectively (NIOSH 1977i/Ex. 1-1182). Skin exposure to a 1- to 2percent solution of cyhexatin in goats and cattle caused mild effects; sheep showed mild effects after application of a 0.5-percent solution. One of five sheep died from multiple skin applications of a 1-percent suspension (Johnson, Younger, Witzel, and Radeleff 1975/Ex. 1-336).

The toxicity of cyhexatin is considered to be moderate, although it is greater than the toxicity of most other organic tin compounds. Long-term feeding in rats produced no behavioral changes, mortality, tissue changes, or hematologic or biochemical alterations in response to 2 years of dosing at 12 mg/kg per day; however, dosed animals were smaller than controls. After daily doses by gavage of 24 mg/kg per day for 2 weeks, rats showed microscopic changes in the liver, kidneys, and adrenal glands at autopsy. Six mg/kg is considered to be the no-effect level in rats, and in dogs, the no-effect feeding level is reported to be 3 mg/kg. Rats fed 4 to 6 mg/kg, and rabbits fed 3 mg/kg, showed no ill effects on indices for fertility, gestation, viability, or lactation (Dow Chemical Company 1973d, as cited in ACGIH 1986/Ex. 1-3, p. 165). No inhalation data on animals are available, and there are no human data.

OSHA is proposing an 8-hour TWA limit of 5 mg/m3 for cyhexatin in construction, maritime, and agriculture. OSHA preliminarily concludes that a PEL of 5 mg/m3 will protect workers in these sectors against the significant risk of skin and respiratory irritation, as well as other possible adverse effects associated with exposure in the absence of a limit. The Agency considers these adverse health effects to be material health impairments within the meaning of the Act. Promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

DICHLOROPHENOXYACETIC ACID) CAS: 94-75-7; Chemical Formula: C₈H₆C1₂O₃

H.S. No. 2050

In general industry, construction, and maritime, OSHA's permissible exposure limit for 2,4-D is 10 mg/m3 as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 10 mg/ m3 for 2.4-D. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing to establish an 8-hour TWA PEL of 10 mg/m3 for 2,4-D in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

2.4-D. also called 2.4. dichlorophenoxyacetic acid, is a white to yellow powder with a light phenol-like odor. It is a selective herbicide used to control broadleaf weeds (Hayes 1982, p. 521; ACGIH 1986, p. 167). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

2,4-D causes skin irritation, central nervous system effects, and liver and kidney damage in humans and animals; it also causes reproductive and teratogenic effects in animals. The oral LD₅os for rats, mice, guinea pigs, and hamsters are 370 mg/kg, 368 mg/kg, 469 mg/kg, and 500 mg/kg, respectively (RTECS 1990). The dermal LDso in rats is 1500 mg/kg; in rabbits it is 1400 mg/kg (RTECS 1990). Monkeys showed no serious ill effects from a 2,4-D dose of 214 mg/kg (Hill and Carlisle 1947, in Hayes 1982, p. 521). Acute toxicity causes virtually the same effects in all species; death usually occurs as a result of ventricular fibrillation (ACGIH 1986, p. 167). Acutely poisoned animals show stiffness, incoordination, lethargy stupor, and coma before death (ACGIH 1986, p. 167). Dogs administered a 100mg/kg dose of 2,4-D developed irritation of the gastrointestinal mucosa, hepatic necrosis, and mild renal tubular degeneration (Drill and Hirtzaka 1953, in EPA Health Advisory 1987, p. 4). Repeated doses of 2,4-D can lead to loss of appetite, weight loss, vomiting, depression, roughness of coat, tenseness, and muscular weakness (Hayes 1982, p. 521). Female rats given 300 mg/kg of 2,4-D orally five times a week for 4 weeks showed depressed growth rates, liver pathology, and gastrointestinal irritation (National Research Council 1977, in HSDB 1985). A single intraperitoneal dose of 240 mg/kg

or daily oral doses of 40 mg/kg for 30 days caused an alteration in brain mitochondrial oxidative phosphorylation manifested by an increase in body temperature, increased mitochondrial ATPase activity, and increased oxygen consumption in male rats (Podolak 1981, in Dangerous Properties of Industrial Materials Report 1987, Vol. 7, p. 17). Rats fed doses of 5, 15, or 45 mg/kg/day for 90 days had significant reductions in blood indices at all doses and reduced liver enzyme activities at higher doses; there was also evidence of kidney toxicity at the higher dose (Hazelton Laboratories 1983, in EPA Health Advisory 1987, p. 4). Male and female rats ingesting 2,4-D had increased incidences of malignant neoplasms and lymphosarcomas; female rats developed neoplasms of the mammary gland, while males had carcinomas of the endocrine organs (Reuber 1983, in HSDB 1985). At a dose of 110 mg/kg/day, 2,4-D is teratogenic and embryotoxic in mice (Baage et al. 1973, in Hayes 1982, p. 523). A sow receiving 500 mg/kg of 2,4-D in her diet throughout pregnancy had underdeveloped and apathetic piglets; 10 of 15 died within 24 hours of birth (Bjorklund and Erne 1966, in IARC 1977, Vol. 15, p. 123). Continued 2,4-D feeding of surviving piglets for 8 months caused marked growth depression, persistent anemia, and degenerative changes of the liver and kidneys (Bjorklund and Erne

1966, in IARC 1977, Vol. 15, p. 123). In humans, the lowest lethal oral 2,4-D dose is 80 mg/kg; before death, gastrointestinal effects, behavioral symptoms, and coma occurred (RTECS 1990). An oral 2,4-D dose of 93 mg/kg caused convulsions (RTECS 1990). Contact of 2,4-D with the skin can cause dermatitis (Seabury 1963; Hayes 1963, in Proctor, Hughes, and Fischman 1988, p. 192). Five female forestry workers who applied a 2,4,5-T and 2,4-D mixture with brushes experienced severe toxic contact eczema on the exposed areas of their skin (Jung and Wolf 1977, in Hayes 1982, p. 524). An intravenous dose of 3.6 g of 2,4-D for medicinal treatment caused stupor, hyporeflexia, fibrillary twitching of some muscles, and urinary incontinence; 24 hours later, the patient still showed muscular weakness, but this ended after another 24 hours (Seabury 1963; Hayes 1963, in Proctor, Hughes, and Fischman 1988, p. 192). The American Medical Association received reports of several cases of illness involving workers engaged in the field application of 2,4-D; symptoms included a burning sensation in the throat and chest, weakness, loss of appetite and weight, and slight albuminuria; these symptoms were a result of inhaling 2,4-D (Queries and Minor Notes 1956; in ACGIH 1986, p. 167). A male student ingested 6 g of a commercial herbicide preparation of the dimethylamine salt of 2,4-D and experienced vomiting and convulsions prior to death; autopsy showed degenerative ganglion cell changes in the brain (Neilson et al. 1965, in EPA Health Advisory 1987, p. 4).

Three cases of peripheral neuropathy resulting from the spraying of 2,4-D have been reported. In one case, paresthesia of the extremities, pain in the legs, and muscle twitching appeared within 4 to 5 days; however, no neurological or electromyographical changes were seen in this case (Goldstein et al. 1959, in IARC 1977, Vol. 15, p. 127). In the second case, numbness and aching occurred in the fingers and toes 1 week after a second exposure; 6 weeks later, the patient had a well-developed neuropathy (Goldstein et al. 1959, in IARC 1977, Vol. 15, p. 127). In the third case reported, a second exposure to 2,4-D caused severe leg pain and swelling of the metacarpal joints of both hands: 5 months later, flaccid paraparesis was seen (Goldstein et al. 1959, in IARC 1977, Vol. 15, p. 127). In similar cases of workers exposed to 2,4-D during spraying operations, signs and symptoms of muscular weakness, vomiting, diarrhea, fever, hyperthermia, tachycardia, and neurological effects (which continued to occur for 40 days to 2 years after exposure) were reported (Monarca and DiVito 1961; Paggiaro et al. 1974; Todd 1962, in IARC 1977, Vol. 15, p. 128). Of 292 workers involved in the manufacture of 2,4-D compounds for periods ranging from less than 5 years to 6 to 10 years, 63 percent reported experiencing symptoms of weakness, rapid fatigue, headache, and vertigo, while about 20 percent had cardiovascular effects such as hypotension and bradycardia and digestive disturbances such as dyspeptic symptoms and gastritis (Bashirov 1969, in IARC 1977, Vol. 15, p. 128). Workers with longer exposures to 2,4-D compounds showed more pronounced liver dysfunction than workers exposed for shorter periods (Bashirov 1969, in IARC 1977, Vol. 15, p. 128).

Based on this evidence in humans and animals, OSHA preliminarily concludes that 2.4-D causes skin irritation and central nervous system, liver, and kidney effects in humans and animals. OSHA therefore believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. OSHA believes that the proposed 8-hour TWA PEL of 10 mg/m3 for 2,4-D in agriculture is necessary to

significantly reduce the risks of these material health impairments. In addition, promulgation of the proposed PEL will make OSHA's limit for 2,4-D consistent across all OSHA-regulated sectors.

DICHLORODIPHENYL-TRICHLOROETHANE (DDT) CAS: 50-29-3; Chemical Formula: C14H9Cls H.S. No. 1113

OSHA's existing limit for dichlorodiphenyltrichloroethane (DDT) in general industry, construction, and maritime is 1 mg/m3 as an 8-hour TWA. with a skin notation. There is no limit in agriculture. The ACGIH has the same 8hour TWA limit for DDT, without a skin notation. NIOSH considers DDT a potential occupational carcinogen and recommends reducing exposure to the lowest feasible concentration, which is the lowest reliably detectable concentration (currently 0.5 mg/m9 TWA). The Agency is proposing an 8hour TWA limit of 1 mg/m3, and a skin notation, for DDT in agricultural operations.

Although DDT is banned in the United States, this substance is still widely used in other countries (Hayes 1982, p. 182). OSHA is proposing to extend the same limit currently in effect in other sectors to agriculture to achieve the primary goal of this rulemaking, which is consistency in permissible exposure limits across sectors. Workers in this sector would thus be protected in the unlikely event that DDT use is permitted at some time in the future.

DDT is a noncombustible, colorless to white powder with a slightly aromatic odor. Before being banned, DDT was a widely used insecticide.

DDT affects the nervous system. causing convulsions, tremors, and numbness. This substance also has reproductive and teratogenic effects. The oral LD50 in rats is 87 mg/kg, and the dermal LD₅₀ in rabbits is 300 mg/kg (RTECS 1990), indicating a significant degree of percutaneous absorption. Acutely poisoned animals show incoordination, excitement, muscular weakness, and convulsions before death (Clayton and Clayton 1981, p. 3688). Rats fed large oral doses of DDT show focal and centrilobular necrosis of the liver at autopsy (Hayes 1982, pp. 180-205). The liver damage associated with chronic feeding of DDT is dose-related; rats fed 100 ppm show mild liver damage at autopsy, while those fed at higher levels showed increasingly severe damage (Clayton and Clayton 1981, p. 3689). Some authors (Treon and Cleveland, 1955) have reported liver effects in rats fed 12.5 ppm DDT in the diet for 18 to 24

months. DDT has been tested for reproductive and/or embryotoxic, teratogenic, or developmental effects in rats, mice, dogs, and rabbits using oral, intraperitoneal, or subcutaneous route of administrations; the results of these studies show that DDT has both male and female reproductive effects as well as embryotoxic and developmental effects (RTECS 1990). DDT has been tested for carcinogenicity in rats, mice, hamsters, dogs, and monkeys. In mice and rats, the results of these studies were positive. The principal tumors produced by DDT were benign and malignant liver neoplasms, lymphomas, and lung neoplasms. Based on this evidence, the International Agency for Research on Cancer has concluded that the evidence for the carcinogenicity of DDT in animals is sufficient (IARC 1987. Suppl. 7, p. 187).

In humans, incidents of acute poisoning have generally occurred as a result of accidental ingestion (Hayes 1982, pp. 180-205). If the dose is sufficiently large (i.e., greater than 16 mg/kg), convulsions may occur. followed by respiratory failure and death (Hayes 1982, pp. 180-205). Involvement of the liver, as evidenced by jaundice, has been seen in some cases of accidental ingestion (Haves 1982, pp. 180-205). After a single dose or small repeated doses, DDT accumulates in adipose tissue, where it remains for long periods of time (Gosselin, Smith, and Hodge 1984, p. III-135). The significance to health of the fat storage of DDT is not known.

Concern that DDT may be carcinogenic in humans has been widespread, but the results of many studies in farmers, forestry workers, pesticide applicators, and other occupationally exposed workers have been inclusive, and interpretation even of the few positive studies are complicated by the concomitant exposure of these workers to other pesticides (IARC 1987, Suppl. 7, p. 186). Based on an evaluation of the available data in humans, IARC has concluded that the evidence for the carcinogenicity of DDT in humans is inadequate (IARC 1987, Suppl. 7, p. 186). A recent prospective follow-up study of cancer mortality in relation to serum DDT levels (Austin, Keil, and Cole 1989) concluded that there is "weak" evidence of a positive relation between respiratory cancer mortality and serum DDT levels.

Based on a review of the evidence of the health effects of exposure to DDT, OSHA preliminarily concludes that the existing PEL of 1.0 mg/m³ is adequately protective in the unlikely event of exposure to this banned substance. The Agency finds that the existing limit, with its skin notation, provides appropriate protection against DDT's systemic effects and proposes to extend this limit to agriculture to make OSHA's PEL for this substance consistent across all regulated sectors.

2-N-DIBUTYLAMINOETHANOL CAS: 102-81-8; Chemical Formula: (C₄H₉)₂NCH₂CH₂OH H.S. No. 1120

OSHA's current limit for 2-N-dibutylaminoethanol (DBAE) in construction and maritime is 2 ppm as an 8-hour TWA, with a skin notation. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 2 ppm for DBAE, with a skin notation. The Agency is proposing to retain its PEL of 2 ppm as an 8-hour TWA in construction and maritime, to delete the skin notation, and to extend the 2 ppm 8-hour TWA PEL to agriculture. NIOSH concurred (Ex. 8-47, Table N-1) with this limit when it was recently established in general industry.

2-N-Dibutylaminoethanol is a colorless, combustible liquid with a faint amine-like odor. It is used in organic synthesis (ACGIH 1986, p. 390; Hawley's 1987, p. 175).

In rats, 2-N-dibutylaminoethanol has a single-dose oral LD50 of 1.7 g/kg and an intraperitoneal LDso of 0.14 g/kg; these values are approximately analogous to the oral and intraperitoneal LDsos for diethanolamine (Hartung and Cornish 1968/Ex. 1-328). The dermal LDso for DBAE in rabbits is 1.68 g/kg (Smyth. Carpenter, Weil, and Pozzani 1954/Ex. 1-440). In male rats, the lowest 5-week drinking water dose tolerated without weight loss was 0.13 g/kg/day. Rats that ingested a dose of 0.43 g/kg/day showed elevated kidney-to-body-weight ratios but no histologic changes at autopsy (Cornish, Dambrauskas, and Beatty 1969/Ex. 1-411). In inhalation studies of rats, 6-hour exposures at 70 ppm for 5 days killed one rat; the surviving rats showed a 57-percent average body weight loss, as well as a doubling of kidney-to-body-weight ratios, a tenfold increase in serum bilirubin, a slight increase in clotting time, and an elevated hematocrit. Inhalation of 33 ppm for 1 week caused a 3-percent body weight loss and a slight increase in clotting time, but no significant changes in the other variables observed. Twentyseven weeks of exposure to 22 ppm resulted in no differences between exposed rats and controls in the variables measured (Cornish, Dambrauskas, and Beatty 1969/Ex. 1-411). 2-N-Dibutylaminoethanol is a more potent inhibitor of acetylcholinesterase

in vitro than is diethylamine (DEA) (Hartung and Cornish 1968/Ex. 1-328).

OSHA is retaining its 8-hour TWA PEL of 2 ppm for 2-Ndibutylaminoethanol in construction and maritime, and deleting the skin notation; in agriculture, OSHA is proposing an 8hour TWA PEL of 2 ppm for DBAE. The Agency preliminarily concludes that this limit will protect workers in agriculture from the significant risk of metabolic effects associated with inhalation exposure at the levels permitted in the absence of an OSHA limit. OSHA believes that this substance does not present a significant risk of systemic toxicity via percutaneous absorption, and the skin notation is therefore not being retained in construction and maritime. Promulgation of the 8-hour TWA limit in agriculture will make OSHA's PEL for this substance consistent across all regulated sectors.

DIELDRIN
CAS: 60-57-1; Chemical Formula:
C₁₂H₈Cl₆O

H.S. No. 2061

In general industry, construction, and maritime, OSHA's current TWA-PEL for dieldrin is 0.25 mg/m³, with a skin notation. The NIOSH REL for this substance is the lowest detectable limit; the REL is based on dieldrin's carcinogenicity in animals. The ACGIH TLV*-TWA is 0.25 mg/m³, with a skin notation. OSHA is proposing an 8-hour TWA PEL of 0.25 mg/m³, and a skin notation, for dieldrin in agricultural workplaces. This action will make the PEL consistent across all OSHA-regulated sectors.

Dieldrin, also called HEOD, Octalox*, Panoram*, and Quintox*, is a light brown, nonflammable solid. It is a cyclodiene insecticide that was formerly used extensively in the soil treatment of agricultural fields; it also found widespread use in malaria control (Hayes 1982, pp. 237–238). Dieldrin is stable and highly persistent in the environment (EPA 1987, ODW Health Advisory). All uses of dieldrin have been canceled or suspended in the United States (Farm Chemicals Handbook 1990). OSHA thus anticipates

that exposure to this substance will be minimal; the PEL is being proposed to achieve the primary objective of this rulemaking: consistency in limits across all OSHA-regulated sectors.

Dieldrin is a convulsant in humans and animals; it also causes cancer and fetotoxicity in animals. The oral LD₅₀s in rats and monkeys are 38 mg/kg and 3 mg/kg, respectively (EPA 1987, p. 4). The dermal LD₅₀ in rabbits is reported to range from 150 to 450 mg/kg (Hayes 1982, p. 238). Acutely poisoned animals

convulsed before death (Haves 1982, pp. 238-240). Rats fed dieldrin over a 2-year period developed hemorrhagic or distended urinary bladders (often associated with nephritis) or increases in liver to body weight ratios and pathological changes in the liver (Fitzhugh et al. 1964; Lehman 1959; in EPA 1987, p. 4). Dogs given dieldrin at dietary doses of between 0.2 and 10 mg/ kg 6 days/week for as long as 25 months lost weight and had convulsions (Fitzhugh et al. 1964); other dogs given dieldrin by capsule for 2 years at doses of 0.005 or 0.05 mg/kg/day had increases in liver weights and in liver to body weight ratios (Walker et al. 1969, in EPA 1987, p. 5). Dietary administration of dieldrin to mice at doses between 1.25 and 20 ppm for 128 weeks caused a high rate of mortality in the high-dose group and palpable intra-abdominal masses in animals from the 10, 5, and 2.5-ppm groups (Walker et al. 1972, in EPA 1987, p. 5). No liver enlargement occurred in the 1.25-ppm group (Walker et al. 1972). Two carcinogenicity bioassays in mice were positive; dieldrin-exposed animals in both studies developed hepatocellular carcinomas and other liver tumors (Walker et al. 1972; Lehman 1959, in EPA 1987). Several studies in hamsters and mice have shown dieldrin to be teratogenic and embryocidal when administered to pregnant animals (Ottolenghi et al. 1974; Chernoff et al. 1975, in EPA 1987, pp. 5-6).

There have been several fatal accidental poisonings involving dieldrin in humans; the oral dose estimated to be lethal is 5 grams (Hayes 1982, p. 243; Hodge, Boyce, Deichmann, and Kraybill 1967, in ACGIH 1986, p. 196). Occupational poisonings have been reported in applicators and farmers and among workers manufacturing and formulating this substance (Hayes 1982, p. 243). Many of the reported poisoning episodes (between 47 and 100 percent) involved convulsions (Hayes 1982, p. 244). Other signs and symptoms of dieldrin poisoning are headache, nausea, vomiting, a feeling of malaise, dizziness, and muscle jerking (Hayes 1982, p. 244). Most workers who were poisoned recovered completely after treatment (Hayes 1982, p. 244).

Based on this evidence in humans and animals, OSHA preliminarily concludes that exposure to dieldrin poses a significant occupational risk and that establishment of the proposed PEL is necessary to ensure consistency in the PEL for dieldrin across all OSHA-regulated sectors. Because dieldrin has been banned for use in the United States, OSHA believes that exposure to this substance will be minimal.

DIFLUORODIBROMOMETHANE CAS: 75–61–6; Chemical Formula: CBr₂F₂ H.S. No. 2063

In general industry, construction, and maritime, OSHA's PEL for difluorodibromomethane is 100 ppm as an 8-hour TWA. The ACGIH TLV*_
TWA for this substance is also 100 ppm. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 100 ppm for difluorodibromomethane in agriculture. This action will make the PEL for this substance consistent across all OSHA-regulated sectors.

Difluorodibromomethane (also called Freon 12B2) is a colorless, nonflammable liquid that is used primarily as a fire extinguishant (ACGIH 1986, p. 210). It is also used in the synthesis of dyes, pharmaceuticals, and ammonium compounds (Hawley's

1987, p. 368).

Difluorodibromomethane is a respiratory irritant on acute exposure and a central nervous system and liver toxin on chronic exposure (Cralley and Cralley 1985, p. 166). The 15-minute LC50 in rats is 55,000 ppm (ACGIH 1986, p. 201). Rats exposed to a 4000-ppm concentration of difluorodibromomethane for 15 minutes showed signs of pulmonary irritation and developed pulmonary edema (ACGIH 1986, p. 201). Dogs and rats exposed for 6 weeks to a difluorodibromomethane concentration of 2300 ppm showed the following exposure-related effects: mortality in 50 percent of the rats and weakness, incoordination, and signs of increasing intoxication in the dogs after a few days of exposure. At autopsy, neurological and hepatic damage was evident (ACGIH 1986, p. 201).

There are no reports of difluorodibromomethane-induced toxicity from industrial use. The thermal decomposition products generated during the use of difluorodibromomethane as a fire extinguishant, however, have caused tinnitus, paresthesia, anxiety reactions, electroencephalographic changes, slurred speech, and decreased psychological test performance in firefighters and other exposed individuals (Clayton and Clayton 1981, p. 3107).

Based on this evidence, OSHA preliminarily concludes that an 8-hour PEL of 100 ppm is necessary in agriculture both to protect exposed agricultural workers from difluorodibromomethane's irritant and systemic effects and to make OSHA's limit for this substance consistent across

all OSHA-regulated sectors.
Accordingly, OSHA is proposing an 8-hour TWA of 100 ppm for difluorodibromomethane in agriculture. The Agency believes that this limit will reduce the significant risk of these material health impairments substantially.

DIGLYCIDYL ETHER (DGE)
CAS: 2238-07-5; Chemical Formula:
C6H10O3
H.S. No. 1139

The current OSHA limit for diglycidyl ether (DGE) in construction and maritime is 0.5 ppm as a ceiling concentration. There is no limit in agriculture. The ACGIH-recommended TLV ® for this substance is 0.1 ppm as an 8-hour TWA. NIOSH considers this substance a potential occupational carcinogen and recommends a limit of 0.2 ppm for DGE as a 15-minute ceiling; however, NIOSH concurred (Exs. 8-47, Table N6A) with the limit being proposed when it was recently established for DGE in general industry. OSHA is proposing an 8-hour TWA PEL of 0.1 ppm for DGE in the construction, maritime, and agriculture industries.

Diglycidyl ether is a colorless liquid with a strong, irritating odor. It is used primarily as a chemical intermediate (ACGIH 1986, p. 202; Hawley's 1987, p.

398).

Both the previous ACGIH 0.5-ppm TLVT4 ® and that organization's current TLVT4® are based on the results of an animal study reported by Hine and Rowe (1963b, as cited in ACGIH 1986/ Ex. 1-3, p. 202) in which rats were administered repeated 4-hour exposures of 20, 3, or 0.3 ppm DGE. Rats exposed to 20 ppm of DGE showed respiratory irritation, loss of body weight, decreased leukocyte count, involution of the spleen and thymus, and hemorrhagic bone marrow. Residual hematopoietic effects were observed among rats exposed to 3 ppm, and no observed effects were noted among rats exposed to 0.3 ppm, even after as many as 60 exposures. The ACGIH's previous TLVT4® of 0.5 ppm as a ceiling value was based on the noobserved-effect level of 0.3 ppm reported in the Hine and Rowe (1963b, as cited in ACGIH 1986/Ex. 1-3, p. 202) study and on industrial experience. In 1979, the ACGIH reconsidered its limit for DGE, noting that, "in view of the seriousness of some of the effects produced [in the rat study], a TLVT4® below the no-illeffect level [of 0.3 ppm] would normally be adopted" (ACGIH 1986/Ex. 1-3). The ACGIH consequently revised the TLVT4 ® to 0.1 ppm as an 8-hour TWA. NIOSH agrees that a PEL of 0.1 ppm is appropriate for DGE but notes that this substance meets the criteria for a

potential occupational carcinogen (Ex. 8–47, Table N6A).

OSHA preliminarily concludes that the proposed 8-hour TWA limit of 0.1 ppm will protect workers in construction, maritime, and agriculture from the significant risk of DGE-induced hematopoietic and irritant effects, which constitute material health impairments within the meaning of the Act. The risks of DGE exposure range from respiratory irritation to bone marrow effects, and OSHA believes that the proposed limit for DGE will reduce these risks substantially. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

DIISOPROPYLAMINE CAS: 108–18–9; Chemical Formula: (CH₃)₂CH-NH-(CH₃)₂ H.S. No. 2064

OSHA's current limit for disopropylamine in construction, maritime, and general industry is 5 ppm as an 8-hour TWA, with a skin notation. NIOSH has no REL but concurs (Ex. 8–47, Table N3A) with the limit being proposed. OSHA is proposing to establish an 8-hour TWA PEL of 5 ppm, and a skin notation, for this substance in agriculture. This action will make OSHA's PEL for disopropylamine consistent across all OSHA-regulated sectors.

Diisopropylamine is a colorless, volatile liquid with a fishy, amine-like odor (ACGIH 1986, p. 204). This substance is used as an intermediate in the production of pesticides, pharmaceuticals, and other chemicals, as a catalyst, and as an experimental hypertensive drug (HSDB 1986). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Diisopropylamine is an irritant of the eyes and upper respiratory tract in humans and animals. The oral LD50 in rats is 770 mg/kg, and the LC50 in the same species is 4800 mg/m3 (800 ppm) for 2 hours (RTECS 1990). Instilled into rabbit eyes, this substance caused severe irritation (RTECS 1990). Experimental animals (guinea pigs, rabbits, cats, and rats) exposed to a 2207-ppm concentration of diisopropylamine for 3 hours died; before death, these animals exhibited corneal clouding, tearing of the eyes, and signs of severe respiratory irritation. At autopsy, pulmonary edema and hemorrhage were evident (Proctor, Hughes, and Fischman 1988, p. 205). Exposure of animals of the same species to a 777-ppm concentration of

diisopropylamine, however, was not fatal (ACGIH 1986, p. 204).

Workers exposed to concentrations of diisopropylamine of 25 to 50 ppm reported experiencing hazy vision, a symptom indicating corneal edema (Treon, Sigmon, Kitzmiller, and Heyroth 1949, in Proctor, Hughes, and Fischman 1988, p. 205). In addition, some workers experienced nausea and headache (Treon et al. 1949). Because diisopropylamine is highly alkaline, prolonged skin contact with this substance is likely to cause dermatitis (Clayton and Clayton 1981, p. 3155).

Based on this evidence in humans and animals, OSHA preliminarily concludes that exposure to diisopropylamine at the concentrations possible in the absence of an exposure limit poses a significant risk of primary irritation to agricultural workers. The Agency considers this effect a material impairment of health and believes that the proposed limit will substantially reduce this risk. Accordingly, OSHA is proposing an 8hour TWA of 5 ppm, and a skin notation, for diisopropylamine in agriculture. Promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

DIMETHYLFORMAMIDE
CAS: 68-12-2; Chemical Formula:
HCON(CH₃)₂
H.S. No. 2067

In general industry, construction, and maritime, OSHA's current limit for dimethylformamide is 10 ppm (30 mg/m³) as an 8-hour TWA; there is also a skin notation for this substance. There is no PEL in agriculture. The ACGIH has a TLV®-TWA for dimethylformamide of 10 ppm, with a skin notation. NIOSH has no REL for this substance. OSHA is proposing an 8-hour TWA PEL of 10 ppm, and a skin notation, for dimethylformamide in agriculture. Promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

Dimethylformamide is a colorless to light yellow flammable liquid that has a faint ammonia-like odor. It is used primarily as a solvent for polar polymers. It is commonly found in paint removers and is used in selective gas absorption and solvent extraction operations. Dimethylformamide is also used as a co-solvent or booster in protective coatings, adhesives, films, and printing inks (Merck 1983, p. 473; ACGIH 1986, p. 209).

Dimethylformamide is a liver, kidney, lung, and cardiovascular toxin in humans and animals. Exposure to this substance also has been associated with

testicular cancer in humans and reproductive effects in animals. The oral LDso in rats is 2900 mg/kg, and the LCso in mice is 9400 mg/m3 for 2 hours (RTECS 1990). The dermal LD50 in rabbits is 4720 mg/kg (RTECS 1990). Instilled into the eyes of rabbits, dimethylformamide caused a moderate degree of irritation; in contact with the skin, this substance caused mild irritation (Grant 1986, p. 348; RTECS 1990). A single 6-hour exposure to 5000 ppm dimethylformamide, or five 6-hour exposures to 2500 ppm, killed all exposed rats; at autopsy, damage to the liver, kidneys, and lungs was evident (E.I. du Pont de Nemours and Co., Inc. 1976, in ACGIH 1986, p. 289). Repeated oral dosing of rats with dimethylformamide (at doses of 450 mg/ kg) caused reversible decreases in the rate of body weight gain and liver injury (Kennedy et al. 1986, in Drug Chem. Toxicol. 9(2):147-170). In a 90-day feeding study in rats, a dietary level of 1000 ppm caused slight anemia and an increase in white blood cell counts. while a dietary level of 200 ppm caused no observable effects. Carcinogenicity bioassays in rats by the oral or subcutaneous routes of administration were negative (Druckry, H. et al. 1967, in ACGIH 1986, p. 289). Although dimethylformamide appears not to be teratogenic, inhalation exposure of pregnant rats caused a substantial decrease in fertility, an increase in intrauterine deaths, and a decrease in embryo weight (Gofonckler 1974, in Gigiena i Sanit. 9:7-10). Injected intratesticularly, 0.1 ml of dimethylformamide had arrested spermatogenesis 2 and 7 days after exposure; the testicular epithelium had also become disorganized and white cell infiltration had occurred (Saxena et al. 1985, in J. Toxicol. Environ. Hlth. 15(3-4):583-587). Dimethylformamide is generally not mutagenic in bacterial assays (Kennedy 1986, in CRC Critical Reviews in Toxicol. 17(2):129-182).

In humans, exposure to dimethylformamide causes mild skin irritation, headaches, gastrointestinal symptoms, and cardiovascular effects. as well as kidney and liver damage; exposure has also been associated with testicular and other cancers. This substance also interacts with alcohol to cause an Antabuse®-like reaction. Symptoms of exposure in a worker splashed with liquid dimethylformamide over 28 percent of his body surface area included skin irritation, abdominal pain and vomiting, and elevated blood pressure, all of which resolved completely within 7 days of exposure (Proctor, Hughes, and Fischman 1988, p.

210). Other workers exposed to dimethylformamide have reported abdominal pain, nausea, and vomiting (ACGIH 1986, p. 209). Ingestion of alcohol up to 4 days following inhalation exposure to dimethylformamide may cause facial flushing and palpitations (Genium MSDS 1982, No. 424). A casecontrol study of 100 workers exposed to a mean concentration of dimethylformamide of 22 mg/m3 matched with 100 controls showed that reports of headache and dyspepsia and an elevated liver injury enzyme (gammaglutaryl transferase) were associated specifically with chronic dimethylformamide exposure (Cirla, AM et al. 1984, G. Ital. Med. Lav. 6:149-156). Chronic skin contact with this substance also may cause dermatitis (Proctor, Hughes, and Fischman 1988, p. 210). After a case of symptomatic hepatitis developed in a clothing factory worker, further investigation revealed that 36 of 58 workers tested had elevated liver enzymes. Serologic tests excluded infectious causes in 34 of these 36 workers. The results of liver biopsies in four of these workers demonstrated histological changes characteristic of toxic liver damage. Modification of work hygiene practices was associated with decreased liver enzyme levels (Redlich CA et al. 1988, Annals of Internal Medicine 108:680-686). Three cases of testicular cancer were reported in leather tanners exposed to dimethylformamide; the onset occurred after latency periods of 8 to 14 years (Levin et al. 1987, Lancet 11(8568):1154). A cluster of three cases of testicular cancer among 153 white male aircraft repair employees exposed to dimethylformamide led to the identification of four additional cases among 680 employees at a second, occupationally identical site, a statistically significant increase over national testicular cancer incidence rates. The additional finding that the average age of the identified cases was the average age of all employees and not the peak age for testicular cancer suggests an occupational etiology (Ducatman AM et al. 1986, Journal of Urology 136(4):834-836). Among workers followed from 1954 to 1984 for cancer incidence, dimethylformamide exposure was also associated with excess mouth cancers and malignant melanomas. Combined dimethylformamide and acrylonitrile exposure was associated with increased rates of prostate cancer: no dose-response effects were noted for these cancers, however (Chen JL et al. 1988, Journal of Occupational Medicine 30(10):813-818). Another study showed an excess of several cancers, but not

testicular cancer, associated with dimethylformamide exposure. The authors suggested that, as a readily absorbed solvent, dimethylformamide may act to increase the absorption of other potentially carcinogenic compounds such as chromium- and cadmium-based dyes (Ducatman AM 1989, Lancet 1[8643]:911].

Based on this evidence in humans and animals, OSHA is proposing a 10-ppm 8hour TWA PEL, and a skin notation, for dimethylformamide in agriculture. The Agency preliminarily concludes that this limit is necessary to substantially reduce the significant risks of kidney. liver, lung, and cardiovascular damage. as well as cancer, associated with exposure to this substance. OSHA believes that each of these effects constitutes a material impairment of health and that the proposed PEL is necessary to substantially reduce these risks. In addition, promulgation of this limit will make OSHA's PEL for dimethylformamide consistent across all regulated sectors.

1,1-DIMETHYLHYDRAZINE
CAS: 57-14-7; Chemical Formula:
(CH₃)₂NNH₂
H.S. No. 2068

In construction, maritime, and general industry, OSHA's TWA PEL for 1,1dimethylhydrazine is 0.5 ppm; there is also a skin notation for this substance. There is no PEL in agriculture. The 1987-1988 ACGIH TLV®-TWA for this substance was 0.5 ppm, with a skin notation. The ACGIH also assigns this substance an A2 designation (suspected human carcinogen). The NIOSH REL for 1,1-dimethylhydrazine is 0.06 ppm as a 2-hour ceiling; this represents the lowest concentration that can be detected analytically. OSHA is proposing to establish a PEL of 0.5 ppm as an 8-hour TWA, with a skin notation, for 1,1dimethylhydrazine in agriculture. This action will make the PEL for this substance consistent across all OSHAregulated sectors.

1,1-Dimethylhydrazine, also called asym- or unsymmetrical dimethylhydrazine, is used as an intermediate in chemical synthesis, an ingredient in photographic chemicals, a stabilizer for fuel additives, a plant growth regulator, and a component of jet and rocket fuels (ACGIH 1986, p. 210.1(89); Clayton and Clayton 1981, p. 2792). 1,1-Dimethylhydrazine is a flammable, colorless liquid with an ammonia-like odor; it fumes in air and gradually turns yellow (ACGIH 1986, p. 210.1(89)).

1,1-Dimethylhydrazine causes systemic toxicity in the form of central

nervous system effects, hematological effects, and, in animals, cancer. The 4hour LC50 in rats is 250 ppm, and the occluded dermal LD50 in rabbits is 156 mg/kg (ACGIH 1986, p. 210.1(89); RTECS 1990). In monkeys, inhalation of a 162ppm concentration proved lethal within 1 hour (Clayton and Clayton 1981, p. 2802). Acutely poisoned animals convulsed and vomited before death; autopsy revealed pulmonary edema and hemorrhage (NIOSH Criteria Document (Hydrazines) 1976). Dogs exposed repeatedly to a 25-ppm concentration developed ataxia, diarrhea, vomiting, excessive salivation, depression, convulsions, and hemolytic anemia (Clayton and Clayton 1981, p. 2802). Thirty seconds after application to the skin of dogs, 1,1-dimethylhydrazine was detectable in the blood, and exposure by this route also led to corneal opacities (Smith and Clark 1971; Smith and Castaneda 1970, in ACGIH 1986, p. 210.1(89)). This substance causes embryotoxicity when administered intraperitoneally to rats during pregnancy (Keller et al. 1984, in Proctor, Hughes, and Fischman 1988, p. 212). Administered to mice, rats, and hamsters in the drinking water, 1,1dimethylhydrazine caused a high incidence of angiosarcomas and tumors of the lung, kidney, and liver in mice, liver carcinomas in rats, and vascular and cecal tumors in hamsters. Inhalation bioassays in mice and rats exposed to 0.5 or 5 ppm 1,1-dimethylhydrazine also were positive (ACGIH 1986, p. 210.1(89); IARC 1974, Vol. 4, pp. 137-143). Based on its tumorigenicity in animals, this substance is considered an animal carcinogen by the International Agency for Research on Cancer, NIOSH, the National Toxicology Program, and the American Conference of Governmental Industrial Hygienists.

In humans, accidental exposure to 1,1dimethylhydrazine at unknown concentrations has caused eye and skin irritation, nausea, chest pain, difficult breathing, a choking sensation, and lethargy (Shook and Cowart 1957, in Proctor, Hughes, and Fischman 1988, p. 212). Eleven workers accidentally overexposed to 1,1-dimethylhydrazine showed signs of liver involvement in laboratory tests but did not develop clinical signs or symptoms (Shook and Cowart 1957). In another group of 26 workers engaged in the production of rocket fuels (and thus exposed to unspecified concentrations of 1,1dimethylhydrazine), six cases of fatty liver, evidenced by a rise in SGPT levels, occurred (IARC 1974, Vol. 4, p.

Based on this evidence in humans and animals, OSHA preliminarily concludes that workers in agriculture are at significant risk of experiencing the serious and potentially life threatening effects of exposure to 1,1dimethylhydrazine. OSHA believes that these effects, which include sensory irritation and liver damage, constitute material health impairments. Accordingly, OSHA is proposing an 8hour TWA PEL of 0.5 ppm, with a skin notation, for this substance in agriculture. Promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. DINITRO-O-CRESOL CAS: 534-52-1; Chemical Formula: CH3C6H2OH(NO2)2

H.S. No. 2070

In general industry, construction, and maritime, OSHA's permissible exposure limit for dinitro-o-cresol is 0.2 mg/m3 as an 8-hour TWA; this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 0.2 mg/m3 as an 8-hour TWA, and a skin notation, for dinitro-o-cresol, and NIOSH has a REL of 0.2 mg/m3 as a 10-hour TWA. OSHA is proposing an 8-hour TWA PEL of 0.2 mg/m3, and a skin notation, for dinitro-o-cresol in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Dinitro-o-cresol (DNOC) is an odorless, yellow, crystalline solid. It is used as a selective herbicide and plant growth regulator (Hazardous Substance Fact Sheet 1986, p. 1; Gosselin, Smith, and Hodge 1984, p. II-196). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Exposure to dinitro-o-cresol causes metabolic stimulation and yellow pigmentation of the skin, eyes, and hair, and severe exposure can cause coma and death in humans and animals. In rats, the oral LD50 is 31 mg/kg, and in rabbits, it is 23.5 mg/kg (ACGIH 1986, p. 215; RTECS 1990). In rats, the dermal LD50 is 200 mg/kg (RTECS 1990). Cats survived one 4-hour exposure to the vapors of dinitro-o-cresol at a concentration of 1.4 mg/m3 however, one of three cats died from a single exposure to a concentration of 40 mg/m3 (Burkatskaya 1965, in ACGIH 1986, p. 215). The signs and symptoms of dinitroo-cresol intoxication are similar in all species and include listlessness, loss of

appetite and activity, deep, rapid respiration, sweating, thirst, oliguria. muscular weakness, prostration, dyspnea, and death with terminal hyperpyrexia; signs may be delayed for several hours (Clarke 1981, in HSDB 1990). When about 70 mg/kg of dinitroo-cresol was given orally to sheep, toxic effects were observed in the liver and kidneys; moderate methemoglobinemia and hemoconcentration were also seen. Of the nine sheep dosed, three survived; all suffered extensive hemolysis followed by anemia (Nehez et al. 1981, in HSDB 1990). Cats subjected to daily 4hour exposures of 0.2 mg/m3 DNOC for 3 months suffered from sluggishness, loss of muscle tone, dyspnea, a decrease in hemoglobin and red blood cell counts, and an increase in white blood cell counts and blood sugar levels; three cats died (Burkatskaya 1965, in ACGIH 1986,

Dinitro-o-cresol exerts its effects by stimulating the metabolic rate and causing hyperpyrexia; if heat production exceeds heat loss, fatal hyperthermia may occur. In humans, the signs and symptoms of acute exposure to dinitroo-cresol are nausea, gastric upset, restlessness, a sensation of heat, flushed skin, sweating, rapid respiration, tachycardia, fever, cyanosis, and coma (Klaassen, Amdur, and Doull 1986, p. 556). The lowest toxic oral dose in humans is 7500 µg/kg for 7 days; at this level, the exposed individual experienced somnolence and headache (RTECS 1990). The lowest toxic concentration in humans is 1 mg/m3 (RTECS 1990). A single oral dose of 75 mg caused no adverse effects in five volunteers, but two volunteers who received this dose for 5 or more days experienced headaches, lassitude, and malaise; these symptoms occurred when the volunteers' dinitro-o-cresol blood levels reached 20 µg/g or peaks of 40 and 48 µg/g (Harvey, Bidstrup, and Bonnell 1951, in Proctor, Hughes, and Fischman 1988, p. 217). Application of 50 g of an ointment containing 25 percent dinitro-o-cresol to the skin of a 4-yearold boy produced symptoms of vomiting, headache, yellow stained skin and sclera, elevated pulse and respiratory rate, unconsciousness, and death within 3.5 hours (Buchinskiy 1974, in Hayes 1982, p. 469; NIOSH Dinitro-o-cresol Criteria Document 1978). Acute poisoning from dinitro-o-cresol is usually quick; almost complete recovery or death occurs within 24 to 48 hours (Bidstrup and Payne 1951, in Hayes 1982, p. 469). Eight fatalities have been reported in British agricultural workers spraying this substance; death occurred within 48 hours and was caused by

hyperthermia (Bidstrup and Payne 1951). In fatal cases, autopsy shows yellow staining of the organs, tissues, and fluids, congestion of the lungs, edema and a few petechial hemorrhages, and hemorrhagic changes in the brain and gastric mucosa (Bidstrup and Payne 1951, in Hayes 1982, p. 470). Repeated ingestion of dinitro-o-cresol for therapeutic purposes has caused bilateral cataracts, but workers exposed to this substance in agricultural or industrial applications have not shown this effect (NIOSH Dinitro-o-cresol Criteria Document 1978).

Based on this evidence in humans and animals, OSHA preliminarily concludes that dinitro-o-cresol causes yellow pigmentation, hyperpyrexia, and central nervous system effects in humans and animals. OSHA believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that establishing a permissible exposure limit of 0.2 mg/m3 as an 8-hour TWA, with a skin notation, for dinitro-o-cresol in agriculture is necessary to substantially reduce the risk of these material health impairments. In addition, establishing the proposed limit in agriculture will make OSHA's PEL for dinitro-o-cresol consistent across all OSHA-regulated sectors.

ETHANOLAMINE
CAS: 141-43-5; Chemical Formula:
NH2CH2CH2OH
H.S. No. 1159

OSHA currently has an 8-hour TWA limit of 3 ppm for ethanolamine in construction and maritime. There is no limit in agriculture. The ACGIH has the same TLV*-TWA limit of 3 ppm, along with a 15-minute STEL of 6 ppm. In construction and maritime, OSHA is retaining the 8-hour TWA PEL of 3 ppm and proposing to supplement this limit with a 6-ppm STEL. OSHA is also proposing to extend both limits to agriculture. NIOSH has no REL but concurred (Ex. 8-47, Table N1) with the proposed limits when they were recently established for ethanolamine in general industry.

Ethanolamine is a colorless liquid with a mild smell like that of ammonia. Ethanolamine is used in agriculture as a chemical (pesticide) dispersing agent and is also used in the manufacture of antibodies. This substance is also used in chemical synthesis and as an ingredient in emulsifiers, polishes, and waving solutions for hair (ACGIH 1986, p. 235; Hawley's 1987, p. 474). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal

Insecticide, Fungicide, and Rodenticide Act (FIFRA).

The health hazards associated with exposures to ethanolamine include irritation and necrosis of the skin and central nervous system depression. The oral LD50 in rats is 3.32 g/kg, and the intraperitoneal LD50 in rats is 981 mg/kg (Hartung and Cornish 1968/Ex. 1-328). The dermal toxicity of ethanolamine is considerably higher, with an LDso of 1 mg/kg reported in the rabbit. Dermal application of the undiluted liquid also caused redness, swelling, and burns comparable to mild first-degree burns (Union Carbide Corporation, as cited in ACGIH 1986/Ex. 1-3, p. 235). The eye injury potential of ethanolamine is just slightly less than that of undiluted ammonia (Carpenter and Smyth 1946/ Ex. 1-859). Rats fed 0.5 percent (320 mg/ kg/day) ethanolamine in their food for 90 days (Smyth, Carpenter, and Weil 1951/Ex. 1-439) showed no adverse effects, but at 1.28 g/kg/day, fatalities occurred. Treon, Cleveland, Stemmer, and associates (1957/Ex. 1-1172) reported lung, liver, and kidney damage in various species exposed to high concentrations of the vapor and mist. In tests of various species, Weeks and coworkers (1960/Ex. 1-941) reported marked dermal effects from continuous exposures (24 hours/day, 7 days/week, for from 24 to 90 days) at various concentrations of the vapor; at 12 to 26 ppm, dermal effects were less severe. but at 5 ppm, skin irritation was still evident. After 90 days of exposure to 5 ppm, dogs experienced a slight and temporary weight loss as well as decreased activity and alertness (Weeks, Downing, Musselman et al. 1960/Ex. 1-941). In studies of anesthetized dogs, Priddle (1954, as cited in ACGIH 1986/Ex. 1-3, p. 235) reported that sublethal doses of ethanolamine cause central nervous system stimulation, while lethal doses cause CNS depression.

OSHA is retaining its PEL of 3 ppm as an 8-hour TWA in construction and maritime, is proposing to add a 15minute STEL of 6 ppm for ethanolamine in these industries, and is also proposing to extend both PELs to agriculture. The Agency preliminarily concludes that both of these limits are required to protect workers against the significant risk of irritation and central nervous system effects, which constitute material health impairments that are potentially associated with exposure to. ethanolamine. The Agency believes that these limits will substantially reduce these significant risks. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

ETHYLENE CHLOROHYDRIN CAS: 107-07-3; Chemical Formula-CICH₂CH₂OH H.S. No. 1167

OSHA currently has an 8-hour TWA limit of 5 ppm, with a skin notation, for ethylene chlorohydrin in construction and maritime. There is no limit in agriculture. The ACGIH has a TLV*-ceiling of 1 ppm, also with a skin notation. The Agency is proposing a PEL of 1 ppm as a ceiling, with a skin notation, for this substance in construction, maritime, and agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the proposed limit, which is the PEL recently established for ethylene chlorohydrin in general industry.

Ethylene chlorohydrin is a colorless liquid with a faint, ethereal odor. It is used in the manufacture of insecticides, as a solvent in organic synthesis, and to activate sprouting of dormant potatoes (Hawley's 1987, p. 485, ACCIH 1986, p. 248). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

A broad range of serious health hazards are associated with exposure to this substance; these include central nervous system effects, cardiovascular effects, liver damage, kidney damage, gastrointestinal effects, skin irritation, eye irritation, and mutagenic effects. The oral LD₅₀ for rats is 72 mg/kg, and the intraperitoneal LD₅₀ in the same species is 56 mg/kg (Goldblatt and Chiesman 1944/Ex. 1–980). In guinea pigs, the intraperitoneal LD₅₀ is 98 mg/kg, and the percutaneous LD₅₀ is 205 mg/kg (Wahlberg and Boman 1978/Ex. 1–938).

The inhalation toxicity of ethylene chlorohydrin is also high. Ambrose (1950/Ex. 1–888) reported that a single 1-hour exposure to 7.5 ppm and repeated 1-hour exposures to 2 ppm can be fatal to rats. Exposures of 15 minutes daily at concentrations of from 900 to 1000 ppm were fatal to rats within a few days (Goldblatt and Chiesman 1944/Ex. 1–980).

In subacute and chronic studies, rats have died from a daily dietary dose of 67.5 mg/kg (Oser, Morgareidge, Cox, and Carson 1975/Ex. 1–923). Semenova and associates (1980, as cited in ACGIH 1986/Ex. 1–3, p. 248) reported a 4-month no-effect inhalation level of 0.0033 ppm; at 0.017 ppm, slight CNS changes and alterations in the urinary excretion of nitrogen were observed after 4 months. These investigators also observed increased chromosomal aberrations in the bone marrow in rats exposed at the

0.22-ppm level for 4 months (Semenova, Kazanina, Fedyanina et al. 1980, as cited in ACGIH 1986/Ex. 1-3, p. 248).

Voogt and Vet (1969/Ex. 1-1205) tested ethylene chlorohydrin in Klebsiella pneumoniae and found it strongly mutagenic. This finding was confirmed by the Ames test in Salmonella typhimurium; ethylene chlorohydrin reacts with DNA, since it inhibits the growth of DNA-deficient bacteria (Rosenkranz and Włodkowski 1974/Ex. 1-1201). A dose-related increase of liver protein and depletion in glutathione were observed in rats after a single dose of ethylene chlorohydrin ranging from 10 to 50 mg/kg (Friedman, Scalera, Balazs et al. 1977/Ex. 1-1198).

One fatal and several nonfatal cases of poisoning in industrial workers have been reported from exposure (for unspecified periods of time) to ethylene chlorohydrin at levels of between 300 and 500 ppm. An autopsy of the worker who died revealed severe damage to the liver and brain, as well as effects on other organs. The survivors of this incident experienced nausea, vomiting, and irritation of the eyes, nose, and lungs (Bush, Abrams, and Brown 1949/ Ex. 1-1196). Dierker and Brown (1944/ Ex. 1-1197) reported that a 2-hour inhalation exposure to 300 ppm was fatal in one accidental exposure.

OSHA is proposing a ceiling limit of 1 ppm for ethylene chlorohydrin in construction, maritime, and agriculture, with a skin notation. The Agency preliminarily concludes that this limit and notation will substantially reduce the significant risks of central nervous system and other systemic effects associated with workplace exposures to ethylene chlorohydrin. The skin notation is necessary because ethylene chlorohydrin is readily absorbed through the skin. Promulgation of this limit also will make OSHA's PEL for this substance consistent across all regulated sectors.

ETHYLENEDIAMINE
CAS: 107-15-3; Chemical Formula:
NH₂CH₂CH₂NH₂
H.S. No. 2082

In general industry, construction, and maritime, OSHA's permissible exposure limit for ethylenediamine is 10 ppm as an 8-hour TWA. There is no limit for this substance in agriculture. The ACGIH has a TLV*-TWA of 10 ppm for ethylenediamine. NIOSH has no REL. OSHA is proposing an 8-hour TWA PEL of 10 ppm for ethylenediamine in agriculture. Promulgation of this limit will make the PEL for ethylenediamine consistent across all OSHA-regulated sectors.

Ethylenediamine is a thick, colorless, alkaline liquid with an ammonia-like odor. It is used as a fungicide; in the manufacture of chelating agents such as EDTA; as a chemical intermediate, solvent, emulsifying agent, and antifreeze inhibitor; and in textile lubricants (ACGIH 1986, p. 249; Hawley's 1987, p. 486). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Rodenticide Act (FIFRA). Ethylenediamine is an irritant of the eyes, mucous membranes, and respiratory tract and, in humans, a skin and pulmonary sensitizer. Repeated exposure causes kidney and liver damage in animals (Proctor, Hughes, and Fischman 1988, p. 241; NIOSH/ OSHA Occupational Health Guideline 1981). The oral LDso in rats is 500 mg/kg; in guinea pigs it is 470 mg/kg (RTECS 1990). The lowest lethal concentration in rats is 4000 ppm for 8 hours (RTECS 1990]. The dermal LD50 in rabbits is 730 mg/kg (Gosselin, Smith, and Hodge 1984, p. II-206]. Rabbits experienced severe irritation when 10 mg of ethylenediamine was kept in contact with their skin for 24 hours (RTECS 1990). Instilled into the eye of a rabbit, ethylenediamine caused extreme irritation and corneal damage; a 5percent solution caused partial corneal opacity (Smyth et al. 1951, in Proctor, Hughes, and Pischman 1988, p. 242). Ethylenediamine has been shown to be a potent sensitizer in guinea pigs; 10 of 10 albino guinea pigs exposed to ethylenediamine became sensitized (HSDB 1986). Rats exposed to a 4000ppm concentration of ethylenediamine for 8 hours died; however, at 2000 ppm, no deaths occurred (Smyth et al. 1951, in Proctor, Hughes, and Fischman 1988, p. 242). Daily exposure to a 484-ppm concentration of this substance for 30 days was fatal to rats; at a 132-ppm concentration on the same regimen, lung, liver, and kidney damage were seen in these animals at autopsy. although all animals survived the exposures (Pozzani 1954, in Proctor. Hughes, and Fischman 1988, p. 242). In rats exposed to 0.50 g/kg of ethylenediamine daily for two generations, a reduction in body weight and changes in liver and kidney weights were seen in the Fo and F1 parents. Microscopic liver lesions occurred with greater prevalence in the F1 female rats (Yang et al. 1984, in Proctor, Hughes, and Fischman 1988, p. 242).

In humans, exposure to a 400-ppm concentration for 5 to 10 seconds caused intolerable irritation of the nose; 200 ppm caused tingling of the face and

nasal irritation, while 100 ppm had no effect (Pozzani 1954, in Proctor, Hughes, and Fischman 1988, p. 242). The lowest toxic concentration of ethylenediamine in humans is estimated to be 200 ppm (RTECS 1990). The use of ethylenediamine in pharmaceutical preparations such as Mycolog cream has caused many cases of skin sensitization (Fisher 1973; Baer et al. 1973, in Proctor, Hughes, and Fischman 1988, p. 242). Skin patch tests conducted between 1972 and 1974 revealed that 6 percent of 3,216 patients were sensitive to a 1-percent ethylenediamine-HCl solution (North American Contact Dermatitis Group 1975, in Proctor, Hughes, and Fischman 1988, p. 242). A 30-year-old man developed asthma as a result of ethylenediamine exposure in the workplace. Two and one-half years after employment, symptoms of sneezing, nasal discharge, and cough began; these progressed over the next 5 months. Inhalation provocation tests on the worker produced chest tightness, cough, wheezing, and a 26-percent drop in FEV1 4 hours following exposure to ethylenediamine on two different days (Lam 180, in Proctor, Hughes, and Fischman 1988, p. 242).

Based on this evidence in humans and animals, OSHA preliminarily concludes that ethylenediamine causes irritation of the eyes, mucous membranes, and respiratory tract as well as skin and pulmonary sensitization. The Agency believes that, in the absence of a limit for ethylenediamine, workers in agriculture are at significant risk of experiencing these adverse health effects. OSHA believes that the proposed TWA PEL of 10 ppm will substantially reduce these risks of material health impairment. In addition. promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

FLUORIDES (as F)

CAS: Varies with compound; Chemical Formula: Varies with compound H.S. No. 2084

In general industry, construction, and maritime, OSHA's permissible exposure limit for fluorides (measured as F) is 2.5 mg/m³ as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a 2.5 mg/m³ 8-hour TLV°-TWA for these substances, NIOSH also has a REL of 2.5 mg/m³ for the fluorides as a 10-hour TWA. OSHA is proposing an 8-hour TWA PEL of 2.5 mg/m³ for the fluorides (measured as F) in agriculture.

Promulgation of this limit will make the PEL for these substances consistent across all OSHA-regulated sectors.

The physical properties of the fluorides vary for specific compounds: for example, sodium fluoride is a colorless or blue odorless solid, and cryolite (sodium hexafluoraluminate) is a colorless to dark, odorless solid. Fluorides are used as pesticides and rodenticides, as electrolytes in aluminum manufacture, as fluxes in the smelting of nickel, copper, gold, and silver, as catalysts for organic reactions, as wood preservatives, as fluoridation agents for drinking water, and to clean graphite, metals, windows, and glassware. Exposure to fluorides can also occur during the preparation of fertilizer from phosphate rock (Sittig 1985, p. 456; NIOSH/OSHA Occupational Health Guideline 1981, pp. 1, 3-4). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Fluoride compounds cause eye, skin, and respiratory tract irritation, and skeletal, gastrointestinal, circulatory, and nervous system effects in humans and animals. The oral LD50 in rats is 180 mg/kg for sodium fluoride (Lehman 1951-1952; Smyth et al. 1969, Muehlberger 1930, in Hayes 1982, p. 58). The LDso for sodium fluoroacetate in rats is 2.5 mg/kg (Kalmbach 1945, in Hayes 1982, p. 495). A 2 percent aqueous solution of sodium fluoride instilled into rabbit eyes caused corneal epithelial defects and necrotic areas in the conjunctiva (Grant 1986, p. 435). If fluoride is absorbed in sufficient amounts, the fluoride ion increases capillary permeability and causes a coagulation effect; this can lead to hemorrhagic gastroenteritis, congestion, and edema in various organs, including the brain (Booth and McDonald 1982, in HSDB 1986 "Cryolite"). The signs and symptoms of excess fluoride absorption include excitability, muscle tremors, weakness, urination, defecation, salivation, emesis, sudden collapse, clonic convulsions, coma, and death due to respiratory and cardiac failure (Booth and McDonald 1982, in HSDB 1986, "Cryolite"). Fluoroacetate acts on the central nervous system and heart to cause convulsions in dogs, cardiac effects in rabbits, and fits, severe depression, and death due to ventricular fibrillation or cardiac arrest in rhesus monkeys. All species experience a 0.5 to 2-hour delay between ingestion and onset of illness (Hayes 1982, p. 495). Rats fed sodium fluoride at levels of 7 to 14 ppm for 6 weeks developed dental fluorosis manifested as fine lines of impaired calcification; at a dietary level of 226 ppm, the incisors became chalky

and pitted. Dietary levels of 904 ppm caused marked weight loss and death within a few weeks (Smith and Leverton 1934, in Hayes 1982, p. 58). Chronic administration of fluoride in oral doses greater than 3.8 mg/kg caused changes in the teeth, liver, and kidneys of rats (IARC 1982, Vol. 27, p. 272). Intraperitoneal doses of stannous fluoride greater than 10 mg/kg of caused embryolethality and teratogenicity in mice (IARC 1982, Vol. 27, p. 272). A recent study in rats and rabbits (Eisenbrandt and Nitschke 1980, in Fund. Appl. Toxicol. 12(3):540-547) exposed by inhalation to various concentrations of sulfuryl fluoride for periods ranging from 2 weeks to 13 weeks reports the following findings. Nine of ten rats exposed to 600 ppm sulfuryl fluoride 6 hours/day, 5 days/ week died between the second and sixth exposures; at autopsy, extensive kidney damage was seen in all rats exposed at this level. Rabbits exposed to 600 ppm on the same regimen were hyperactive and one rabbit convulsed. All rabbits exposed either to 300 or 600 ppm for 2 weeks showed vacuolization and/or malacia of the cerebrum at autopsy. In a 13-week study in rats and rabbits, exposure to 30 ppm sulfuryl fluoride caused no effects. Exposure to 100 ppm for this period caused cerebral vacuolization and/or malacia and inflammation of the nasal tissues in some of the rabbits, and exposure to 300 ppm for 13 weeks caused mottling of the teeth, renal effects, pulmonary histiocytosis, nasal-tissue inflammation, and cerebral vacuolization in rats. Some rats exposed to 100 ppm had dental fluorosis. Various species of animals (mice, rats, cattle) have shown signs of impaired reproductive performance after ingesting large amounts (100 mg/l) of fluoride in their drinking water (IARC 1982, Vol. 27, p. 274; Maurer, Cheng, Boysen, Anderson 1990, in J. Nat. Cancer Institute 82(13):1118-1126). Rats fed 4, 10, or 25 mg/kg/day sodium fluoride for up to 99 weeks showed dose-related effects on the teeth, bones, and stomach; animals in the high-dose groups showed a 30 percent decline in weight gain. No increase in the incidence of preneoplastic or neoplastic lesions was seen at any site in rats of either sex. The International Agency for Research on Cancer has concluded that there is insufficient evidence to evaluate the carcinogenicity of sodium fluoride in animals (IARC 1982, Vol. 27, p. 292).

In humans, the lowest toxic dose of fluoride is reported to be 3 mg/kg; this dose produced pulmonary system, liver, and central nervous system effects (RTECS 1990, "Fluoride"). The acute effects associated with ingestion of a toxic dose of a soluble inorganic fluoride compound are vomiting, abdominal pain, and diarrhea (IARC 1982, Vol. 27, p. 276). Absorption of an estimated 0.2 to 27.5 g of fluoride after ingestion has resulted in convulsions; repeated ventricular fibrillation was observed after the ingestion of 120 g of sodium fluoride (IARC 1982, Vol. 27, p. 276). Death is usually due to respiratory paralysis (IARC 1982, Vol. 27, p. 276). In fatal cases of fluoride poisoning. autopsy reveals acute congestion of the abdominal viscera, swelling of the liver and kidneys, tubular necrosis, hemorrhage of the lungs, and dilation of the right chambers of the heart (IARC 1982, Vol. 27, p. 276). Workers exposed to fumes containing fluoride in concentrations above 10 mg/m3 fluoride reported experiencing irritation and nosebleeds (Williams 1942, in ACGIH 1986, p. 272). Eye and respiratory irritation and nausea occur in workers exposed to concentrations above 5 mg/ m3 (Elkins 1959, in ACGIH 1986, p. 272). Cryolite workers reported experiencing gastric, intestinal, circulatory, respiratory, and nervous system symptoms, as well as skin rashes and problems with their bones, joints, and muscles. The average workroom air concentrations in the cryolite plant ranged from 22 to 48 mg/m3 (which corresponds to a fluorine level of between 11 and 24 mg/m3) (Roholm 1937, in ACGIH 1986, p. 272). A recent study in Danish cryolite workers (Grandjean, Horder, and Thomassen 1990, in J. Occ. Med. 32(1):58-63) showed that exposure to cryolite dust at concentrations ranging from 0.16 to 21.2 mg/m3 for 4 days caused evidence of skeletal fluorosis. Workers in a Yugoslav aluminum processing plant had a significantly increased incidence of telangiectases (enlarged blood vessels); the authors attribute this to exposure to hydrogen fluoride and other fluorides (Balic and Kansky 1988, in Derma. Beruf. Umwelt 36(1):20-22). Repeated contact of the skin with fluoride dust results in dermatitis; several cryolite workers exposed to fluoride concentrations of 15 to 20 mg/ m³ developed an intermittent skin rash (AIHA Hygienic Guide Series 1978). Chronic exposure to fluoride can lead to effects on the teeth, bones, kidneys, and the reproductive and circulatory systems (IARC 1982, Vol. 27, p. 276). Aluminum workers, who are exposed to inorganic fluorides during the production process, showed evidence of bone and joint pathology believed to be attributable to the fluoride exposure (Czerwinski, Nowak, Dabrowska,

Klolarczyk, and Ksiezyk 1988, in Arch. Environ. Hlth. 43(5):340-343). A group of 2258 aluminum workers with an average exposure to fluoride of 17.8 years showed the following prevalence of joint and bone pathology on radiological examination: In those exposed up to 15 years, 135 cases; from 6 to 32 years, 1,463 cases, and in retired workers, 660 cases. A study of potroom workers exposed to fluorides during aluminum smelting showed that the majority had developed fluorosis after 10 years of exposure; after 15 years, moderate to severe osteosclerosis, causing limited mobility of the dorsal spine, developed in many workers (Kaltreider et al. 1972, in ACGIH 1986, pp. 272-273). A recent study (Tokar, Voroshinin, Zhovtak, and Shcherbakov 1989, in Gig. Sanit. 12:85-86) suggests an association between chronic occupational exposure to inorganic fluorides and adverse effects on the parathyroid gland and on the C-cells of the thyroid. The International Agency for Research on Cancer found no evidence of an association between fluoride ingestion and mortality from cancer in humans (IARC 1982, Vol. 27, p. 292).

Based on this evidence in humans and animals, OSHA preliminarily concludes that fluoride causes eye, skin, and respiratory irritation, and skeletal, gastrointestinal, circulatory, and nervous system effects in exposed individuals. OSHA therefore believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that extending the proposed limit of 2.5 mg/ m3 as an 8-hour TWA to agriculture is necessary to significantly reduce these risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for fluorides consistent across all regulated sectors. GLYCIDOL (2.3-EPOXY-1-PROPANOL) CAS: 556-52-5; Chemical Formula:

C3H6O2 H.S. No. 1189

Currently, OSHA has an 8-hour TWA limit for glycidol of 50 ppm in construction and maritime. There is no limit in agriculture. The ACGIH has a TLV°-TWA of 25 ppm for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour TWA limit of 25 ppm for glycidol in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry.

Glycidol is a colorless, combustible liquid. It is used as a stabilizer, a dyeleveling agent, and a demulsifier

(Hawley's 1987, p. 569; ACGIH 1986, p.

Glycidol causes eye, respiratory, and pulmonary irritation. Hine and associates (1956/Ex. 1-331) conducted a study of animal toxicity caused by glycidol exposure and reported that glycidol is irritating to the lungs: mice and rats both exhibited pneumonitis and emphysema as a result of vapor inhalation. The LCso in mice is 450 ppm for a 4-hour exposure; the 8-hour LCso in rats is 580 ppm (Hine, Kodama, Wellington et al. 1958/Ex. 1-331). A single dermal application was only mildly irritating (Draize score 4.5); however, repeated daily skin applications were severely irritating after 4 days. One drop of pure glycidol in the rabbit eye caused severe but reversible corneal injury (Hine, Kodama, Wellington et al. 1956/Ex.1-331). In rats. chronic exposures to 400 ppm (7 hours/ day for 50 days) did not cause systemic toxicity, but eye irritation and respiratory distress were observed after the first few exposures (Hine, Kodama, Wellington et al. 1956/Ex. 1-331). A study to determine glycidol's tumorigenic potential on the skin of mice showed negative results (Van Duuren. Langseth, Goldschmidt, and Orris 1967/ Ex. 1-1203).

OSHA is proposing to establish an 8hour TWA limit of 25 ppm for glycidol in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors from the significant risk of eye, respiratory, and pulmonary irritation potentially associated with exposure to this substance. The Agency believes that this limit will substantially reduce these significant risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. HEPTACHLOR

CAS: 78-44-8; Chemical Formula:

C10H5Cl2 H.S. No. 2088

In general industry, construction, and maritime, OSHA's current permissible exposure limit for heptachlor is 0.5 mg/ ms as an 8-hour TWA, with a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. There is no limit for heptachlor in agriculture. The ACGIH's current TLV*-TWA for this substance is 0.5 mg/m3 with a skin notation. NIOSH has no REL for heptachlor but concurs (Ex. 8-47, Table N3A) with the limit being proposed. The Agency is proposing to establish an 8-hour TWA PEL of 0.5 mg/ m³, and a skin notation, for heptachlor in agriculture. Promulgation of this limit

will make the PEL for this substance consistent across all OSHA-regulated

Heptachlor is a white to light tan waxy solid with a mild camphor-like odor. Heptachlor has been used as an insecticide, although its use has been restricted by the U.S. Environmental Protection Agency to subsurface soil treatment for termite control and the dipping of non-food plants (Hayes 1982, p. 233; ACGIH 1986, p. 296). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Heptachlor is a convulsant in humans and animals and a liver toxin and carcinogen in animals. In humans, exposure to heptachlor has also caused blood dyscrasias (EPA 1987 (ODW Health Advisory)). The oral LDso in rats is 40 mg/kg; in mice, it is 68 mg/kg (RTECS 1990). The dermal LDso in rabbits is 2000 mg/kg; rabbits dermally exposed convulsed before death (RTECS 1990). Rats given a single oral 90-mg/kg dose of heptachlor exhibited tremors and convulsions within 30 to 60 minutes of administration; liver necrosis was observed in these animals at autopsy (von Oettingen 1955, in Proctor, Hughes, and Fischman 1988, p. 268). Rats fed 7 to 12 mg/kg heptachlor per day for as long as 14 days showed evidence of severe liver damage and changes in liver function (Krampl 1971); these effects were also seen at a dietary level of 10 mg/kg for 5 to 7 days (Enan et al. 1982, both cites in ODW Health Advisory). In oral carcinogenicity bioassays involving heptachlor (contaminated with 20 percent chlordane), mice of both sexes developed liver carcinomas and female rats exhibited signs suggestive of a carcinogenic effect on the thyroid (IARC 1979, Vol. 20, p. 146). The International Agency for Research on Cancer has concluded that the evidence of heptachlor's carcinogenicity in animals is limited (IARC 1982, Suppl. 4, p. 81).

Humans exposed to chlordane that contained up to 20 percent heptachlor exhibited the same nervous system effects as those seen in heptachlorpoisoned animals: dyspnea, tremors, excessive salivation, irritability, and convulsions (EPA 1987, p. 5). These effects occurred regardless of the route of exposure: Dermal, ingestion, or inhalation. There are several reports of blood dyscrasias and aplastic anemia in workers exposed to heptachlor and chlordane (IARC 1982, Suppl. 4, p. 81). Epidemiological studies in chlordane and heptachlor applicators and of cyclodiene pesticide formulators have

yielded inconclusive results (IARC 1982, Suppl. 4, p. 81). Other studies suggest a relationship between heptachlor or chlordane exposure (alone or with other compounds) and blood dyscrasias, acute leukemia, and the development of neuroblastomas in children (IARC 1979,

Vol. 20, p. 146).

Based on this evidence in humans and animals, OSHA preliminarily concludes that heptachlor is a convulsant, liver toxin, and, based on effects seen in animals, a potential occupational carcinogen. OSHA therefore preliminarily concludes that, in the absence of a limit for heptachlor, workers in agriculture are at significant risk of experiencing these exposurerelated health effects. The Agency believes that the proposed TWA PEL of 0.5 mg/m3, with a skin notation, is necessary to substantially reduce these risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. HEXAFLUOROACETONE CAS: 684-16-2; Chemical Formula:

Currently, OSHA has no limit for hexafluoroacetone in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 0.1 ppm, with a skin notation, for this substance. OSHA is proposing a PEL of 0.1 ppm as an 8-hour TWA, with a skin notation, for this substance in construction, maritime, and agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the proposed limit, which was recently

industry.

C3F6O

H.S. No. 1198

Hexafluoroacetone is a colorless, nonflammable, highly reactive gas. It is used primarily in organic synthesis

established for this substance in general

(ACGIH 1986, p. 303).

Inhalation studies of hexafluoroacetone in animals have shown varied systemic toxicities, including injury to the liver, kidney, testes, thymus, and bone marrow. In rats and dogs exposed 6 hours/day, 5 days/ week for 13 weeks at concentrations of about 0.1, 1.0, or 12 ppm, no effects (other than increased lung weights in dogs) were observed in either species at 0.1 ppm. However, the 12-ppm exposures produced severe effects in both species, including marked but reversible testicular damage and slight hypoplasia of the spleen, thymus, and lymph nodes (E.I. du Pont de Nemours & Company, Inc. 1971, as cited in ACGIH 1986/Ex. 1-3, p. 303). Reversible kidney damage in rats and increased lung weights in dogs occurred during the 1.0-ppm exposures. An earlier 4-hour acute exposure of rats

demonstrated that 300 ppm was a lethal concentration (E.I. du Pont de Nemours & Co., Inc. 1971, as cited in ACGIH 1986/Ex. 1-3, p. 303).

In rats, 2-week dermal exposures of 65, 130, or 250 mg/kg resulted in numerous adverse effects, including testicular damage and corresponding changes in lipid metabolism (Kennedy, Henry, Chen, and Dashiell 1982/Ex. 1-1038). A dermal dose of 13 mg/kg produced no adverse effects in rats (Lee and Gillies 1984/Ex. 1-561). An injected dose of radiolabeled hexafluoroacetone was, for the most part, rapidly excreted in the urine in unmetabolized form; this material also did not accumulate in rat testes (Gillies and Rickard 1984/Ex. 1-322). Brittelli and co-workers (1979/Ex. 1-300) reported that hexafluoroacetone was fetotoxic in rats. Dermal application of 90 mg/kg/day to pregnant rats resulted in maternal toxicity. Fetal toxicity occurred at maternal doses of 25 mg/kg, and fetal size was reduced at maternal doses of 5 and 25 mg/kg; however, 1 mg/kg produced no fetal effect. Although soft-tissue damage and external abnormalities were observed, teratogenicity could not be demonstrated definitively (Brittelli, Culik, Dashiell, and Fayerweather 1979/ Ex. 1-300).

OSHA is proposing an 8-hour TWA PEL of 0.1 ppm TWA and a skin notation for hexafluoroacetone in construction. maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors from the significant risk of systemic injuries, reproductive effects, kidney damage, and fetotoxic effects, all of which constitute material health impairments that are associated with exposure to hexafluoroacetone at levels above the proposed PEL. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. HYDROGEN CYANIDE

CAS: 74–90–8; Chemical Formula: HCN H.S. No. 1207

The OSHA limit for hydrogen cyanide in construction and maritime is a 10-ppm 8-hour TWA, with a skin notation. There is no limit in agriculture. The ACGIH has a 10-ppm ceiling limit, also with a skin notation. NIOSH (1976e/Ex. 1–240) has recommended that workplace exposures to hydrogen cyanide not exceed 4.7 ppm (5mg/m³) as a 10-minute ceiling; however, NIOSH concurs (Ex. 8–47, Table N1) with the selection of the proposed PEL. OSHA is proposing a 15-minute STEL of 4.7 ppm, and a skin notation, for hydrogen cyanide in construction, maritime, and agriculture.

This is the limit recently established for this substance in general industry.

Hydrogen cyanide is a colorless gas at room temperature; it has a faint odor of bitter almonds. If contaminated with impurities or not adequately stabilized. hydrogen cyanide will polymerize spontaneously and violently. The commercially available product is usually 96 to 99 percent pure and contains a stabilizer. It is used in the manufacture of pesticides, rodenticides, chelates, dyes, and other substances including acrylonitrile, acrylates, adiponitrile, and cyanide salts (Hawley's 1987, p. 615). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

The ACGIH (1986/Ex. 1-3) has summarized the extensive body of human evidence on the adverse effects resulting from exposure to hydrogen cyanide. The Documentation notes that exposure to levels of 45 to 54 ppm hydrogen cyanide can be tolerated for 1 hour with no immediate or delayed effects, but that 18 to 36 ppm produces "slight" symptoms after several hours of exposure. The ACGIH also cites Grabois (1954/Ex. 1-1150), who reported that workers in apricot kernel processing plants experienced no ill effects when exposed to hydrogen cyanide at a concentration of approximately 10 ppm.

The NIOSH recommendation of 4.7 ppm as a 10-minute ceiling limit is based largely on an epidemiologic study by El Ghawabi et al. (1975/Ex. 1-632) that showed an increase in symptoms of headache, weakness, throat irritation, vomiting, dyspnea, lacrimation, colic, and nervousness among workers exposed to cyanide for an average of 7.5 vears. The 36 male workers who were studied were employed in three electroplating factories. Breathing zone samples (15 minutes in duration) were collected, and results ranged from 4.2 to 12.4 ppm. Cyanide levels at two of the three plants did not exceed 9.6 ppm. El Ghawabi et al. (1975/Ex. 1-632) also reported that two workers in one plant suffered from psychotic episodes; these conditions were reported to be similar to cases that occurred during the therapeutic use of thiocyanate. Mean values of urinary thiocyanate in the 36 workers correlated well with air concentrations of cyanide (El Ghawabi. Gaafar, El-Saharti et al. 1975/Ex. 1-632).

Symptoms resulting from chronic exposure to cyanide were also reported by Radojicic (1973, as cited in NIOSH 1976e/Ex. 1–240) among workers exposed to HCN levels between 5.4 and

12.3 ppm, and by Saia, DeRosa, and Galzigna (1970, as cited in NIOSH 1976e/Ex. 1–240). NIOSH (1976e/Ex. 1– 240) interpreted the significance of these studies as follows:

Colle (1972) * * * advanced the belief that these symptoms of headache, dyspnea, epigastric burning, vertigo, tinnitus, nausea, vomiting, tremor, and precordial pain represent a true clinical entity and that they are sufficiently documented and characteristic of chronic cyanide exposure to be grouped into a true syndrome. * * * Chaumont (1960) * * * also stated that

Chaumont (1960) * * * also stated that there is no clinical evidence to deny that cyanides can cause this type of occupational intoxication. He apparently found the debate on whether this intoxication is truly chronic or whether it involves repeated subacute symptoms to be semantic in nature and opted for the admission that chronic intoxication caused by HCN and the cyanide salts is a true occupational disease. * *

Thus, one might describe chronic cyanide poisoning as a slow deterioration of resistance, and, therefore, an intensified sensitivity, due to inadequate time between exposures for replacement of damaged tissues, enzyme systems and metabolic stores, the elimination of detoxication products, and the regeneration of homeostatic mechanisms (NIOSH 1976e/Ex. 1-240, pp. 90-91).

Based on this evidence, OSHA preliminarily concludes that a variety of symptoms are associated with exposure to hydrogen cyanide at concentrations below 10 ppm. OSHA is therefore proposing a 4.7-ppm 15-minute STEL, and a skin notation, for hydrogen cyanide in construction, maritime, and agriculture. The Agency believes that the short-term limit will protect workers in these sectors from the significant risk of headache, weakness, colic, and nervousness, which constitute material impairments of health; these effects have been observed in individuals exposed at the 10-ppm level over a full working shift. OSHA preliminarily concludes that this limit will substantially reduce these significant risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

HYDROGEN SELENIDE (as Se) CAS: 7783-07-5; Chemical Formula: H₂Se

H.S. No. 2093

In general industry, construction, and maritime, OSHA's current permissible exposure limit for hydrogen selenide (measured as selenium) is 0.05 ppm. There is no limit in agriculture. The ACGIH's TLV*-TWA for this substance is 0.05 ppm as an 8-hour TWA. NIOSH has no REL for this substance. The Agency is proposing to establish an 8-hour TWA PEL of 0.05 ppm for hydrogen

selenide in agriculture. Promulgation of this limit will make the PEL for hydrogen selenide consistent across all OSHAregulated sectors.

Hydrogen selenide is a colorless gas with a disagreeable odor like that of decaying horseradish. Hydrogen selenide is used to prepare metallic selenides and organoselenium compounds and in doping gas mixtures to prepare semiconductor materials (ACGIH 1986, p. 317; Braker and

Mossman 1980, p. 404). Hydrogen selenide is an irritant of the eyes, mucous membranes, and respiratory tract in humans and animals. The lowest lethal concentration in rats is 20 mg/ms for 1 hour (RTECS 1990). The LC50 in guinea pigs is 0.3 ppm (RTECS 1990). Signs of mucous membrane irritation, pulmonary edema, bronchitis, and bronchial pneumonia were seen in rats exposed to hydrogen selenide concentrations of 1 to 1.2 ppm (Buchan 1947, in Clayton and Clayton 1982, p. 2133). At a concentration of 10 ppm for 2 hours, guinea pigs exhibited signs of eye and nose irritation, and many of these animals died from pneumonitis (AIHA Hygienic Guide Series 1959, pp. 514-515).

The lowest toxic concentration of hydrogen selenide in humans is estimated to be 0.2 ppm (HSDB 1985). Exposure to a hydrogen selenide concentration of 1.5 ppm was judged intolerable by human subjects because of eye and nasal irritation. Exposure for a few minutes to a 0.3 ppmconcentration caused no irritation (Grant 1974, p. 560). Five workers exposed to hydrogen selenide at concentrations of less than 0.2 ppm for 1 month experienced nausea, vomiting, diarrhea, a metallic taste in the mouth. garlic odor of the breath, dizziness, lassitude, and fatigability; these symptoms gradually subsided during the months following exposure (Buchan 1974, in Proctor, Hughes, and Fischman 1988, p. 283). Other signs and symptoms caused by exposure to hydrogen selenide include runny nose and eyes, cough, sneeze, tightness of the chest, and pulmonary edema (Glover 1970, in ACGIH 1986, p. 317).

Based on this evidence in humans and animals, OSHA preliminarily concludes that hydrogen selenide's irritant effects pose a significant risk to workers in agriculture. The Agency believes that the proposed 8-hour TWA limit of 0.05 ppm is necessary to reduce the significant risk of material health impairment potentially associated with exposure to this substance. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

HYDROGENATED TERPHENYLS CAS: 61788-32-7; Chemical Formula: None H.S. No. 1210

Currently, OSHA does not regulate the hydrogenated terphenyls in construction, maritime, or agriculture. The ACGIH has a TLV®-TWA of 0.5 ppm (approximately 5 mg/m³) for these complex mixtures of ortho-, meta-, and para-terphenyls in various stages of hydrogenation. OSHA is proposing a PEL of 0.5 ppm as an 8-hour TWA for hydrogenated terphenyls in construction, maritime, and agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the proposed limit, which was the PEL recently established for these substances in general industry.

The hydrogenated terphenyls are mixtures of ortho-, meta-, and paraterphenyls in various stages of hydrogenation. Hydrogenated terphenyls are used as heat-transfer media and as plasticizers (ACGIH 1986, p. 311).

Acute exposure to the hydrogenated terphenyls poses a risk of potential lung, eye, and skin damage. Chronic exposure presents a risk of systemic toxicity involving injury to the liver, kidneys, and blood-forming organs, as well as possible metabolic disturbances and cancer (ACGIH 1986/Ex. 1–3, p. 311).

Early studies of unhydrogenated terphenyl isomers determined that the LD50 in rats is low, i.e., 1900 mg/kg for the ortho isomer, 2400 mg/kg for the meta isomer, and 10,000 mg/kg for the para isomer (Cornish, Bahor, and Ryan 1962/Ex. 1-410). Thirty-day oral administration of 500 mg/kg/day in the diet of rats indicated possible liver and kidney damage, which was suggested by increases in the liver- and kidney-tobody-weight ratios and decreases in the rate of weight gain (Cornish, Bahor, and Ryan 1962/Ex. 1-410). Other studies have demonstrated nephrotoxicity and liver damage in rats fed 33 mg/kg or more of unirradiated terphenyl isomers (Petkau and Hoogstraaten 1965/Ex. 1-432; Young, Petkau, and Hoogstraaten 1969/Ex. 1-459). Inhalation studies showed that bronchopneumonia is associated with exposure to 88 to 356 ppm of the ortho and meta isomers, but not to the para isomer at 103 ppm (Haley, Detrick, Komesu et al. 1959/Ex. 1-326). The work of Cornish, Bahor, and Ryan (1962/Ex. 1-410) showed that none of the isomers caused skin irritation in rabbits following a 24-hour dermal application. For terphenyls that are approximately 40-percent hydrogenated. the acute oral LD50 in rats is reported as 17,500 mg/kg; in mice, it is 12,500 mg/kg (Adamson and Weeks 1973/Ex. 1-295).

This study also demonstrated that an irradiated hydrogenated terphenyl mixture is three times more acutely toxic by ingestion than is a nonirradiated mixture. This finding was confirmed in 16-week chronic ingestion studies (Adamson, Bowden, and Wyatt 1969/Ex. 1–293); these authors found that 1200 mg/kg of an irradiated mixture was lethal to mice, while the same dose in nonirradiated form produced only an irreversible interstitial nephritis. In the same study, no effects were observed for either mixture at a dose level of 250

mg/kg. Eight-day inhalation studies in mice showed some pathologic changes in lung tissue after 500 mg/m3 (50 ppm) exposures to nonirradiated hydrogenated terphenyls; 8-week exposures at 2000 mg/m3 (200 ppm) resulted in the same lung damage, as well as in some proliferation of the smooth endoplastic reticulum in the liver (Adamson, Bowden, and Wyatt 1969/Ex. 1-293; Adamson and Weeks 1973/Ex. 1-295). Carcinogenesis in mice has been reported from 8-week skin exposures to the irradiated mixture (Henderson and Weeks 1973/Ex. 1-784). The significance of the changes observed by Adamson and Furlong (1974/Ex. 1-294) in the mouse lung after 8 weeks of inhalation exposure to the irradiated mixture is difficult to interpret in terms of the potential of the hydrogenated terphenyls to cause pulmonary cancer; particles were found to clear the lungs rapidly but to accumulate and clear more slowly in the intestine, kidney, and liver,

OSHA is proposing a 0.5-ppm 8-hour TWA PEL in construction, maritime, and agriculture for the complex mixtures of ortho-, meta-, and para-terphenyls (either irradiated or nonirradiated) in various stages of hydrogenation. The Agency preliminarily concludes that this limit will protect workers in these sectors from the significant risks of eye. skin, and lung damage and of systemic toxicity to the liver, kidneys, and bloodforming organs, all material health impairments that are potentially associated with exposure to these substances at levels above the proposed PEL. In addition, promulgation of this limit will make OSHA's PEL for these substances consistent across all regulated sectors.

2-ISOPROPOXYETHANOL CAS: 109-59-1; Chemical Formula: (CH₅)₂CHOCH₂CH₂OH H.S. No. 1223

OSHA has no limit for 2-isopropoxyethanol in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 25 ppm for this substance. NIOSH has no REL. OSHA is proposing a PEL of 25 ppm as an 8-hour TWA for this substance in construction, maritime, and agriculture. This is the limit recently established for 2-isopropoxyethanol in general industry.

2-Isopropoxyethanol is a mobile, combustible liquid. It is used as a solvent for resins, a dye for textiles, and as a component of lacquers and other coatings (ACGIH 1986, p. 335; Hawley's

1987, p. 660). 2-Isopropoxyethanol has been demonstrated to produce systemic toxicity in laboratory animals. In studies of rats, 15 6-hour exposures to 1000 ppm caused hemoglobinuria, anemia, and lung congestion, but no fatalities (Gage 1970/Ex. 1-318). At 300 ppm, Gage reported blood changes and lung congestion after 15 exposures. Exposure at the 100-ppm level produced no effect (Gage 1970/Ex. 1-318). Another study reported a significant increase in the osmotic fragility of erythrocytes in female rats after a 4-hour inhalation exposure to 62 ppm, but no effect was observed at 32 ppm (Carpenter, Pozzani, Weil et al. 1956/ Ex. 1-303). Studies of four species of experimental animals exposed at concentrations of 200, 50, or 25 ppm for 6 hours/day for 26 weeks reported hematologic changes only in rats: increased osmotic fragility of erythrocytes was marked at 200 ppm, slight at 50 ppm, and minimal at 25 ppm (Moffett, Linnett, and Blair 1976, as cited in ACGIH 1986/Ex. 1-3, p. 235)

In the prior rulemaking, NIOSH (Ex. 8–47) did not concur with OSHA's proposed limit of 25 ppm, noting that 25 ppm represented an effect level. Although "slight" increases in osmotic fragility were reported in animals subchronically exposed (Moffett, Linnett, and Blair 1976, as cited in ACGIH 1986/Ex. 1–3, p. 235), OSHA notes that a marked reaction did not occur until exposure was increased eightfold. Therefore, at this time, OSHA judges the 25-ppm PEL to be sufficiently protective.

OSHA is proposing to establish an 8-hour TWA PEL of 25 ppm for 2-isopropoxyethanol in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that this limit will substantially reduce the significant risk of hemolytic effects, which are material health impairments, that are associated with exposure to this substance. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

ISOPROPYL GLYCIDYL ETHER (IGE) CAS: 4016–14–2; Chemical Formula: C₆H₁₂O₂ H.S. No. 1227

OSHA's current limit for isopropyl glycidyl ether (IGE) in construction and maritime is 50 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH has an 8-hour TLV®-TWA of 50 ppm and a 15-minute TLV*-STEL of 75 ppm for IGE. NIOSH recommends a limit of 50 ppm as a 15-minute ceiling. OSHA is retaining the 8-hour TWA of 50 ppm and proposing to add a 15-minute STEL of 75 ppm for IGE in construction and maritime; the Agency is also proposing to extend both limits to agriculture. These are the limits recently established for this substance in general industry.

IGE is a colorless, volatile liquid. It is used as a stabilizer for chlorinated solvents and as a viscosity reducer for epoxy resins (Hawley's 1987, p. 662).

The 4-hour LCso for IGE in mice is 1500 ppm, and the 8-hour LC50 in rats is 1100 ppm (Hine, Kodama, Wellington et al. 1956/Ex. 1-331). The intragastric LDsos in mice and rats are 1.30 and 4.2 g/kg, respectively; in rabbits, the dermal LDso is 9.65 g/kg (Hine, Kodama, Wellington et al. 1956/Ex. 1-331). Fifty daily 7-hour exposures of rats to 400 ppm caused a reduced rate of weight gain, an increase in hemoglobin, a decrease in peritoneal fat, and, in some animals, emphysematous lungs and mottling of the liver (Hine, Kodama, Wellington et al. 1956/Ex. 1-331). Animals in this study also exhibited signs of ocular irritation and respiratory distress.

In humans, eye, nose, and upper respiratory tract irritation occurred in the technicians handling the animals in the Hine and co-workers' study (1956/Ex. 1-331); exposure levels were not specified. Dermatitis has also been reported in workers exposed to other glycidyl ethers during manufacture, and one such case involved IGE exposure (ACGIH 1986/Ex. 1-3, p. 340).

In construction and maritime, OSHA is retaining the 8-hour TWA of 50 ppm and proposing to add a 15-minute STEL of 75 ppm for IGE; the Agency is also proposing to extend both limits to agriculture. The Agency preliminarily concludes that both the TWA and STEL are necessary to reduce the risk to these workers of chronic organ effects, such as those demonstrated to occur in animals (Hine, Kodama, Wellington et al. 1956/Ex. 1-331), and the significant risk of eye, skin, and upper respiratory tract irritation associated with shortterm ICE exposures at the levels permitted in the absence of a STEL OSHA considers sensory irritation. dermatitis, and chronic organ effects to be material impairments of health. In addition, promulgation of these limits

will make OSHA's PELs for this substance consistent across all regulated sectors. LEAD, INORGANIC (as Pb) CAS: 7439-92-1; Chemical Formula: Pb H.S. No. 2098

The current OSHA limit for inorganic lead in the construction and maritime sectors is 0.2 mg/m^3 ($200 \, \mu\text{g/m}^3$), and in general industry it is $50 \, \mu\text{g/m}^3$. There is no PEL for lead in agriculture. The ACGIH has a TLV*-TWA of $0.15 \, \text{mg/m}^3$ for lead. NIOSH has a REL of $<100 \, \mu\text{g/m}^3$ as a 10-hour TWA. OSHA is proposing an 8-hour TWA PEL of $50 \, \mu\text{g/m}^3$ for lead in the construction, maritime, and agriculture sectors. This is the limit established by OSHA in 1978 for lead in general industry workplaces (see 29 CFR 1910.1025).

Lead is a ductile, soft, heavy, gray, metallic element. It is used in batteries, radiation shielding, ammunition, solder, and in cable coverings. It has many other industrial uses (Hawley's 1987, p.

687).

Lead has profound and adverse effects on the health of exposed workers. Inhalation, the most important source of lead intake, and ingestion result in damage to the nervous, urinary, and reproductive systems and additionally inhibit synthesis of the heme molecule, which is responsible for oxygen transport in living systems. The adverse health effects associated with exposure to lead range from acute and perhaps reversible effects such as inhibition of enzyme activity, reduction in motor nerve conduction velocity, behavioral changes, and mild central nervous system (CNS) symptoms, to chronic disease and death.

The signs and symptoms of severe lead intoxication associated with blood lead levels of 80 µg/100 g and above are well documented. In recent years, however, there have been numerous research findings indicating that adverse health effects are associated with lead concentrations previously thought to be inconsequential. The following subsections will address the health effects of low level lead exposure in each system: heme synthesis inhibition and damage to the nervous, urinary, and reproductive systems. Prior to this, however, the air to blood lead relationship will be addressed

Air to blood relationship. OSHA believes that a relationship between air lead levels and population-average blood lead levels unquestionably exists. In order to accurately predict the effects on blood lead levels that are produced over time by changes in air lead levels, it was necessary to construct a model that takes into account the important

factors that affect blood lead levels. The adaptation of the physiological model originally developed by S.R. Bernard by the Center for Policy Alternatives (CPA) (Doc. H-004, Ex. 439) combines experimentally observed properties of mammalian lead transport and metabolism, including considerations of the dynamics of blood lead response to long-term exposure with observed physical properties of airborne particulates encountered in the workplace to produce a complete and accurate picture of the response of blood lead levels to particulate lead exposure. The Bernard model is an example of one of the most common types of models used to describe the transport and metabolism of drugs or foreign substances in the body; models of this type are known as multicompartment mammalian models. OSHA believes that the CPA's application of the Bernard model accurately predicts the effects on blood lead levels that are produced over time by changes in air lead levels.

Based on calculations using the CPA adaptation of the Bernard model, OSHA predicts that, assuming compliance with the proposed PEL of 50 µg/m3, 0.5 percent of all blood lead levels (PbB) collected from exposed workers will exceed 60 µg/100 g; 5.5 percent of workers will have a PbB between 50 and 60 µg/100 g; 23.3 percent will have levels between 40 and 50 µg/100 g; and overall, 29.3 percent will have PbBs above 40 μg/100 g at any one time. These blood lead levels would represent a substantial improvement in the blood lead levels for workers in these sectors under current conditions. The current blood lead level distribution, assuming compliance with a 200 µg PEL, is approximately (1) 22.4 percent of workers with PbBs greater than 60 µg/ 100 g; (2) 32.6 percent with PbBs between 50 and 60 µg/100 g; (3) 28.7 percent of workers with PbBs between 40 and 50 μg/100 g; and (4) overall, 83.3 percent with PbBs above 40 µg/100 g.

Heme Synthesis Inhibition. The earliest demonstrated effect of lead involves its ability to inhibit the formation of heme. Scientific evidence has established that lead inhibits at least two enzymes of the heme synthesis pathway at very low blood lead (PbB) levels. Inhibition of delta aminolevulinic acid dehydrogenase (ALAD), an enzyme responsible for the synthesis of a precursor to heme, is observed at PbB levels below 20 µg/100 g (Hernberg et al., Doc. H-004, Ex. 6-20). At a PbB level of 40 µg/100 g, more than 20 percent of the population would have a 70 percent inhibition of ALAD. Another product of impairment that builds up and that indicates inhibition of another enzyme,

ferrochelatase, also occurs at low PbB levels. At a PbB level of $50~\mu g/100~g$, a larger proportion of the population would suffer a more extreme version of these effects. At a PbB level of $50~\mu g/100~g$, 70 percent of the population would have a 70 percent inhibition of ALAD and 80 percent of men and 100 percent of women would have increased free erythrocyte protoporphyrin, which is the product of inhibition of ferrochelatase (Zeilhuis, Doc. H–004, Ex. 294E).

The depression of heme synthesis in all cells of the body is a potentially ferreaching effect, and the prevention of enzyme effects is thus the key to the prevention of more serious clinical effects of lead toxicity, which become more obvious as the exposure continues. These measurable effects are a direct result of lead exposure and are considered by the Agency to indicate the occurrence of disruptions of a fundamental and vital subcellular

process, heme synthesis.

OSHA believes that the toxicological evidence indicates a progression of health effects caused by lead exposure that starts with the inhibition of enzymes, continues through effects demonstrating a measurable disruption of subcellular processes (such as the buildup of the products of impaired heme synthesis), and eventually develops into overt signs and symptoms of lead poisoning that are manifested as disorders of the nervous, renal, and blood-forming systems. Given this understanding of the progressive stages of lead toxicity, OSHA has preliminarily concluded that enzyme effects indicative of the disruption of heme synthesis are early stages of a disease process that eventually results in the clinical symptoms of lead poisoning. Whether or not the effects have proceeded to the later stages of clinical disease, disruption of these processes over a working lifetime must be considered a material impairment of health. As was previously discussed, at a PbB level of 40 µg/100 g and above, a significant proportion of the population would manifest extensive inhibition of ALAD as well as elevations of protoporphyrin levels. The Agency believes that PbB levels should ideally be kept below 40 µg/100 g to minimize these effects.

Neurological effects. Lead exposure may adversely affect both the central and peripheral nervous systems. In particular, Lilis et al. (Doc. H–004, Ex. 24–10) have demonstrated central nervous system symptoms in 56 percent of workers with blood lead levels below 80 μ g/100 ml. The mean blood level was approximately 60 μ g/100 ml. This same

study reported symptoms of muscle and joint pain and/or soreness in 39 percent of the workers, many of whom had been exposed for less than a year. The authors cautioned that blood lead levels should not be allowed to exceed 60 µg/ 100 ml and should be maintained around 40 µg/100 ml. OSHA is of the opinion that the earliest stages of lead-induced central nervous system disease first manifest themselves in the form of behavioral disorders and CNS symptoms. OSHA preliminarily concludes that a blood lead level of 40 μg/100 g must be considered a threshold level for behavioral changes and mild CNS symptoms in adults and that, to protect against long-term neurological effects, blood lead levels should never exceed 50 µg/100 g.

The earliest sign of neurological disease of the peripheral nerves is a slowing of motor nerve conduction velocity (NCV). Slowing of NCV is seen in workers with no obvious clinical signs of lead poisoning. OSHA believes that prevention of this stage is necessary to prevent further development of the disease and its associated forms, which are likely to be irreversible. The work of Catton et al. (Doc. H-004, Ex. 5-15, Ref. 2), Feldman (Doc. H-004, Ex. 24-19, pp. 15), Behse (Doc. H-004, Ex. 24-19, pp. 15), Gerard (Doc. H-004, Ex. 24-19, pp. 15), Guardriglia (Doc. H-004, Ex. 51-B), Araki and Honma [Doc. H-004, Ex. 51-B), Repko et al. (Doc. H-004, Ex. 5-14), and Seppalainen et al. (Doc. H-004, Ex.5-12) all demonstrates statistically significant loss of motor NCV in leadexposed workers. Seppalainen and his co-workers were able to determine a dose-response relationship between blood lead levels and the slowing of NCV. It is apparent that slowing occurs in workers whose PbB levels are 50 µg/ 100 g and above. Therefore, a necessary goal of a standard for occupational lead exposure must be to ensure that blood lead levels are maintained below 50 µg/

Renal system. The research of Wedeen and co-workers, the Health Hazard Evaluation done by NIOSH at Eagle Picher Industries, Inc. (Doc. H-004, Ex. 38C), and the research in secondary smelters done by Lilis, Fishbein, et al. (Doc. H-004, Ex. 23) all demonstrate that lead exposure is a key etiologic agent in the development of kidney disease among occupationally exposed workers. Wedeen et al. (Doc. H-004, Tr. 1765-1766) found that very few workers in a group of lead workers with kidney disease had blood lead levels over 60 µg/100 g. The authors concluded, therefore, that 40 µg/100 g was the

upper acceptable PbB limit (Doc. H–004, Tr. 1771). OSHA believes that maintenance of PbB levels at or below $40~\mu g/100~g$ will reduce the overall lead dose to the worker, decrease the body burden of lead, and prevent sufficient buildup of lead in the kidney to produce renal damage.

Reproductive effects. Exposure to lead has been associated with adverse reproductive effects in both males and females. In male workers exposed to lead, there is evidence of decreased sexual drive, impotence, decreased ability to produce healthy sperm, and sterility. Lancranjan and co-workers (Doc. H-004, Tr. 577) have demonstrated that the reproductive ability of men occupationally exposed to lead is altered. These authors reported a significant increase in malformed sperm (teratospermia) among workers with mean PbB levels of 74.5 µg/100 ml or 52.8 µg/100 ml. A decreased number of sperm (hypospermia) and decreased sperm motility (athenospermia) were observed not only in the preceding groups but also in those with only slightly increased absorption, i.e., in those with a mean PbB level of 41 µg/ 100 ml. The authors concluded that these alterations were produced by a direct toxic effect on the male gonads, and that a dose response relationship exists with respect to teratospermia. In OSHA's view, altered spermatogenesis, which reflects impaired reproductive capacity in the male, is a material impairment of health.

Lead may cause genetic damage in the egg or sperm cells before conception, and this damage may be passed on to the developing fetus. The record (Doc. H-004) indicates that genetic damage from lead may occur prior to conception in either males or females. The result of genetic damage could be failure to implant, miscarriage, stillbirth, or birth defects.

There is conclusive evidence that lead passes through the placental barrier. The lead levels in the mother's blood are comparable to concentrations of lead in the umbilical cord blood at birth. The record (Doc. H-004) indicates that, as a result, the exposure of women to lead is associated with abnormal ovarian cycles, premature birth, menstrual disorders, sterility, miscarriage, and stillbirth. Maternal lead poisoning may also result in a short gestational period, low birth weight, postnatal growth retardation, impeded neurobehavioral development, and infant mortality.

There is little direct data on damage to the fetus from exposure to lead but there are extensive studies that demonstrate neurobehavioral effects at blood leads of about 30 µg/100 ml and above in children. OSHA believes that the fetus and newborn are likely to be at least as susceptible to neurological damage as older children and therefore that data on children are also relevant to the fetus. Exposure to lead would be expected to adversely affect heme biosynthesis and the nervous system earliest and most profoundly in the fetus. Damage to the fetus reflects impairment of the reproductive capacity of the parent and is considered by OSHA to constitute a material impairment of functional capacity within the meaning of the Act.

In children, behavioral disturbances such as hyperactivity have been associated with blood lead levels of between 25 and 55 µg/100 ml. Beattie (1975, Doc. H-004, Ex. 6-6) demonstrated an increased probability of mental retardation in children exposed to lead via maternal ingestion of lead in water. Elevated blood lead levels were found in the retarded children when their blood leads were compared with those of children in the control group. There appeared to be a significant relationship between blood lead concentration and mental retardation. The mean blood lead level for the retarded children was 25.5 µg/100 ml.

Motor nerve conduction velocity (NCV) decrements indicating early peripheral neuropathy have also been reported in children. Early studies showed NCV decrements in children whose blood lead levels were 40 µg/100 g and above.

Given the available data, OSHA preliminarily concludes that, to protect the fetus and newborn from the effects of lead on the nervous system, airborne lead levels in workplaces where their maternal parents are employed must be kept below 50 μg/m³. OSHA believes that this evidence overwhelmingly indicates that the lead exposure levels for workers who may wish to have children should be maintained below 50 µg/m3 in order to minimize adverse effects from lead on the worker's reproductive abilities. To minimize the risk of genetic damage, menstrual disorders, interference with sexual function, lowered fertility, difficulties in conception, damage to the fetus during pregnancy, miscarriage, stillbirth, toxic effects on the newborn, and problems with the healthy development of the newborn or developing child, lead exposure levels should be kept below 50 μg/m³ for both male and female workers who are exposed to lead and who may wish to have children. Although there is no evidence for a "no effect" level for lead, OSHA believes

that the risk of reproductive effects would be minimized at this concentration.

OSHA believes that this evidence preliminarily shows that workers exposed to lead suffer material impairments of health at blood lead levels far below those previously considered hazardous. Inhibition of the heme biosynthesis pathway, early stages of peripheral and central nervous system disease, reduced renal function, and adverse reproductive effects are all evidence of adverse health effects from occupational exposure to lead in workers whose blood lead levels are at 40 μg/100 g and above. OSHA has preliminarily concluded that blood lead levels should be maintained at or below 40 µg/100 g and even lower for workers who wish to have children. Therefore, OSHA is proposing an 8-hour TWA PEL. for lead of 50 μg/m3 to protect workers in the construction, maritime, and agriculture sectors from the significant risk of these adverse health effects. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. METHYL HYDRAZINE CAS: 60-34-4; Chemical Formula:

OSHA's current permissible exposure limit for methyl hydrazine in general industry, construction, and maritime workplaces is 0.2 ppm as a ceiling; this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. OSHA has no PEL for methyl hydrazine in agriculture. The ACGIH's current TLV® for this substance is 0.2 ppm as a ceiling, with a skin notation. The ACGIH considers this substance a potential human carcinogen and assigns it an A2 classification, and NIOSH also designates methyl hydrazine a potential occupational carcinogen; the REL for methyl hydrazine of 0.04 ppm as a 2hour ceiling. OSHA is proposing a PEL of 0.2 ppm as a ceiling, with a skin notation, for methyl hydrazine in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors

CH₃NHNH₂

H.S. No. 2112

Methyl hydrazine, also called monomethyl hydrazine, is a clear, colorless liquid with an ammonia-like odor. This substance is used in missile propellants and as a solvent and chemical intermediate (ACGIH 1986, p. 398(89)).

Methyl hydrazine causes central nervous system depression, liver damage, and blood dyscrasias in humans and animals. This substance is

a carcinogen and teratogen in experimental animals and is also a suspected human carcinogen (ACGIH 1986, p. 398(89); Proctor, Hughes, and Fischman 1988, p. 334). The oral LD50s in rats, mice, and hamsters are 32 mg/kg, 29 mg/kg, and 22 mg/kg, respectively (RTECS 1990). The LCso for rats is 34 ppm for 4 hours, and for monkeys the LCso is 82 ppm for 1 hour; before death, monkeys showed signs of conjunctival irritation and nausea and then convulsed (RTECS 1990). The dermal LD₅₀ in rabbits is 95 mg/kg (RTECS 1990). Acute toxicity in animals poisoned by methyl hydrazine is characterized by convulsions, neurological effects, hypoglycemia, anemia, vomiting, and irritation of the nose and eyes (NIOSH Criteria Document 1978). Undiluted methyl hydrazine that has been applied to the skin of dogs at doses ranging from 14.7 to 264.5 mg/kg was detected in the bloodstream of these animals within 30 seconds (Smith and Clark 1969, in ACGIH 1986, p. 398(89)]. Methyl hydrazine caused corneal edema in dogs after it was applied to their skin and carried to the eyes by the bloodstream (Takahashi and Dasher 1969, in ACGIH 1986, p. 398(89)). Dogs exposed to a 21ppm concentration of dimethyl hydrazine for 4 hours convulsed and died; autopsy revealed pulmonary hemorrhage and edema in these animals. At a 15-ppm concentration, however, the dogs convulsed but survived (Jacobson et al. 1970, in Proctor, Hughes, and Fischman 1988, p. 334). Hemolysis and Heinz bodies in the erythrocytes were seen in monkeys exposed to a 5-ppm concentration of methyl hydrazine for 6 hours/day for 6 months; no effects were observed at lower doses (MacEwen and Haun 1971; Kroe 1971, in ACGIH 1986, p. 398(89)]. Pregnant female rats receiving intraperitoneal injections of 2.5, 5.0, or 10 mg/kg of methyl hydrazine on days 6 through 15 of gestation showed a reduction in body weight; embryotoxic effects and an equivocal increase in eye abnormalities were observed in the offspring (Keller et al. 1984, in ACGIH 1986, p. 398(89)). The offspring of rats given intraperitoneal doses of 50 mg/kg methyl hydrazine during days 6 through 15 of pregnancy had an increased incidence of developmental abnormalities of the eyes and ears (RTECS 1990). Mice developed lung tumors and hamsters developed malignant histiocytomas of the liver and cecal tumors when methyl hydrazine was administered to these animals in the drinking water at concentrations of 0.01 percent (Toth 1972, Toth and Shimizu 1972, in ACGIH 1986, p.

398.1(89)). The potential carcinogenicity of methyl hydrazine vapor has also been investigated in several species; studies involving exposures to methyl hydrazine at concentrations ranging from 0.02 ppm to 5 ppm were conducted for 6 hours/ day, 5 days/week for 1 year (Kinkeah et al. 1985, in ACGIH 1986, p. 398.1(89)). Rats exposed to methyl hydrazine concentrations of 0.02 ppm and higher had a decrease in their rate of growth. and mice exposed to a 2-ppm concentration developed lung tumors. nasal adenomas, nasal polyps, nasal osteomas, hemangiomas, and liver adenomas and carcinomas (Kinkeah et al. 1985, in ACGIH 1986, p. 398.1(89)). Dogs exposed on this regimen to concentrations of 0.2 ppm and above showed a reversible decrease in red blood cell count, hematocrit, and hemoglobin; at 2 ppm, they exhibited a reversible increase in methemoglobin and signs of liver pathology (Kinkeah et al. 1985, in ACGIH 1986, p. 398(89)]. Hamsters in these studies showed lower body weights and an increased incidence of nasal adenomas when exposed to a 5-ppm concentration of methyl hydrazine (Kinkeah 1985, in ACGIH 1986, p. 398.1(89)).

Methyl hydrazine is the strongest convulsant of the methyl-substituted hydrazines (Clayton and Clayton 1981, p. 2292). In high doses, this substance also can cause extensive kidney damage. Liver changes are primarily of the fatty degeneration type and seldom progress to necrosis (Parmeggiani 1983, p. 1069). Methyl hydrazine poisoning can result in tremors, increased central nervous system excitability at high doses, and convulsions that can be fatal (HSDB 1985). Methyl hydrazine causes oxidative damage to human erythrocytes in vitro; effects include Heinz body formation and methemoglobin production (NIOSH Criteria Document 1978). Human volunteers exposed to a 90-ppm concentration of methyl hydrazine for 10 minutes developed eye redness and a tickling sensation in the nose; Heinz body formation in 3 to 5 percent of the volunteers' erythrocytes became apparent on the seventh day after exposure (NIOSH Criteria Document

Based on this evidence, OSHA preliminarily concludes that, in the absence of a permissible exposure limit, workers in agriculture are at significant risk of experiencing the serious exposure-related effects associated with methyl hydrazine. The Agency believes that establishing a 0.2 ppm ceiling limit, with a skin notation, is necessary to substantially reduce these risks of

material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. 4.4'-METHYLENE BIS(2-

CHLOROANILINE) CAS: 101-14-4; Chemical Formula: CH2(C6H4CINH2)2 H.S. No. 1273

OSHA has no limit in construction, maritime, or agriculture for 4.4'methylene bis(2-chloroaniline), or MBOCA, although in 1974, OSHA did issue a standard for MBOCA as part of the Agency's "14 Carcinogens" rulemaking; however, the reviewing court set the MBOCA standard aside on procedural grounds. The ACGIH has a TLV*-TWA of 0.02 ppm (0.22 mg/m3), with a skin notation, and classifies MBOCA as a suspected human carcinogen (A2). NIOSH recommends a TWA limit of 3 µg/m3 for MBOCA, which NIOSH considers a potential occupational carcinogen. OSHA is proposing an 8-hour TWA PEL of 0.02 ppm (0.22 mg/m3) TWA for MBOCA, with a skin notation, in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry

MBOCA is a tan-colored solid. It is used as a curing agent for polyurethanes and epoxy resins (Hawley's 1987, p. 767).

MBOCA is highly toxic, causing cyanosis, kidney irritation, methemoglobinemia, and cancer. It is similar in many of its effects to the other aromatic amines (Hosein and van Roosmalen 1978/Ex. 1-1054; Mastromatteo 1965/Ex. 1-146). Steinhoff and Grundmann (1969/Ex. 1-762) demonstrated that feeding MBOCA at unspecified levels to rats on a proteindeficient diet caused a high incidence of liver cancer. Russfield, Homburger, Boger and associates (1975/Ex. 1-929) reported liver and lung tumors in rats fed MBOCA while on a standard diet. Dogs fed MBOCA at a dose of 100 mg/ day, 5 days/week showed no hepatic cancer, but malignant nodules in the bladder occurred in a dog fed MBOCA for 9 years (Stula et al. 1977, as cited in ACGIH 1986/Ex. 1-3, p. 392.4).

In industry, reversible hematuria has been reported among MBOCA-exposed workers, but data on the associated exposure levels are lacking (Mastromatteo 1965/Ex. 1-146). An early study of workers exposed for as long as 18 years to MBOCA showed no adverse effects, although the substance and its metabolites were detected in the urine of these subjects (Linch, O'Connor, Barnes et al. 1971/Ex. 1-791). Hosein and van Roosmalen (1978/ Ex. 1-1054)

reported an industrial accident in which molten MBOCA was splashed in a worker's face; urinary levels of 3.6 mg/L MBOCA, as well as protein, were detected in the urine, and the subject experienced nausea. However, this worker recovered quickly.

A recent NIOSH retrospective study involving 370 workers employed in a MBOCA-manufacturing plant evaluated the carcinogenicity of this substance, which is structurally similar to benzidine. This study found two cases of bladder cancer in very young workers (less than 30 years of age), both of whom were nonsmokers.

In the prior rulemaking, the Polyurethane Manufacturers Association (PMA) expressed its support for establishing a 0.02-ppm TWA PEL for MBOCA, stating that the proposal "will significantly assist in assuring that any exposure to the chemical is appropriately controlled while imposing a regulation which can be feasibly complied with by employers" (Ex. 3-683, p. 4). The PMA also supported the addition of a skin notation for MBOCA, identifying dermal contact as a "principal potential route for employee exposure" (Ex. 3-683, p. 7).

Other commenters in the earlier rulemaking (Ex. 8-47, 194) urged OSHA to undertake a separate 6(b) rulemaking for MBOCA. OSHA shares these commenters' concerns about MBOCA's toxicity; however, the primary goal of this rulemaking is to achieve consistency in OSHA's PELs across sectors. In the first PEL update, OSHA will evaluate the toxicologic evidence on MBOCA to determine whether the evidence warrants a further reduction in the exposure limit.

Based on this evidence in humans and animals, OSHA is proposing to establish an 8-hour TWA limit of 0.02 ppm, with a skin notation, for MBOCA in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risks of cyanosis, methemoglobinemia, kidney irritation, and bladder cancer, all material health impairments potentially associated with exposure to this substance. A skin notation is being proposed to protect workers against the percutaneous absorption and systemic toxicity demonstrated to occur with this substance in industrial accidents. Promulgation of the proposed limit of 0.02 ppm will also make OSHA's PEL for this substance consistent across all regulated sectors.

MOLYBDENUM, SOLUBLE COMPOUNDS (as Mo) CAS: 7439-98-7; Chemical Formula: Mo H.S. No. 2111

OSHA's current permissible exposure limit for the soluble molybdenum compounds in construction and maritime is 5 mg/m3 (measured as molybdenum) as an 8-hour TWA. There is no limit in agriculture. The ACGIH has an 8-hour TLV*-TWA limit of 5 mg/ m3 for these substances. There is no NIOSH REL. OSHA is proposing an 8hour TWA of 5 mg/m3 for the soluble compounds of molybdenum in agriculture. Promulgation of this limit will make the PEL for these substances. consistent across all OSHA-regulated

The soluble compounds of molybdenum include molybdenum trioxide, ammonium molybdate. ammonium paramolybdate, and calcium molybdate, all of which are yellow to white, odorless solids. These substances are used as electrodes, chemical reagents, intermediates in the manufacture of corrosion inhibitors, coloring agents, agricultural chemicals. pigments for paints, lacquers, dyes, and catalysts, and in electroplating and enameling (NIOSH/OSHA Occupational Health Guideline 1981, p. 4; Hawley's 1987, pp. 68, 205-206, 795, and 1065-

Molybdenum's soluble compounds cause eye, nose, and respiratory irritation, central nervous system effects, anemia, and liver and kidney damage in humans and animals. The oral LDso for molvbdenum trioxide in rats is 125 mg/kg; the lowest lethal concentration in the same species is 1? g/m3 for 1 hour (RTECS 1990). Ammonium molybdate has an oral LD₅₀ of 333 mg/kg in rats (RTECS 1990). There is a subcutaneous LD₅₀ of 570 mg/ kg for sodium molybdate in mice (RTECS 1990). Guinea pigs and rats fed 1200 to 6000 mg/kg doses of molybdenum trioxide, calcium molybdate, or ammonium molybdate died: there were fewer fatalities among animals fed 120 to 600 mg/kg doses (ACGIH 1986, p. 415). In rats, the inhalation of estimated 100 mg/kg/day doses of molybdenum trioxide by inhalation irritated the eyes and mucous membranes and was lethal (Klaassen, Amdur, and Doull 1986, p. 615). Molybdenum trioxide was extremely irritating to guinea pigs after repeated 1hour exposures to 250 mg/m³; symptoms included appetite and weight loss, diarrhea, muscular incoordination, and hair loss. Twenty-six of the 51 animals exposed died after the tenth exposure (Fairhall, Dunn, Sharpless, and Pritchard 1951, in Clayton and Clayton 1981, p. 1813). Cattle, rabbits, and chicks fed high levels (dose not specified) of

molybdenum displayed deformities of the joints of the extremities (Ferguson et al. 1943; Maltoni 1973, in Clayton and Clayton 1981, p. 1814). In rats and guinea pigs, ammonium molybdate at oral doses of 1.2 g/kg caused anorexia, colic, trembling, incoordination, and dyspnea; rabbits showed signs of anemia and deformity of the forelegs (Browning 1969, in Proctor, Hughes, and Fischman 1978, p. 359). Repeated oral doses (amount unspecified) induced fatty degeneration of the liver and kidney in rats (Klaassen, Amdur, and Doull 1986, p. 615).

In humans, the lowest toxic concentration of molybdenum trioxide is estimated to be 6 mg/m3 over 4 years; coughing and signs of focal fibrosis were observed in the individual involved in this incident (RTECS 1990). Exposure to molybdenum trioxide causes irritation of the eyes, nose, and throat (HSDB 1990). Anemia, a characteristic symptom of molybdenum intoxication, is manifested by low hemoglobin concentrations and reduced red-cell counts (HSDB 1989). In workers at a Soviet molybdenum-copper plant, chronic exposure led to liver dysfunction and hyperbilirubinemia (Avakyau 1968, in Clayton and Clayton 1981, p. 1814). Gout, with signs and symptoms that included joint pain, articular deformities, erythema, and edema of the joints, has been seen among factory workers and inhabitants of the molybdenum-rich areas of Armenia (Kovalskii 1961; Akopyan 1966, in Clayton and Clayton 1981, p. 1818). Three of 19 workers exposed to molybdenum and molybdenum trioxide at concentrations ranging from 1 to 19 mg/m3 for 4 to 7 years showed evidence of pneumoconiosis (HSDB 1990).

Based on this evidence, OSHA preliminarily concludes that exposure to soluble molybdenum compounds causes eye, nose, and respiratory tract irritation, anemia, and joint pain. OSHA therefore believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that the proposed PEL of 5 mg/ m3 as an 8-hour TWA limit for soluble molybdenum compounds in agriculture is necessary to significantly reduce the risks of these material health impairments. Promulgation of this limit will also make the PEL for these substances consistent across all OSHAregulated sectors.

NICKEL, METAL AND INSOLUBLE COMPOUNDS (as Ni) CAS: 7440-02-0; Chemical Formula:

Varies with compound
H.S. No. 2114

In general industry, construction, and maritime, OSHA's current PEL for nickel and its insoluble compounds (measured as nickel) is 1 mg/m3 as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV®-TWA of 1 mg/m3; NIOSH has a REL of 0.015 mg/m3 (measured as nickel) as a 10-hour TWA; this limit is based on nickel's carcinogenicity. OSHA is proposing an 8-hour TWA PEL of 1 mg/m3 in the agricultural sector for nickel and its insoluble compounds (measured as nickel). This action will make the PEL for these substances consistent across all regulated sectors.

Nickel is a hard, silver-white, magnetic metal. The principal insoluble compounds of nickel in industrial use are nickel oxides, nickel-containing alloys, nickel hydroxide, nickel sulfide, nickel carbonate, and nickel phosphate (ACGIH 1986, p. 422; AIHA 1978). Metallic nickel is used in the manufacture of stainless steel, various other alloys, and in electroplating.

Contact of the skin with metallic nickel and some of its compounds causes dermal sensitization, and exposure to nickel subsulfides or nickel oxide has been determined by the International Agency for Research on Cancer to cause cancer in humans (IARC 1982, Suppl. 4, pp. 167-170). Nickel is also carcinogenic in experimental animals. The lowest lethal dose of nickel in rats is 5 g/kg (RTECS 1990). Rats exposed to a 1 mg/m3 concentration of nickel sulfide for 14 months developed a significant excess of lung cancer (Hueper 1958, in AMA Arch. Pathol. 65:600). Exposing hamsters to nickel oxide at a concentration of 53 mg/m3 caused pneumoconiosis described by the authors of the study as "massive" (Wehner, Busch, Olson, and Craig 1975, in Am. Ind. Hyg. Assoc. J 36:801). Rats and mice were exposed to nickel subsulfide 6 hours/day for 12 days at concentrations ranging from 0.7 to 13.5 mg/m3 (measured as nickel); mice and rats developed degeneration of the epithelium of the respiratory tract at the 0.9 mg/ms Ni exposure, and the rats additionally developed pulmonary inflammation (National Academy of Sciences 1975, in ACGIH 1986, p. 422(89)). Nickel oxide exposure (at a nickel concentration of 0.112 mg/m3) for 12 hours/day, 6 days/week for 2 weeks caused increases in alveolar macrophages and thickened alveolar walls (Bingham, Barkley, Zerwas, et al. 1972, in Arch. Environ. Hlth. 25:406). Nickel subsulfide exposure at a concentration of 0.97 mg/ms nickel for 78 weeks caused lung cancers in 14 of 208 rats (Ottolenghi, Haseman, Payne, et al. 1958, in J. National Cancer Inst.

54(5):1165). A recent in-vitro study of the morphological and neoplastic transformation induced by insoluble nickel compounds in mouse embryo cells showed that these substances induced type II foci, some of which were tumorigenic, in these cells (Miura, Patierno, Sakuramoto, and Landolph 1984, in Environ. Mol. Mutagen. 14(2):65-78). Reproductive effects in the form of testicular degeneration were seen in mice and rats exposed to the subsulfide by inhalation at a nickel concentration of 0.9 mg/m3 (Benson, Carpenter, Hahn et al. 1987, in Fund. Appl. Toxicol. 9(2):251).

Many nickel compounds cause dermal sensitivity; the prevalence of nickel sensitivity in the general population is estimated at 2.5 to 5.0 percent (Peltonen 1979, in Contact Dermatitis 5:27]. A recent review (Christensen 1990, in Dermatol. Clin. 8(1):37-40), however, reports that the prevalence of nickel sensitivity among women in the general population may range as high as 10 percent. The symptoms of "nickel itch" begin with itching and may progress to skin lesions, discrete ulcers, and eczema (Fisher 1973, Contact Dermatitis; Phila: Lea & Febiger). Several reports of asthma among nickel-exposed workers also appear in the literature (Tolot, Bordeur, Neulat in Arch. Mal. Prof. Med. Travail. Secur. Soc. 1956:18, p. 291; McConnell, Fink, Schlueter, Schmidt et al. 1973, Ann. Intern. Med 78:888). A recent review of the toxicity of nickel compounds in humans (Coogan, Lalta, Snow, and Costa 1989, in Crit. Rev. Toxicol. 19(4):341-384) addresses the systemic and molecular toxicology, as well as the carcinogenicity, of these substances. This paper notes that the major target organs of systemic toxicity are the kidney and the immune system. Nickel subsulfide roasting in nickel refining is generally accepted as being a carcinogenic process on the basis of studies in refinery workers (Grandjean et al. 1988; Agency for Toxic Substances and Disease Registry 1987). Nickelexposed workers in many other industries (electroplating, alloy manufacture) have also shown a statistically significant increase among these workers (Grandjean et al. 1988, ATSDR 1987). Based on this evidence in humans, the International Agency for Research on Cancer, NIOSH, and the ACGIH have all concluded that nickel is a probable or confirmed human carcinogen. The mechanisms of nickel carcinogenesis are reviewed in a 1989 article by Sunderman (Scand. J. Work. Environ. 15(1):1-12); this author hypothesizes that differences in the carcinogenic activities of nickel

compounds may reflect variations in their capacities to provide nickel ions at critical sites within target cells.

Based on this evidence, OSHA is proposing a limit of 1 mg/m³ as an 8-hour TWA for nickel and its insoluble compounds (measured as nickel) in agricultural operations. The Agency preliminarily concludes that this limit is necessary to protect workers in agriculture from the significant risk of material health impairments in the form of nickel-induced cancer and skin and pulmonary sensitization. In addition, promulgation of this PEL will make OSHA's limit for these substances consistent across all regulated sectors.

NICOTINE
CAS: 54-11-5; Chemical Formula:
C₁₀H₁₄N₂

H.S. No. 2115

OSHA's current permissible exposure limit for nicotine in general industry, construction, and maritime workplaces is an 8-hour TWA of 0.5 mg/m3 this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. OSHA has no PEL for nicotine in agriculture. The ACGIH's current TLV®-TWA for this substance is 0.5 mg/m³, with a skin notation. NIOSH has no REL for nicotine but concurs (Ex. 8-47) with the limit being proposed. OSHA is proposing a TWA PEL of 0.5 mg/m3, with a skin notation, for nicotine in agriculture. Promulgation of this limit will make the PEL for nicotine consistent across all OSHA-regulated

Nicotine is a thick, colorless, pale yellow oil that turns brown on exposure to air and has a slight fishy odor when warm. Nicotine is used as an insecticide and fumigant. It is also used in human medicine and in tanning (ACGIH 1986, p. 427). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Nicotine causes stimulation, followed by depression, of the central and autonomic nervous systems in humans and animals. Nicotine also causes fetotoxic, developmental, and reproductive effects (NIOSH/OSHA Occupational Health Guideline 1981, p. 4; Proctor, Hughes, and Fischman 1988, p. 363). The oral LDso in rats is 50 mg/kg; in mice it is 3.34 mg/kg (RTECS 1990). The dermal LDso in rabbits is 50 mg/kg (RTECS 1990). Nicotine exerts its effect by transiently stimulating, and then severely depressing, the central nervous system; death is due to respiratory paralysis (HSDB 1988). Dogs showed signs of restlessness, apnea followed by

hyperpnea, and a rapid decrease in the strength of respiration terminating in apnea (Franke and Thomas 1933, in Hayes 1982, p. 86). The effects of nicotine poisoning in dogs include fluctuations in blood pressure, convulsions, respiratory failure, and increase in heart rate; these symptoms can result in death (Franke and Thomas 1933, in Hayes 1982, p. 86). Nicotine was teratogenic in mice receiving injections of 25 mg/kg on days 9 through 11 of gestation; skeletal malformations and cleft palates were observed (National Research Council 1977, in HSDB 1988). Deformities were also found in the fetuses of rabbits administered 20 mg/kg of nicotine five times during pregnancy (Crowe 1972, in HSDB 1988). Administered to inbred Fischer and Buffalo rats, nicotine resulted in greatly reduced fertility (Riesenfeld and Oliva 1987, in HSDB 1988).

In small doses, nicotine causes symptoms of vomiting, dizziness, tachycardia, hypertension, sweating, and salivation in humans (Baselt 1980, p. 201). Symptoms of toxicity have been observed in workers harvesting tobacco, probably as a result of dermal absorption of nicotine (Gehlbach et al. 1975, in Baselt 1980, p. 201). Nicotine poisoning in humans is similar to that in animals; signs of poisoning include respiratory failure and circulatory collapse (Beeman and Hunter 1937, in Hayes 1982, p. 90). The estimated minimal lethal dose of nicotine in humans is 40 to 60 mg; this dose causes prostration, convulsions, respiratory paralysis, and death after ingestion (Baselt and Cravey 1977, in Baselt 1980, p. 201). Nicotine splashed in a patient's eye caused severe pain, conjunctival irritation, and corneal infiltration (Villard 1927, in Grant 1974, p. 747). Intravenous injection of 1.0 mg of nicotine alkaloid caused approximately the same increase in blood pressure and heart rate and decrease in skin temperature of the fingers and toes as did smoking a cigarette (Moddock and Collier 1933, in Hayes 1982, p. 90). Nicotine crosses the placental barrier and has been found in the amniotic fluid of smokers (Mosier and Jansons 1972; Van Vunakis et al. 1974, in Clayton and Clayton 1981, p. 2813).

Based on this evidence in humans and animals, OSHA preliminarily concludes that nicotine causes central and autonomic nervous system effects and affects reproduction and fertility. In the absence of a limit, OSHA therefore preliminarily finds that workers in agriculture are at significant risk of experiencing these effects. The Agency believes that establishing an 8-hour TWA PEL of 0.5 mg/m³, with a skin

notation, will substantially reduce these risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. PERCHLOROMETHYL MERCAPTAN CAS: 594–42–3; Chemical Formula: CCl₃SCl

H.S. No. 2125

In general industry, construction, and maritime, OSHA's current permissible exposure limit for perchloromethyl mercaptan is 0.1 ppm as an 8-hour TWA. There is no limit for this substance in agriculture. The ACGIH has a TLV*-TWA of 0.1 ppm. NIOSH has no REL for this substance but concurs (Ex. 8-47) with the limit being proposed. OSHA is proposing a PEL of 0.1 ppm as an 8-hour TWA for perchloromethyl mercaptan in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Perchloromethyl mercaptan is a pale yellow, oily liquid with a disagreeable odor. This substance is used in the production of fungicides, as a fumigant, as a dye intermediate, and in organic synthesis (ACGIH 1986, p. 466; Proctor, Hughes, and Fischman 1988, p. 401). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Perchloromethyl mercaptan is a severe eye, mucous membrane, and pulmonary irritant in humans and animals; accidental overexposure has caused liver and kidney damage and death in humans. The oral LD50 in rats is 83 mg/kg (RTECS 1990). In mice, the LC₅₀ is 296 mg/m³ (37 ppm) for 2 hours (RTECS 1990), and the dermal LD50 in rabbits is 1410 mg/kg (Vernot et al. 1977, in ACGIH 1986, p. 466.1(88)). Rabbits showed signs of severe eye irritation after application of 0.05 mg; applied to the skin, 560 mg also caused severe irritation in these animals (RTECS 1990). Cats and mice exposed to perchloromethyl mercaptan for 15 minutes at a concentration of 45 ppm developed pulmonary edema and died within 1 to 2 days (Althoff 1973, in Proctor, Hughes, and Fischman 1988, p. 401; ACGIH 1986, p. 466). Rats exposed to the vapors of perchloromethyl mercaptan for 6 hours/day, 5 days/week for 2 weeks at concentrations of 0.13, 1.0, or 8.7 mg/m³ (0.01, 0.1, or 1.1 ppm) had labored breathing, tremors, nasal irritation, and pulmonary edema at the highest concentration; no symptoms or effects were observed in rats exposed to lower concentrations (Knapp et al. (no

date), in ACGIH 1986, p. 466.2(88)). Male rats exposed to perchloromethyl mercaptan vapors at a concentration of 2 ppm for 6 hours/day, 5 days/week for 4 weeks exhibited signs of respiratory distress; at autopsy, lung congestion was observed. Exposure to a 0.5-ppm concentration on the same regimen caused no adverse effects (Gage 1970, in ACGIH 1986, p. 466.1(88)).

Exposure to 10 mg/m3 (1.3 ppm) perchloromethyl mercaptan causes eye irritation in humans (Althoff 1973, in Proctor, Hughes, and Fischman 1988, p. 401). Acute exposures cause the following signs and symptoms: coughing. dyspnea, lacrimation, pallor, vomiting, tachycardia, convulsions, and cyanosis; death due to lung edema also may occur (Althoff 1973; Ruth 1986; Spacilova 1971, in ACGIH 1986, p. 466.1(88)). Three chemical workers were accidentally overexposed to an unspecified concentration of perchloromethyl mercaptan vapors; two survived subsequent episodes of pulmonary edema, but the third died 36 hours later. At autopsy, necrotizing tracheitis, massive hemorrhagic pulmonary edema, toxic nephrosis, and vacuolization of centrilobular hepatic cells were seen (Althoff 1973, in Proctor, Hughes, and Fischman 1988, p. 401).

Based on this evidence in humans and animals, OSHA preliminarily concludes that perchloromethyl mercaptan causes severe eye and pulmonary irritation and liver and kidney damage. In the absence of a limit, OSHA believes that workers in agriculture are at significant risk of experiencing these effects, which are material health impairments. The Agency preliminarily finds that the proposed PEL of 0.1 ppm as an 8-hour TWA is necessary to substantially reduce these significant risks. This action would also make the PEL for perchloromethyl mercaptan the same for workplaces in all OSHA-regulated sectors.

PHENOL CAS: 108–95–2; Chemical Formula: C₆H₅OH H.S. No. 2126

OSHA's current permissible exposure limit for phenol in general industry, construction, and maritime is 5 ppm as an 8-hour TWA; this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. There is no limit in agriculture. The ACGIH has a TLV*-TWA limit of 5 ppm, with a skin notation, for phenol. NIOSH has RELs for phenol of 5.2 ppm as a 10-hour TWA and 15.6 ppm as a 15-minute ceiling. OSHA is proposing an 8-hour TWA PEL of 5 ppm, with a skin

notation, for phenol in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Phenol consists of white or clear crystals that turn pinkish or reddish in color on exposure to air or light. This substance is used as a disinfectant, in germicidal paints and slimicides, and in the manufacture of phenolic resins, bisphenol-A, caprolactam, and a variety of other chemicals and drugs (ACGIH 1986, p. 469; Hawley's 1987, p. 897). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Phenol causes irritation of the eyes, mucous membranes, and skin and central nervous system effects in humans and animals. Phenol is also corrosive in contact with the skin or eyes. In rats and mice, oral LD50 values are 317 mg/kg and 270 mg/kg, respectively, and the LCoos in rats and mice are 316 mg/kg and 177 mg/kg, respectively (RTECS 1990). The dermal LD50 in rabbits is 850 mg/kg; in rats it is 669 mg/kg (RTECS 1990). In contact with the skin of rabbits, 500 mg of phenol caused severe irritation; instilled into the eyes of rabbits, 5 mg also caused a severe degree of irritation (RTECS 1990). In a study by Pullin et al. (1978, in ACGIH 1986, p. 469), swine were given skin applications of 500 mg/kg over 35 to 40 percent of the body area for 1.0 and 2.5 minute periods to study the percutaneous absorption effects of phenol. The phenol was absorbed rapidly through the skin and caused twitching and tremors within 3 to 5 minutes. After 5 minutes, signs of excessive salivation, nasal discharge, and respiratory distress were observed; 1.75 hours after exposure, animals were found to have a peak plasma phenol concentration of 52.6 ppm (Pullin et al. 1978, in ACGIH 1986, p. 469). Guinea pigs exposed to phenol concentrations of 25 to 50 ppm for 20 days died; autopsy revealed severe injury of the heart. lungs, liver, and kidneys (Deichmann 1944, in ACGIH 1986, p. 469). Mice treated weekly for 42 weeks by application of one drop of phenol in benzene to shaved skin developed papillomas (5 of 14 mice) after 52 weeks (NIOSH Criteria Document 1976). Although phenol is considered noncarcinogenic in rats or mice, increased incidences of leukemia and lymphoma were detected in male rats given 2500 or 5000 ppm in their drinking water for 103 weeks (National Cancer Institute 1980, in Proctor, Hughes, and Fischman 1988, p. 404).

The lowest lethal oral dose in adult humans is 14 mg/kg (RTECS 1990). Brief industrial exposures to phenol concentrations of 48 ppm (in combination with 8 ppm formaldehyde) caused marked eye, nose, and throat irritation (NIOSH Criteria Document 1976). The signs and symptoms of human overexposure to phenol include loss of appetite, darkened urine, muscle pain, rapid and weak pulse, difficult breathing, cyanosis, convulsions, and coma; death may occur if the overexposure is severe (Merliss 1972; Stajduhar-Caric 1968, in Rom 1983, p. 528). Phenol is highly corrosive to the skin and causes a whitening of the contacted area (Key, Henschel, Butler et al. 1977, in Rom 1983, p. 528). A recent NIOSH study (O'Malley, Mathias, Priddy, Molina, Grote, and Halperin 1988, J. Occup. Med. 30(6):512-516) reports that workers handling rubber that contained phenol developed chemically induced vitiligo (skin depigmentation). In contact with the eyes, phenol causes severe damage and may lead to permanent loss of vision (Grant 1986, p. 720). Ingestion of as little as 10 g causes severe mouth and throat burns, tremor, convulsions, and muscle twitching (NIOSH Criteria Document 1976; U.S. EPA Summary 1986; in Proctor, Hughes, and Fischman 1988, p. 404). A laboratory technician exposed to vapors and to liquid phenol spilled on the skin experienced symptoms of anorexia, weight loss, weakness, muscle pain, and dark urine; after brief improvement, the patient suffered a worsening of symptoms, including tenderness and enlargement of the liver (Merliss 1972, in Proctor, Hughes, and Fischman 1988, p. 404). A 32-year old male who spilled a strong solution of phenol over his upper body died 10 minutes later; the victim suffered coagulation necrosis of the skin and left eye, acute dermatitis veneta, acute passive congestion of the lungs, liver, spleen, and kidneys, and "acute phenol toxicosis" (Gottlieb and Storey 1936, in ACGIH 1986, p. 470).

Based on this evidence in humans and animals, OSHA preliminarily concludes that phenol causes eye, skin, and mucous membrane irritation and central nervous system effects in exposed workers. This substance is also corrosive on contact with the skin or eyes and is rapidly absorbed through the skin. The Agency preliminarily finds that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. OSHA believes that establishing a PEL of 5 ppm as an 8-hour TWA, and a skin notation, is necessary to

substantially reduce these risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

PHENYLHYDRAZINE
CAS: 100-63-0; Chemical Formula:
CaH₆NHNH₂
H.S. No. 1317

OSHA's current limit for phenylhydrazine in construction and maritime is 5 ppm as an 8-hour TWA, with a skin notation. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 5 ppm and a TLV®-STEL of 10 ppm, and a skin notation, for this substance. The ACGIH considers this substance a potential human carcinogen and assigns it an A2 classification. NIOSH considers this substance a potential occupational carcinogen and (1978e/Ex. 1-263) recommends that workplace exposures not exceed 0.14 ppm, measured over a 2-hour period. In construction and maritime, OSHA is proposing to retain the 8-hour TWA PEL of 5 ppm and the skin notation and to add a STEL of 10 ppm; OSHA is also proposing to extend these limits to agriculture. These are the limits recently established for phenylhydrazine in general industry.

Phenylhydrazine may take the form either of yellow crystals or an oily liquid that darkens on exposure to air and light. It is used as a reagent in analytical chemistry and in organic synthesis. The hydrochloride is a strong reducing agent

(Hawley's 1987, p. 903).

No data are available on the effects of phenylhydrazine resulting from inhalation. OSHA's limits are based on the high acute toxicity of the compound when administered orally or subcutaneously to animals; single doses on the order of 20 mg/kg have resulted in the death of dogs within 22 days (Hesse, Franke, and Hering 1935/Ex. 1-785) and produced a marked decrease in erythrocyte count in rodents (von Oettingen and Deichmann-Greubler 1936/Ex. 1-771). Anemia and hemolysis are the characteristic responses seen in animals fed or injected with phenylhydrazine.

In its criteria document on the hydrazines, NIOSH (1978e/Ex. 1-263) reviewed four studies on the carcinogenicity of phenylhydrazine in mice. One study (Toth and Shimizu 1976/Ex. 1-675) found significant increases in blood vessel tumors. Another study (Clayson, Biancifiori, Milia, and Santilli 1966, as cited in ACGIH 1986/Ex. 1-3, p. 477) reported increased incidences of lung adenomas and adenocarcinomas. Two other studies (Roe, Grant, and Millican 1967/

Ex. 1–659; Kelly, O'Gara, Yancy et al. 1969/Ex. 1–703) were negative. NIOSH concluded that phenylhydrazine should be considered a potential human carcinogen and recommended that exposures not exceed 0.14 ppm over a 2-hour sampling period, which represents the lowest level that can be detected reliably. The ACGIH (1986/Ex. 1–3) has placed phenylhydrazine on its A2 (suspected human carcinogens) list.

In the prior rulemaking, several commenters (Exs. 8-47; Tr. 3-97 to 3-98, 116, 195, Tr. 9-218, 8-16) were of the opinion that a lower PEL was warranted for phenylhydrazine. OSHA is aware of the developing literature on phenylhydrazine. However, the primary objective of the present rulemaking is to ensure consistency in OSHA's limits across sectors. At the time of the first PEL update, OSHA will evaluate the toxicologic literature on phenylhydrazine to determine whether there is a need at that time for a further reduction in the occupational exposure limit.

However, at the present time, OSHA is retaining the 5-ppm 8-hour TWA limit and skin notation and is proposing to add a 10-ppm STEL for phenylhydrazine in construction and maritime; OSHA is also proposing to extend these limits to agriculture. The Agency preliminarily concludes that these limits will reduce the significant health risks associated with exposure to this substance among workers in these sectors. These risks include acute blood-related toxicity and may also include cancer; these effects clearly constitute material impairments of health. Promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

PHENYLPHOSPHINE
CAS: 638-21-1; Chemical Formula:
C₆H₅PH₂
H.S. No. 1318

OSHA has no PEL for phenylphosphine in construction, maritime, or agriculture; NIOSH also has no REL for this substance. The ACGIH has a TLV*-ceiling of 0.05 ppm for phenylphosphine. The proposed PEL is a ceiling of 0.05 ppm; NIOSH concurred (Ex. 8-47, Table N1) with this limit when it was recently established in general industry.

Phenylphosphine is a crystalline solid that is used in catalysts and antioxidants (Sittig 1985, p. 712).

A 90-day inhalation study conducted by the du Pont Company, in which rats and beagle dogs were exposed to average concentrations of 0.6 ppm or 2.2 ppm phenylphosphine for 6 hours per day, 5 days per week, showed that rats

exposed to 2.2 ppm had significant hematologic changes and testicular degeneration (E.I. du Pont de Nemours & Co., Inc. 1970, as cited in ACGIH 1986/ Ex. 1-3, p. 479). These effects were not noted among rats exposed to 0.6 ppm. but rats exposed at the lower level did show hypersensitivity to sound and touch and mild hyperemia. The dogs tolerated the higher exposure level better than the rats in that some regeneration of testicular damage occurred in dogs during a 1-month recovery period. Dogs exposed to 0.6 ppm exhibited intermittent nausea, diarrhea, lacrimation, and hind leg tremor (ACGIH 1986/Ex. 1-3). The ACGIH considered 0.6 ppm to be an NOE level for severe effects in animals and recommended a 0.05-ppm ceiling TLV* to provide a tenfold safety margin to protect workers against the changes exhibited by the test animals at the 0.8ppm level.

OSHA preliminarily concludes that workers in construction, maritime, and agriculture who are exposed to uncontrolled levels of phenylphosphine are at significant risk of experiencing the nausea, irritation, and CNS effects found to be associated with such exposures. OSHA preliminarily finds that these effects constitute material health impairments. The Agency believes that the proposed ceiling of 0.05 ppm for phenylphosphine in construction, maritime, and agriculture will reduce these significant risks substantially. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

PHOSPHINE

CAS: 7803-51-2; Chemical Formula: PH₃ H.S. No. 1321

OSHA currently has a PEL of 0.3 ppm TWA for phosphine in construction and maritime. There is no limit in agriculture. The ACGIH recommends a TLV*-TWA of 0.3 ppm and a TLV*-STEL of 1 ppm. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limits being proposed. OSHA is retaining the 8-hour TWA limit of 0.3 ppm and proposing to add a 1 ppm STEL for phosphine in construction and maritime; the Agency is also proposing to extend these limits to agriculture. These are the limits recently established for this substance in general industry.

Phosphine is a colorless gas with a disagreeable, garlic-like odor. Phosphine is used primarily as a fumigant. It is also used in chemical synthesis and as a doping agent for electrical components (ACGIH 1986, p. 482). When used in pesticidal applications and in

accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Early studies reported that laboratory animals could tolerate phosphine in 4-hour daily exposures of 5 ppm for 2 months, but fatalities were observed from seven similar exposures at 10 ppm (Muller 1940/Ex. 1–919). In 1975, Waritz and Brown (Ex. 1–451) reported a 4-hour LC₅₀ of 11 ppm in rats; these lethal exposures caused effects typical of

respiratory irritation.

Prior to 1958, numerous cases of phosphine-related occupational poisonings and deaths were reported, including a fatality caused by pulmonary edema that was attributed to an exposure of 8 ppm for 2 hours daily (Harger and Spolyar 1958/Ex. 1-327). Sublethal symptoms (without chronic effects) occurred at phosphine exposures averaging 10 ppm or less, with excursions of up to 35 ppm; recorded symptoms included diarrhea, nausea, vomiting, respiratory distress, and dizziness (Jones, Jones, and Longley 1964/Ex. 1-420). The literature contains no documented reports of chronic poisoning caused by prolonged exposure to phosphine, although several authorities have asserted that this is a possibility (Henderson and Haggard 1943e/Ex. 1-1086; Fairhall 1957h, as cited in ACGIH 1986/Ex. 1-3, p. 883; Johnstone and Miller 1960/Ex. 1-1114; Patty 1963f, as cited in ACGIH 1986/Ex. 1-3, p. 883; American Industrial Hygiene Association (AIHA) 1964/Ex. 1-407).

In the earlier rulemaking, Joel Carr, Health and Safety Research Director for the American Federation of Grain Millers Union, testified on the toxicology of and employee exposures to phosphine in grain elevators and flour mills (Ex. 8-1; Tr. pp. 7-240 to 7-259). Mr. Carr described a report of a group of industrial hygiene studies published by NIOSH (Zaebst 1986; Zaebst, Blade, Morelli-Schroth et al. 1987; Zaebst, Blade, Burroughs et al. 1988), in which applicators of phosphine were found to be exposed above the proposed TWA PEL and STEL; nonapplicator workers also become exposed while working near fumigated grain, while loading or transferring fumigated grain, or while working in elevators and mills. OSHA believes that workers handling treated grain in agricultural settings and in marine terminal and longshoring operations would be likely to have exposures similar to those described by Mr. Carr.

Based on this evidence, OSHA is retaining its 8-hour TWA PEL of 0.3 ppm and proposing to add a 15-minute STEL of 1 ppm for phosphine in the construction and maritime sectors and is additionally proposing to extend these limits to agriculture. The Agency preliminarily concludes that both of the proposed limits are necessary to substantially reduce the significant risk of lung damage, diarrhea, and nausea, all material health impairments associated with elevated short-term and long-term exposure to this toxic gas. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

PHOSPHORUS, YELLOW CAS: 7723-14-0; Chemical Formula: P₄ H.S. No. 2130

OSHA's permissible exposure limit for yellow phosphorus in general industry, construction, and maritime is 0.1 mg/m³ as an 8-hour TWA. There is no limit in agriculture. The ACGIH has an 8-hour TLV®-TWA of 0.1 mg/m³ for yellow phosphorus. NIOSH has no REL for this substance. OSHA is proposing an 8-hour TWA limit of 0.1 mg/m³ for yellow phosphorus in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Yellow phosphorus is a yellow, soft, waxy, crystalline solid that darkens on exposure to light and has a distinct garlic-like odor. It is used in the manufacture of rat poisons, fertilizers, and fireworks, in gas analysis, and to produce smoke screens (ACGIH 1986, p. 484; Gosselin, Smith, and Hodge 1984, p. III–348; Proctor, Hughes, and Fischman 1988, p. 412). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Yellow phosphorus causes eye, skin, and respiratory tract irritation and burns, bone changes, and kidney and liver injury in humans and animals. The oral LD50 in rats is 3030 mg/kg, and in mice it is 4820 mg/kg (RTECS 1991). Inhalation of phosphorus vapors at concentrations of greater than 20 ppm for 7 hours/day, 5 days/week caused severe respiratory irritation and a high mortality rate in rats as a result of lung edema and bronchopneumonia (ACGIH 1986, p. 484). Subcutaneous injection of rats with 0.05 mg/kg of yellow phosphorus per day caused the development of bone changes; 0.8 mg/ kg/day resulted in an increased death rate (Fleming et al. 1942, in J. Ind. Hyg. Tox. 24:154). Dogs subcutaneously injected with 0.2 to 0.4 mg/kg/day yellow phosphorus died within a few days (Buchanan et al. 1954, in Arch. Ind. Hyg. Occup. Med. 9:1). Experimental animals exposed to 13 to 16 ppm of

phosphorus for 7 hours a day, 5 days a week for 4 months showed no difference in growth patterns as compared with controls (unpublished TVA Report 1947, cited in ACGIH 1986, p. 484). Repeated doses of 0.1 mg/kg/day of yellow phosphorus caused chronic poisoning and liver damage in dogs (Buchanan et al. 1954, in Arch. Ind. Hyg. Occup. Med. 9:1).

In humans, yellow phosphorus has caused death from a single 1-mg/kg dose (Smyth 1956, Am. Ind. Hyg. Assoc. Q. 17:129), and as little as 0.2 mg/kg can produce adverse effects (Diaz-Rivera et al. 1950, in Medicine 29:269, as cited in Clayton and Clayton 1981, p. 2122). Yellow phosphorus fumes are irritating to the respiratory tract and eyes; exposure causes severe irritation, with blepharospasm, photophobia, and lacrimation (Scherling and Blondi's 1945, in Mil. Surg. 96:70-78, as cited in Grant 1986, p. 735). Yellow phosphorus causes deep, painful burns of the skin, producing a firm eschar surrounded by vesiculation (Summerlin et al. 1967, in J. Trauma 7:476-484, as cited in Proctor, Hughes, and Fischman 1988, p. 412). Signs and symptoms of yellow phosphorus intoxication include abdominal pain, jaundice, and a garlic odor of the breath (Proctor, Hughes, and Fischman 1988, p. 412). Severe acute yellow atrophy of the liver is a delayed symptom of yellow phosphorus poisoning that may prove fatal (Klaassen, Amdur, and Doull 1986, p. 567). A Russian study (Beloskurskaia, Aitbembetov, Balmakhaeva, Korolćhuk 1989, in Vrach Delo 7:104-106) of 600 vellow phosphorus production workers showed that the liver toxicity associated with chronic phosphorus poisoning was a result of impaired fat metabolism. Chronic poisoning from yellow phosphorus can cause anemia, cachexia, and necrosis of the bone, and particularly of facial bones, including the maxilla and mandible (Proctor, Hughes, and Fischman 1988, p. 4121 Phosphorus necrosis of the jaw ("phossy jaw") was common among match workers early in this century and has more recently been reported among chemical and fireworks industry workers (Heimann 1946, in J. Ind. Hyg. Tox. 28:142; Hughes et al. 1962, in Brit. J. Ind. Med. 19:83; Nomura 1956, in J. Sci. Labour (Japan) p. 109). Phossy jaw is the result of the oral absorption of small quantities of phosphorus over a long period of time. A recent Japanese study (Horiguchi, Endo, Nakano, Shinagawa, and Harima 1988, in Sumitomo Bull. Ind. Hlth. 24:27-32) reports several cases of phosphorus necrosis among workers exposed before 1974 to phosphorus in

phosphoric acid, phosphoric acid fertilizer, and yellow phosphorus

production plants.

Based on this evidence in humans and animals, OSHA preliminarily concludes that yellow phosphorus causes eye, skin, and respiratory tract irritation, bone degeneration, and kidney and liver injury in exposed workers. OSHA therefore believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency preliminarily finds that a limit of 0.1 mg/ ms as an 8-hour TWA is necessary to significantly reduce these risks of material health impairment. In addition, promulgation of this limit will make the PEL for yellow phosphorus consistent across all OSHA-regulated sectors. PIPERAZINE DIHYDROCHLORIDE CAS: 142-64-3; Chemical Formula:

C₄H₁₀N₂•2HCl H.S. No. 1330

OSHA has no limit for piperazine dihydrochloride in construction, maritime, or agriculture. The ACGIH recommends a TLV*-TWA limit of 5 mg/m³. There is no NIOSH REL; however, NIOSH concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing a 5 mg/m³ 8-hour TWA limit for this substance in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry.

Piperazine dihydrochloride is a white, water-soluble solid in the form of needles. This substance is used in the manufacture of insecticides, pharmaceuticals, and fibers (Hawley's 1987, p. 921). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

This substance has low systemic toxicity and mild irritant properties; the compound is biologically active. The oral LD50 for rats has been reported as 4.9 g/kg (NIOSH 1984, as cited in ACGIH 1986/Ex. 1-3, p. 491). Eye and skin irritation have been reported as a result of human exposures to high (not further specified) levels of piperazine dihydrochloride; subjects experienced mild to moderate skin burns and sensitization. Inhalation of the dust has been associated with asthmatic reactions (Dow Chemical Company 1977h, as cited in ACGIH 1986/Ex. 1-3, p. 491).

OSHA is proposing to establish a limit of 5 mg/m³ as an 8-hour TWA for piperazine dihydrochloride in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit is necessary to reduce the

significant risks of sensitization and eye and skin irritation, material health impairments that are potentially associated with exposure to this substance at levels above the proposed limit. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

N-PROPYL NITRATE
CAS: 627-13-4; Chemical Formula:
CH₂CH₂CH₂ONO₂
H.S. No. 1340

OSHA currently has an 8-hour TWA limit of 25 ppm for n-propyl nitrate in the construction and maritime industries. There is no limit in agriculture. The ACGIH has a 25-ppm TLV®-TWA and a 15-minute TLV®-STEL of 40 ppm. NIOSH has no REL but concurs [Ex. 8-47, Table N1) with the limits being proposed. OSHA is retaining the 25 ppm 8-hour TWA limit and proposing to add a 40 ppm STEL for this substance in construction and maritime; the Agency is also proposing to extend these limits to agriculture. These are the limits recently established for this substance in general industry.

N-Propyl nitrate is a pale yellow liquid with a sickly sweet odor. It is used as an intermediate in chemical synthesis and as a fuel ignition promoter

(ACGIH 1986, p. 505).

Rats inhaling propyl nitrate vapor for 4 hours at a concentration of 10,000 ppm exhibited cyanosis and methemoglobinemia before they died (Hood 1953, as cited in ACGIH 1986/Ex. 1-3, p. 505). The intravenous LD50 in unanesthetized rabbits has been reported to be between 200 and 250 mg/ kg; in anesthetized dogs and cats, intravenous doses of between 100 and 200 mg/kg were usually fatal (Murtha, Stabile, and Wills 1956/Ex. 1-649). The authors of these studies (1956/Ex. 1-649) concluded that n-propyl nitrate exerts a direct action on the vascular smooth muscle and that the ensuing cardiac effects and respiratory depression contribute to the compound's hypotensive action (Murtha, Stabile, and Wills 1956/Ex. 1-649). Inhalation trials in mice, rats, hamsters, guinea pigs, and dogs have established 4-hour LCso values ranging from 9000 to 10,000 ppm for rats, 6000 to 7000 ppm for mice, and 2000 to 2500 ppm for dogs. Dogs survived repeated exposures (6 hours/ day, 5 days/week) at 260 ppm for 6 months, although slight clinical signs were observed during the first 2 weeks of exposure (Rinehart, Garbers, Greene, and Stoufer 1958/Ex. 1-524). The percutaneous toxicity of n-propyl nitrate is low, but this substance may cause inflammation and thickening of the skin

after repeated exposures; these effects are sometimes transient (ACGIH 1986/Ex. 1-3, p. 505).

In construction and maritime, OSHA is retaining the PEL of 25 ppm as an 8hour TWA and proposing to add a STEL of 40 ppm for n-propyl nitrate; the Agency is also proposing to extend these limits to agriculture. The Agency preliminarily concludes that these limits will protect workers in these sectors against the significant risk of cyanosis, methemoglobinemia, and hypotension, all material health impairments that are potentially associated with exposure to n-propyl nitrate. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

PYRETHRUM CAS: 8003-34-7; Chemical Formula: C₂₁H₂₈O₃ or C₂₂H₂₈O₅ H.S. No. 2136

In general industry, construction, and maritime, OSHA's current permissible exposure limit for pyrethrum is 5 mg/m³ as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 5 mg/m³ for pyrethrum. NIOSH has no REL for this substance but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA limit of 5 mg/m³ for pyrethrum in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Pyrethrum is an insecticide extracted from chrysanthemums; it is a viscous brown resin or solid composed of six active principles: Pyrethrins I and II, cinerins I and II, and jasmolin I and II. Pyrethrum is used as a botanical insecticide (ACGIH 1986, p. 506; New Jersey Fact Sheet 1986, p. 1). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Pyrethrum causes dermatitis, sensitization, and central nervous system effects in humans and animals. The oral LD₅₀s in rats and mice are 200 mg/kg and 370 mg/kg, respectively (RTECS 1990). The dermal LD50 in rats is greater than 1800 mg/kg (ACGIH 1986, p. 508). An intravenous pyrethrum dose of 5 mg/kg caused behavioral symptoms and convulsions in rats (RTECS 1990). The acute effects of pyrethrum poisoning in animals include excitation, convulsions, tetanic paralysis, and muscular fibrillation (Chevalier and Ripert 1927, in Hayes 1982, p. 76). Death is usually due to respiratory failure (Chevalier 1930, Shimkin and Anderson

1938, Leonard 1942, Chevalier and Ripert 1927, in Hayes 1982, p. 76). Rats exposed once to 6000 mg/m3 of pyrethrum in peanut oil for 30 minutes showed moderate lung congestion at autopsy (Carpenter, Weil, Pozzani, and Smyth 1950, in ACGIH 1986, p. 508). A pyrethrum concentration of 18 mg/m3 inhaled by rats and dogs for 30-minute periods over 31 days caused only slight lung irritation (Carpenter, Weil, Pozzani, and Smyth 1950, in ACGIH 1986, p. 506). Dogs showed signs of tremor, ataxia, labored respiration, and excess salivation when fed pyrethrins at a dietary level of 5000 ppm for 90 days (Griffin 1973, in Hayes 1982, p. 77). The only significant effects seen in male and female rats fed dietary levels of pyrethrin (equivalent to 10, 50, or 250 mg/kg) for 2 years was slight but definite liver damage in animals exposed at the higher dose levels (Lehman 1965, in Hayes 1982, p. 77). Rats given daily gavage doses of 50, 100, or 150 mg/kg on days 8 to 15 of pregnancy had a higher incidence of resorptions compared with controls, and rats fed a dietary pyrethrum level of 5000 ppm beginning 3 weeks before first mating had weanlings whose weights were significantly lower than those of controls (Khera et al. 1982, in Proctor, Hughes, and Fischman 1988, p. 430; Griffin 1973, in Hayes 1982, p. 78).

The most common effect of exposure to pyrethrum in humans is dermatitis, which is usually manifested as a mild erythematous dermatitis with vesicles, papules in moist areas, and intense pruritus; a bullous dermatitis may also develop (Hayes 1963, in Proctor, Hughes. and Fischman 1988, p. 430). The lowest lethal oral dose of pyrethrum in humans is 1 g/kg (RTECS 1990). In pure form, pyrethrum constituents pyrethrin I and II are reported to be irritating to the eyes and mucous membranes (Grant 1986, p. 774). In a study of workers processing pyrethrum powder, 30 percent were found to have erythema, skin roughening, and pruritus; these effects cleared after cessation of exposure (Casida 1973, in Proctor, Hughes, and Fischman 1988, p. 430). A sensitization reaction has been reported in a worker exposed to pyrethrum dust; the signs and symptoms associated with this episode included reddening, burning, itching, and swelling of the cheeks, eyes, and face and severe pruritus. These effects disappeared within 2 days after the cessation of exposure [Casida 1973. in Proctor, Hughes, and Fischman 1988, p. 430). The symptoms of sensitivity to pyrethrum may resemble those seen in pollinosis: sneezing, nasal discharge.

and nasal stuffiness (Feinberg 1934; Ramirez 1930, in Hayes 1982, p. 79).

Based on this evidence, OSHA preliminarily concludes that pyrethrum causes dermatitis, skin sensitization, and eye and nose irritation in exposed workers. OSHA therefore believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that establishing a PEL of 5 mg/m3 as an 8hour TWA for pyrethrum in agriculture is necessary to significantly reduce these risks of material health impairment. In addition, promulgation of this limit will make the PEL for this substance consistent across all OSHAregulated sectors.

PYRIDINE CAS: 110-86-1; Chemical Formula: C₆H₅N

H.S. No. 2137

In general industry, construction, and maritime, OSHA's current permissible exposure limit for pyridine is 5 ppm as an 8-hour TWA. There is no limit for this substance in agriculture. The ACGIH has a TLV*-TWA of 5 ppm for pyridine. NIOSH has no REL for this substance but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA limit of 5 ppm for pyridine in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Pyridine is a flammable, colorless to yellow liquid with a strong and disagreeable odor. Pyridine is used as a fungicide, in the synthesis of vitamins and drugs, as a solvent, an alcohol and antifreeze denaturant, and a dyeing assist (ACGIH 1986, p. 507; Hawley's 1987, p. 982). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Pyridine causes eye, skin, and mucous membrane irritation, central nervous system effects, bone marrow changes. and liver and kidney damage in humans and animals. The oral LDsos in rats and mice are 891 mg/kg and 1500 mg/kg. respectively (RTECS 1990). The dermal LD₅₀ in rabbits is 1121 mg/kg (RTECS 1990). The mean lethal concentration in rats is 4000 ppm for 4 hours [RTECS 1990). Severe eye irritation [graded 7 on an ascending severity scale of 1 to 10) developed in rabbits when 2 mg of pyridine was put into their eyes; in contact with the skin for 24 hours, pyridine caused mild irritation in rabbits (RTECS 1990). In animals, the major effects from exposure to large doses of pyridine by any route include irritation

and narcosis; liver and kidney damage occur after repeated feedings (Clayton and Clayton 1981, p. 2728).

The vapor of pyridine causes eye and nasal irritation, and prolonged or repeated contact of pyridine with the skin results in skin irritation (ACGIH 1988, p. 507; Proctor, Hughes, and Fischman 1988, p. 431). Exposure to 10 ppm pyridine caused a mild degree of irritation in some volunteers (Smyth 1956). A 29-year-old woman developed symptoms of nervous system inhibition, speech disorders, and diffuse cortical affliction after breathing pyridine vapors at an unspecified concentration for 15 to 20 minutes; symptoms were not detected until 10 hours after exposure [Kuzelova et al. 1975, in HSDB 1988). Symptoms of nausea, headache, insomnia, nervousness, low back pain, and frequent urination have occurred in workers exposed to concentrations of pyridine averaging 125 ppm for 4 hours/ day for 1 to 2 weeks (Reinhardt 1981, in ACGIH 1986, p. 507). An epileptic patient being treated with 1.8 to 2.5 ml pyridine daily for 2 months developed serious liver and kidney damage (Pollack et al. 1943, in Proctor, Hughes, and Fischman 1988, pp. 430-431). The most important effects of chronic pyridine inhalation are on the liver. kidneys, and bone marrow (Smyth 1956, in ACGIH 1986, p. 507). Chronic exposure of chemical plant workers to pyridine concentrations ranging from 6 to 12 ppm caused symptoms of central nervous system depression such as headache, vertigo, nausea, and vomiting (Teisinger 1948, in Proctor, Hughes, and Fischman 1988, p. 430).

Based on this evidence in humans and animals, OSHA preliminarily concludes that pyridine causes irritation, central nervous system effects, and liver and kidney damage. OSHA believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these exposure-related effects. The Agency preliminarily concludes that establishing a PEL of 5 ppm as an 8-hour TWA for pyridine in agriculture is necessary to substantially reduce the risk of these material health impairments. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

SELENIUM AND COMPOUNDS (as Se) CAS: 7782–49–2; Chemical Formula: Se H.S. No. 2140

In construction and maritime, OSHA's permissible exposure limit for selenium and its compounds (measured as selenium) is 0.2 mg/m³ as an 8-hour TWA. There is no limit in agriculture.

The ACGIH has a TLV*-TWA of 0.2 mg/m³ for selenium and compounds.

NIOSH has no REL. OSHA is proposing an 8-hour TWA PEL of 0.2 mg/m³ for selenium and its compounds in agriculture. Promulgation of this limit will make the PEL for these substances consistent across all OSHA-regulated sectors.

Selenium is a non-metallic dark red to blush black solid; it may also take the form of dark red, gray, or black crystals. Selenium and its compounds are used as insecticides and in the manufacture of glass, pigments, xerography, rectifiers, steel, photography, catalysts, and rubber; selenium compounds are also used to treat various human and animal diseases (ACGIH 1986, p. 517; Clayton and Clayton 1981, p. 2130). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Selenium and its compounds cause eye, skin, and mucous membrane irritation, central nervous system effects, gastrointestinal disturbances, and loss of hair and fingernails. The oral LD₅₀ in rats is 6700 mg/m³; rats given this dose showed somnolence, dyspnea, and nutritional and metabolic changes (RTECS 1990). The lowest lethal inhalation dose in rats is 33 mg/m3 for 8 hours, at which level hemorrhage, emphysema, and acute pulmonary edema were seen (RTECS 1990). Of the selenium compounds, sodium selenate has the lowest oral LD50, which is 2.3 mg/kg in rabbits (ACGIH 1986, p. 517). Selenium sulfide has an oral LD₅₀ of 370 mg/kg in mice (ACGIH 1986, p. 517). Animals exposed to selenium anhydride at a concentration of 150 mg/m3 for 4 hours showed signs of conjunctivitis, pulmonary edema, and convulsions prior to death; degenerative changes in the liver, kidneys, spleen, and heart were seen at autopsy (NIOSH/OSHA Occupational Health Guideline 1981, p. 2). Animals fed diets containing 5 to 15 ppm of selenium developed hepatic necrosis, hemorrhage, and cirrhosis; some species also developed marked progressive anemia (National Research Council 1980, in Proctor, Hughes, and Fischman 1988, p. 439). Chronic exposure can cause a condition called "alkali disease," which is characterized by emaciation, lack of vitality, loss of hair, and deformities of the bones that cause pain and lameness; animals may also be anemic, have congestive heart failure, cirrhosis of the liver, scarring of the kidneys, and joint erosion of the long bones (Radeleff 1964, in Hayes 1982, p. 54). Eleven of 53 rats developed livercell adenomas or low-grade carcinomas; 43 of 53 rats developed cirrhotic livers, and four rats developed advanced adenomatoid hyperplasia after surviving on diets of 5, 7, or 10 mg selenium per kg of diet for 18 to 24 months (Nelson et al. 1943, in IARC 1975, Vol. 9, p. 251). Rats fed selenium at concentrations of 4, 6, 8, or 16 mg/kg of diet died of toxic hepatitis within 100 days (Harr et al. 1967, in IARC 1975, Vol. 9, p. 252). Selenium also causes reproductive effects in mice and premature death in young mice and rats (Schroeder and Mitchener 1971b, in IARC 1975, Vol. 9, p. 253).

The lowest toxic dermal dose for a selenium compound in humans is 2 mg/ kg for selenium oxychloride (RTECS 1990). Acute industrial exposure to selenium causes symptoms of mucous membrane irritation, sneezing, coughing, eye redness, difficult breathing, frontal headache, and dyspnea in exposed workers (Clinton 1947, in Clayton and Clayton 1981, p. 2131). Garlic breath is a classic symptom of selenium exposure (Rom 1983, p. 499). Selenium dioxide splashed into the eye can cause the development of a pink allergic-type reaction of the eyelids; there may also be conjunctivitis of the palpebral conjunctiva (Glover 1970, in Clayton and Clayton 1981, p. 2131). After being accidentally sprayed in the eyes with selenium dioxide, a chemist experienced burns of the skin, eye irritation, blurred vision, and dulling of the cornea; the eyes had returned to normal 16 days later (Middleton 1947, in Proctor, Hughes, and Fischman 1988, p. 438). Symptoms of mucous membrane irritation, pulmonary edema, bronchitis, and bronchial pneumonia occurred after an accidental poisoning from hydrogen selenate (Olson 1986, in Proctor, Hughes, and Fischman 1988, p. 437). Workers exposed to unspecified concentrations of selenium oxide developed bronchospasm and dyspnea; after 12 hours, they developed metal fume fever, with symptoms such as chills, fever, and headache. A few of these workers developed bronchitis and pneumonitis. but all of the workers were asymptomatic within a week (Wilson 1962, in Proctor, Hughes, and Fischman 1988, p. 438). In China, a disease that was characterized by symptoms of hair and nail loss, skin lesions, nervous system abnormalities, paralysis, and hemiplegia was attributed to chronic selenium poisoning (Yang et al. 1983, in PH&F 1988, p. 438). Unaffected people had an average daily selenium intake of 0.1 mg, while six sick individuals had an average daily intake of 5.0 mg; there were no reports of disabling chronic

disease or death from these exposures (Yang 1983, in Proctor, Hughes, and Fischman 1988, p. 438). In a plant producing selenium rectifiers, 35 of 62 workers reported experiencing various symptoms including headache; nine workers were found to have conjunctivitis and slight tracheobronchitis (Kinningkeit 1962, in ACGIH 1986, p. 517). A group of 200 to 300 workers in a similar plant experienced symptoms of garlic odor of breath, skin rashes, indigestion, metallic taste, and socio-psychological effects; urinary selenium concentrations among these workers ranged from 0.25 mg/ml to 0.43 mg/ml, and air concentrations ranged from 0.2 mg/m3 to as high as 3.6 mg/m3 (Glover 1970; Glover 1967, in ACGIH 1986, p. 517). According to the International Agency for Research on Cancer, there is inadequate evidence to evaluate the carcinogenicity of selenium and its compounds in humans and animals (IARC 1975, Vol. 9).

Based on this evidence, OSHA preliminarily concludes that exposure to selenium and its compounds causes irritation of the eyes, skin, and mucous membranes, central nervous system effects, gastrointestinal disturbances, and liver and kidney effects. OSHA preliminarily finds that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that the proposed limit for selenium and compounds of 0.2 mg/m3 as an 8-hour TWA is necessary to significantly reduce these risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for these substances consistent across all regulated sectors.

SILVER, METAL AND SOLUBLE COMPOUNDS (as Ag) CAS: 7440-22-4; Chemical Formula: Ag (metal); varies (compounds)

H.S. No. 2143

In general industry, construction, and maritime, OSHA's permissible exposure limit for silver metal and the soluble silver compounds (measured as silver), is 0.01 mg/m3 as an 8-hour TWA. There is no limit in agriculture. The ACGIH has an 8-hour TLV*-TWA of 0.01 mg/m3 for these substances. NIOSH has no REL for these substances but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing to establish an 8-hour TWA limit of 0.01 mg/m³ for silver metal and the soluble silver compounds in agriculture. Promulgation of this limit will make the PEL for these substances consistent across all OSHA-regulated sectors.

Silver is a hard, brilliant white, lustrous, ductile metal. Silver nitrate is a colorless, odorless solid that may turn gray, and silver fluoride takes the form of a yellow to white, odorless solid. The principal soluble compounds of silver are silver nitrate, silver chloride, silver fluoride, and silver sulfide. Soluble silver compounds are used in photographic films, indelible inks, silver salts, medicines, and hair dyes and are also used to silver mirrors, plate silver. and catalyze ethylene oxide. These compounds are also used as pesticides. laboratory reagents, and as substitutes in organic compounds (Hawley's 1987, p. 1043; ACGIH 1986, p. 529). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

In humans, industrial exposure to the dust or fume of metallic silver or to the mists of soluble silver compounds is associated with the development of argyria, a bluish-grey discoloration of the eyes, mucous membranes, or skin; argyria is caused by the impregnation of the tissues with silver. In addition, several of the soluble silver compounds. such as silver nitrate, cause eye, nose, and upper respiratory tract irritation on acute exposure and kidney, liver, and lung damage on chronic exposure (Klaassen, Amdur, and Doull 1986, p. 625). The acute toxicity of all of the soluble silver compounds is high, regardless of the route of administration (Clayton and Clayton 1981, p. 1886). The oral LDso for silver nitrate in mice is 50 mg/kg; in guinea pigs, the oral LD50 for silver fluoride is 300 mg/kg (Clayton and Clayton 1981, p. 1886). Administered orally to experimental animals in repeated doses, metallic silver caused pigmentation of the eyes (Grant 1986, p. 815). Instilled into the eyes of rabbits, a 6-percent solution of silver nitrate caused scarring and a 12-percent solution caused blindness (HSDB 1989). Oral dosing with silver nitrate caused vascular hypertension in experimental animals; at autopsy, kidney changes were seen in these animals (HSDB 1989). Intravenous administration of silver nitrate caused hemolysis and death in animals of several species (HSDB 1989).

In humans, overexposure to the dust or fume of silver metal or to the soluble compounds of silver causes argyria, evidenced as a bluish-gray discoloration of the eyes, mucous membranes, or skin. Argyria may be either localized or systemic. Localized argyria is caused by the embedding of silver particles in the skin or by the absorption of silver salts through the sweat glands (Clayton and

Clayton 1981, p. 1887). If the dust, fume, or mist of the soluble compounds of silver is inhaled in sufficient quantities, argyria of the upper respiratory tract may occur. Two workers engaged in the manufacture of silver nitrate developed argyria of the respiratory tract, which was associated with mild chronic bronchitis (Browning 1969, pp. 296-301, in Proctor, Hughes, and Fischman 1988, p. 442). Generalized argyria is manifested as widespread pigmentation of the skin, eyes, and nails (Clayton and Clayton 1981, p. 1887-1888). A worker "massively" overexposed to the heated vapor of metallic silver for 4 hours subsequently developed pulmonary edema and lung damage (Forycki et al., Bull. Inst. Maritime Tropical Medicine in Gydnia 34:199-202, 1963). Twelve cases of argyria were reported in silver workers exposed to concentrations of 1 to 2 mg/m3 of silver during varnish spraying (Jindrichova 1963, in ACGIH 1986, p. 529). Eleven of these workers had upper respiratory tract argyrosis and nine showed argyria of the conjunctiva or cornea (Jindrichova 1963, in ACGIH 1986, p. 529). Four cases of eye and skin argyrosis also were reported in silver polishers (Perrone et al. 1977, in ACGIH 1986, p. 529).

Based on this evidence in humans and animals, OSHA preliminarily concludes that exposure to silver metal and the soluble silver compounds causes eye. skin, and mucous membrane irritation, as well as respiratory, gastrointestinal. central nervous system, liver, and kidney effects. OSHA therefore believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse exposurerelated effects. The Agency believes that the proposed TWA limit of 0.01 mg/m3 for silver and its soluble compounds (measured as silver) is necessary to substantially reduce the significant risk that workers in agriculture will experience these material health impairments. Promulgation of this limit will also make the PEL for silver and its soluble compounds consistent across all regulated sectors.

SODIUM FLUOROACETATE CAS: 62-74-8; Chemical Formula:

CH₂FCOONa H.S. No. 1366

In construction and maritime, the current OSHA standard for sodium fluoroacetate is 0.05 mg/m³ as an 8-hour TWA, with a skin notation. There is no limit in agriculture. The ACGIH has exposure limits of 0.05 mg/m³ TLV³—TWA and 0.15 mg/m³ TLV\$—STEL, with a skin notation. In construction and maritime, OSHA is retaining its 8-hour TWA PEL and skin notation and is

proposing to add a STEL of 0.15 mg/m³; the Agency is also proposing to extend these limits to agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limits being proposed, which were recently established for this substance in general industry.

Sodium fluoroacetate is a fine white powder, which is sometimes dyed black for commercial use. It is used as a rodenticide (ACGIH 1986, p. 534). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Sodium fluoroacetate causes vomiting, convulsions, and ventricular fibrillation. It is highly toxic by inhalation, ingestion, or via absorption through the skin (NIOSH/OSHA 1981). The ACGIH calculated and set the threshold limit of 0.05 mg/ma based on studies of rats indicating an oral LDso of 1.7 mg/kg (Lehman 1951/Ex. 1-790). Tissue changes in rats were noted in a later study by the same author in which the animals were fed 0.25 mg sodium fluoroacetate/kg/day (Lehman 1952, as cited in ACGIH 1986/Ex. 1-3, p. 534); the equivalent level in humans would be 17 mg/person/day. A further study by Miller and Phillips (1955, as cited in ACGIH 1986/Ex. 1-3, p. 534) examined growth rates in rats fed various dosages of sodium fluoroacetate. Rats who received 10 ppm in their diet experienced a transient fluctuation in growth rate. At 20 ppm (approximately 2 mg/kg in young rats), the growth rate declined markedly the first week; the rats survived and resumed growth at the normal rate in 3 to 4 weeks. Tolerance for the chemical lasted less than 2 weeks, and those rats who had adjusted to sodium fluoroacetate showed a second retardation of growth when returned to a dietary level of 20 ppm after a 2-week interval of eating a normal diet. Miller and Phillips (1955, as cited in ACGIH 1986/Ex. 1-3, p. 534) noted that rats conditioned to a dietary level of 20 ppm were then able to adjust to a level of 40 ppm (a dose that is greater than the single LD50 dose per day).

Based on this evidence, OSHA is retaining the 8-hour TWA limit of 0.05 mg/m³ and the skin notation and is proposing a STEL of 0.15 mg/m³ for sodium fluoroacetate in construction and maritime; the Agency is also proposing these limits in agriculture. OSHA preliminarily concludes that the 8-hour TWA and short-term exposure limits, with a skin notation, will reduce the risk of systemic effects posed to workers in these sectors who are

exposed to sodium fluoroacetate. OSHA considers these effects material health impairments. Promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

STRYCHNINE

CAS: 57-24-9; Chemical Formula:

C₂₁H₂₂N₂O₂ H.S. No. 2145

OSHA's PEL for strychnine in general industry, construction, and maritime is 0.15 mg/m³ as an 8-hour TWA. There is no limit in agriculture. The 1987–1988 ACGIH TLV®-TWA is also 0.15 mg/m³. NIOSH has no REL but concurs (Ex. 8–47, Table N3A) with the limit being proposed for strychnine. OSHA is proposing an 8-hour TWA of 0.15 mg/m³ for strychnine in agriculture. Promulgation of this limit would make OSHA's PEL for this substance consistent across all industry sectors.

Strychnine is an odorless, colorless or white crystalline solid (HSDB 1989). This substance is used to control rodents in agriculture and also finds limited use in medicine (ACGIH 1986, p. 538). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Strychnine is a powerful convulsant in both humans and animals. The oral LD₅₀ in rats is 2350 µg/kg, and the oral LD₅₀ in dogs is 500 µg/kg (RTECS 1990). Acutely poisoned animals develop severe convulsions and paralysis before death (RTECS 1990). Strychnine's stimulant properties act principally on the spinal cord, but the medullary centers of the brain are also involved

(Hayes 1982, p. 98).

Strychnine's effects on humans are similar to those in animals. The mean lethal dose in humans is estimated to lie between 100 and 120 mg (or 1.5 to 2 mg/ kg body weight). However, a total dose as small as 16 mg has killed an adult (Gosselin, Smith, and Hodge 1984, p. III-375). Doses of 5 to 7 mg cause muscle tightening and twitching; the neck, jaws, and little fingers are particularly affected (Hayes 1982, pp. 96-101). After ingestion, any stimulus (light, sound, touch) is likely to set off a violent convulsion (Franz 1985). As many as 10 to 15 convulsions may occur before death, although cardiac or respiratory arrest may occur between the second and third convulsions (Hayes 1982, pp.

Based on this evidence in humans and animals, OSHA preliminarily concludes that workers in agriculture are at significant risk of experiencing strychnine's convulsant effects in the absence of an OSHA PEL. Accordingly, OSHA is proposing a PEL of 0.15 mg/m³ as an 8-hour TWA for strychnine in agriculture. The Agency believes that this limit is necessary to substantially reduce the significant risk of these adverse health effects, which constitute material health impairments. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. TELLURIUM AND COMPOUNDS (as

CAS: 13494–80–9; Chemical Formula: Te H.S. No. 2150

In general industry, construction, and maritime, OSHA's permissible exposure limit for tellurium and its compounds (measured as tellurium) is 0.1 mg/m3 as an 8-hour TWA. There is no limit in agriculture. The ACGIH has an 8-hour TLV*-TWA of 0.1 mg/m3 for tellurium and its compounds. NIOSH has no REL for these substances but concurs (Ex. 8-47) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 0.1 mg/m³ for tellurium and compounds (measured as tellurium) in agriculture. Promulgation of this limit will make the PEL for these substances consistent across all OSHA-regulated sectors.

Tellurium is a non-metallic silverywhite lustrous solid. This substance is used as an additive for copper, iron, and steel, in the vulcanization of rubber, as a coloring agent in ceramics, and as an ingredient in thermoelectric devices and in storage batteries. Some telluride compounds are used as semiconductors (ACGIH 1986, p. 555; Hawley's 1987, p. 1124). Examples of tellurium compounds are hydrogen telluride, potassium tellurite, and sodium tellurate. (Tellurium hexafluoride has a separate

PEL.)

Tellurium causes garlic odor of the breath, central nervous system effects. and kidney and liver damage in humans; in animals, this substance causes neurotoxic and teratogenic effects. The oral LD50s for tellurium in rats, mice, rabbits, and guinea pigs are 83 mg/kg, 20 mg/kg, 67 mg/kg, and 45 mg/kg, respectively (RTECS 1990). Acute exposure to tellurium can cause restlessness, tremor, diminished reflexes, paralysis, convulsions, somnolence, coma, and death (Cooper 1971, in Proctor, Hughes, and Fischman 1988, p. 458). Inhalation of hydrogen telluride has produced pulmonary irritation and hemolysis of red blood cells in animals (AIHA Hygienic Guide Series 1964; Cerwenka and Cooper 1961, in Proctor, Hughes, and Fischman 1988, p. 458). A dietary concentration of 1500 ppm had only a slight effect on the growth in rats (DeMeio 1946, in ACGIH

1986, p. 555). Chronic tellurium poisoning (by subcutaneous or intramuscular injection) caused degenerative changes in the retinal ganglion cells and brain of cats after 3 months (Pentschew 1958, in HSDB 1989). Tellurium poisoning (route, dose, and duration not specified) caused encephalopathy and changes in the retinal ganglion cells, optic nerves, and optic tract (Grant 1986, p. 887). Given 3300 ppm in the diet for 5 months, rats showed a markedly impaired ability to learn sequential behavioral tasks (Dru et al. 1972, in HSDB 1989). Rats chronically exposed to high doses of tellurium dioxide had decreased growth and developed necrosis of the liver and kidney (Cerwenka and Cooper 1961; Browning 1969, in Klaassen, Amdur, and Doull 1986, p. 625). Pregnant rats fed 300 to 500 ppm tellurium had a high incidence of hydroencephalic offspring (Duckett 1970, in Proctor, Hughes, and Fischman 1988, p. 458). Pregnant rats and rabbits fed a diet containing 3000 or 15,000 ppm (rats) or 5250 ppm (rabbits) tellurium during pregnancy give birth to offspring with skeletal and soft-tissue malformations (Johnson, Christian, Hoberman, DeMurco, Kilpper, and Mermelstein 1989, in Fund. Appl. Toxicol. 11(4):691-702). Weanling rats fed 10,000 ppm tellurium developed segmental demyelination; however, remyelination occurred even after continued exposure to tellurium (Lampert, Garro, and Pentschew 1970, in Proctor, Hughes, and Fischman 1988, p. 458). Neonatal rats exposed to tellurium in mothers' milk from birth until sacrifice at 7, 14, 21, or 28 days of age showed Schwann cell and myelin degeneration in the sciatic nerves and hypomyelination of the optic nerves at autopsy (Jackson, Hammurg, Worth, and Duncan 1989, in Acta. Neuropathol. Berlin 78(3):301-309).

No serious cases of industrial poisoning caused by tellurium have been reported in humans. A garlic odor of the breath and sweat, dryness of the mouth, a metallic taste in the mouth, somnolence, anorexia, and nausea were reported among iron foundry workers exposed to tellurium concentrations between 0.01 and 0.1 mg/m³ for 22 months; somnolence and metallic taste did not occur until these workers' urinary tellurium levels were at least 0.01 mg/l (Steinberg, Massari, Miner, and Rink 1942; Cerwenka and Cooper 1961, in AIHA Hygienic Guide Series 1964). Mild neurologic effects have occurred in workers exposed to tellurium salts during industrial manufacturing processes (Klaassen, Amdur, and Doull 1986, p. 374). In workers in an electrolytic lead refinery.

exposure to tellurium dioxide resulted in skin lesions in the form of scaly, itching patches, and loss of sweat function (Browning 1969, in Proctor, Hughes, and Fischman 1988, p. 458). Accidental administration of about 2 gm of sodium tellurite caused death in two adults within 6 hours. The signs of toxicity were vomiting, renal pain, stupor, loss of consciousness, irregular breathing, and cyanosis; autopsy revealed fatty degeneration of the liver (Gosselin 1984, p. II–129).

Based on this evidence in humans and animals, OSHA preliminarily concludes that tellurium and its compounds impart a garlic odor to the breath and sweat and cause central nervous system effects, cardiac effects, and kidney and liver changes. OSHA preliminary finds that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. Accordingly, the Agency proposes to establish an 8-hour TWA limit of 0.1 mg/m3 for tellurium and its compounds in agriculture. OSHA believes that the proposed limit is necessary to substantially reduce these risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for these substances consistent across all regulated sectors.

TETRAETHYL LEAD (as Pb)
CAS: 78-00-2; Chemical Formula:
(C₂H₅)₄Pb

(C₂H₅)₄Pb H.S. No. 1386

OSHA's 8-hour TWA limit for tetraethyl lead (TEL) in construction and maritime is 0.1 mg/m3, measured as lead, with a skin notation. There is no limit in agriculture. The ACGIH recommends that worker exposures to TEL not exceed 0.1 mg/m3 TWA; the ACGIH also recommends a skin notation. NIOSH has no REL, but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour TWA limit of 0.075 mg/m3, and a skin notation, for tetraethyl lead in construction, maritime, and agriculture. This is the limit recently established for TEL in general industry.

Tetraethyl lead is a colorless liquid that may be dyed red, orange, or blue and that has a slightly musty odor. It is used as an anti-knock additive in gasoline (ACGIH 1986, p. 562).

Tetraethyl lead is a central nervous system toxin in humans and animals. The oral LD₅₀ in rats is 12.3 mg/kg, and the LC₅₀ in the same species is 850 mg/m³ for 1 hour (RTECS 1990). The lowest lethal dermal dose in rabbits is 830 mg/kg (RTECS 1990). Instilled into the eyes of rabbits, TEL caused redness, blepharospasm, and discharge, but these effects were reversible (Grant 1986, pp.

890-893). Acutely poisoned animals showed tremors, irritability, and spasticity after a single dose of approximately 17 mg/kg; repeated doses at one-tenth this level, however, caused behavioral changes, peripheral hyperemia, cardiac hypertrophy, brain edema, and changes in the liver, pancreas, thyroid, lung, and thymus (IARC 1973, Vol. 2, p. 156). Administered to rhesus monkeys orally (at a dose of 6 mg/kg/day) for 6 months, TEL caused no clinical manifestations of toxicity, although elevated blood and tissue levels of lead were seen in these animals (Heywood, R. et al. 1979, Toxicol Letter 4(2): 119-125). Carcinogenicity bioassays have been

negative.

In humans, TEL poisoning causes psychosis, convulsions, and if the exposure is sufficiently severe, death. More than 150 deaths have been attributed to TEL poisoning, although many of these have involved accidental or suicidal ingestion rather than occupational exposure. However, several workers have died while cleaning leaded gasoline storage tanks without proper personal protective equipment (Proctor, Hughes, and Fischman 1988, p. 461). TEL poisoning can occur after a single one-hour exposure to 100 mg/m3 or after repeated exposures to lower levels, and the signs and symptoms may be so subtle as to go undetected (Kehoe, in Parmeggiani 1983, pp. 1197-1199). The signs and symptoms of TEL poisoning include headache, fatigue, weakness, nausea, vomiting, diarrhea, and anorexia and may progress to ataxia, tremor, bradycardia. and hypothermia (Grandjean 1984). Chronic exposure to TEL causes cumulative liver, kidney, and central nervous system damage (Cralley and Cralley 1985, p. 182).

Based on this evidence in humans and animals, OSHA preliminarily concludes that workers in construction, maritime, and agriculture exposed to this substance are at significant risk of experiencing central nervous system damage as well as liver and kidney damage. The Agency believes that the proposed PEL of 0.075 mg/m3 is necessary to substantially reduce this significant risk. OSHA is therefore proposing a PEL of 0.075 mg/m3 as an 8hour TWA (measured as Pb), and a skin notation, for tetraethyl lead in construction, maritime, and agriculture. Promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. TETRAMETHYL LEAD (as Pb) CAS: 75-74-1; Chemical Formula:

(CH₃)₄Pb

H.S. No. 1388

The OSHA limit for tetramethyl lead (TML) in construction and maritime is 0.15 mg/m³ (measured as lead) as an 8-hour TWA, with a skin notation. The ACGIH has a TLV*-TWA of 0.15 mg/m³, with a skin notation, for this substance. There is no limit in agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour TWA of 0.075 mg/m³, with a skin notation, for this substance in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry.

Tetramethyl lead is a colorless liquid, which may be dyed blue, orange, or red in commercial use; it has a slight musty odor. It is used as an anti-knock additive in gasoline (ACGIH 1986, p. 565).

Tetramethyl lead is toxic to the central nervous system of humans and animals. The oral LD50 in rats is 90 mg/ kg, the LC50 in mice is 8500 mg/m3 for 30 minutes, and the lowest lethal dermal dose in rabbits is 3391 mg/kg (RTECS 1990). Acutely poisoned animals develop tremors, hyperexcitability, and convulsions before death (Schepers 1964). If inhaled, TML has only onetenth the toxicity of tetraethyl lead in rats; however, in dogs and mice, TML is more toxic than TEL (Cremer and Calloway 1961). Rats exposed repeatedly to 10.8 mg/kg developed behavioral changes and peripheral hyperemia; at autopsy, cardiac hypertrophy, hyperemia, and edema of the brain and lungs were seen (IARC 1973, Vol. 2, p. 157). Monkeys given 6 mg/kg/day intravenous doses of TML showed gastrointestinal disturbances, tremor, abnormal reflexes, and depressed brain cholinesterase levels (Heywood et al. 1978). Carcinogenicity bioassays with TML have been negative. No teratogenic effects were seen in the offspring of rats given 40, 80, 112, or 160 mg/kg TML by oral administration [McClain and Becker 1972, in IARC 1980, Vol. 23, p. 370).

In humans, several cases of acute toxicity have been reported; the signs and symptoms were indicative of encephalopathy (IARC 1973, Vol. 2, p. 158). In humans, TEL is believed to be three times as toxic as TML (IARC 1973, Vol. 2, p. 158). However, there are few data on the toxicity of TML in humans.

OSHA preliminarily concludes, based on this evidence in humans and animals, that workers in construction, maritime, and agriculture are at significant risk of experiencing lead poisoning in the form of encephalopathy. The Agency believes that the proposed PEL of 0.075 mg/m³ is

necessary to substantially reduce this risk among these workers. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors. TETRAMETHYL SUCCINONITRILE CAS: 3333-52-6; Chemical Formula:

C₈H₁₂N₂ H.S. No.: 2156

The OSHA limit for tetramethyl succinonitrile in general industry, construction, and maritime is 0.5 ppm as an 8-hour TWA, with a skin notation. The ACGIH TLV*-TWA is also 0.5 ppm as an 8-hour TWA, with a skin notation. NIOSH has a REL of 1 ppm as a 15-minute ceiling but concurs with the limit being proposed (Ex. 8-47, Table N3A). OSHA is proposing a PEL of 0.5 ppm as an 8-hour TWA, with a skin notation, in agriculture, an action that would make the PEL for this substance consistent across all OSHA-regulated workplaces.

Tetramethyl succinonitrile is a colorless and odorless solid. This substance is a decomposition product that is released when

azobisisobutyronitrile, a foam blowing agent, is heated (ACGIH 1986, p. 466).

Tetramethyl succinonitrile is a systemic toxin that produces convulsions in exposed humans and animals. The oral LD50 is 60 mg/kg (Sax and Lewis 1989, p. 3228). Rats exposed to a 60-ppm concentration of this substance for 2 or 3 hours died, as did rats exposed for 30 hours to a 6-ppm concentration (Oetel 1958, in ACGIH 1986, p. 566). Ingestion of a 25-mg/kg dose of tetramethyl succinonitrile also caused 100 percent mortality in rata (Oetel 1958). Rats, guinea pigs, rabbits, and dogs dosed with this substance by various routes of administration developed convulsions and subsequently died of asphyxiation (NIOSH Criteria Document (Nitriles) 1978, p. 155).

In a personal communication to the ACGIH's TLV* committee, Dr. Ernest Mastromattee reported that several workers at a vinyl foam plant in Ontario, Canada, reported experiencing headaches and nausea after exposure to tetramethyl succinonitrile (ACGIH 1986, p. 566). There are reports of similar symptoms, and of convulsions and comas, in European workers exposed to unspecified concentrations of tetramethyl succinonitrile (Reinl 1957; Quoss 1959, both cited in ACGIH 1986, p. 566). No other toxicity information has been reported for this substance.

Based on this evidence in humans and animals, OSHA preliminarily concludes that tetramethyl succinonitrile is a systemic poison that potentially causes headache, nausea, and convulsions in exposed workers. Accordingly, the Agency is proposing a PEL of 0.5 ppm as an 8-hour TWA, with a skin notation, for this substance in agriculture. OSHA believes that this action will substantially reduce these risks of material health impairment among agricultural workers. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. TETRYL (2.4.6-

Trinitrophenylmethylnitramine)
CAS: 479-45-8; Chemical Formula:
C7H₅N₅O₈

H.S. No. 2158

OSHA's current limit for tetryl in construction, maritime, and general industry is 1.5 mg/m3 as an 8-hour TWA, with a skin notation. There is no limit in agriculture, and NIOSH has no REL for this substance but concurs (Ex. 8-47, Table N3A) with the limit being proposed. The ACGIH TLV®-TWA is 1.5 mg/m3, with a skin notation, for this substance. OSHA is proposing an 8-hour TWA PEL of 1.5 mg/m3, with a skin notation, for tetryl in agriculture; adoption of this limit would make OSHA's PEL for this substance consistent across all OSHA-regulated industry sectors. Tetryl (2,4,6-

Tetryl (2,4,6trinitrophenylmethylnitramine) is used
as a booster explosive, a component in
binary explosives, a primer for other
explosives, and as a chemical indicator
in the laboratory (HSDB 1988). Tetryl is
a colorless to yellow crystalline solid
with a bitter taste and no odor (ACGIH

1986, p. 568.1(88)).

Tetryl is an irritant and sensitizer of the skin and respiratory tract; exposure to tetryl has also been associated with systemic poisoning in the form of blood changes and liver toxicity. Little acute toxicity information is available. The lowest lethal dose of tetryl in dogs by subcutaneous administration is 5000 mg/kg (RTECS 1990). Rabbits given 1-g/kg doses of tetryl by stomach tube died after no more than three doses; at autopsy, degeneration of the kidneys was seen in these animals (Wells, Lewis, Sansum et al. 1920, in ACGIH 1986, p. 568.3(88)).

In humans, exposure to tetryl dust has caused eye, skin, and respiratory irritation; skin and pulmonary sensitization; liver damage; and anemia. Tetryl dust also stains the hair and skin of exposed workers yellow. Workers exposed to concentrations of tetryl below 1.5 mg/m³ for 10 years did not show signs of systemic toxicity but did report gastrointestinal and respiratory symptoms and skin sensitization (Bergman 1952). The dermal

sensitization effects in these workers progressed from itching of the skin and eyes to erythema and edema (Bergman 1952). Eleven workers accidentally overexposed to tetryl developed yellow pigmentation of the skin, dermatitis. sensitization, respiratory tract irritation, and clinical signs of liver damage; two of these workers died and one became disabled (Hardy and Maloof 1950). Several of the surviving workers were subsequently forced to leave employment because of respiratory sensitization (Hardy and Maloof 1950). A study of a group of 1,258 tetrylexposed workers revealed dermatitis and clinical evidence of secondary anemia in many of these workers. The symptoms of systemic illness reported by workers in this group include headache, lassitude, sleeplessness, and irritability (Hardy and Maloof 1950). In workers severely overexposed, irreversible liver damage has also occurred (Hardy and Maloof 1950).

Based on this evidence in humans and animals, OSHA preliminarily concludes that an 8-hour TWA limit of 1.5 mg/m³, and a skin notation, is necessary to protect agricultural workers from the skin and respiratory tract irritation and sensitization, blood effects, and liver damage potentially associated with exposure to tetryl. The Agency believes that the proposed limit will substantially reduce these significant risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

THIRAM

CAS: 137–26–8; Chemical Formula: C₆H₁₂N₂S₄
H.S. No. 2160

OSHA's limit for thiram in general industry, construction, and maritime is 5 mg/m³ as an 8-hour TWA. There is no limit in agriculture. The ACGIH TLV®—TWA for this substance is 5 mg/m³ as an 8-hour TWA. NIOSH has no REL for this substance but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 5 mg/m³ for thiram in agriculture, which would make OSHA's PEL for this substance consistent across all industry sectors.

Thiram is a white or pale yellow powder with a characteristic odor. Thiram is used in many products and processes, including the compounding of natural and synthetic rubbers, the production of fungicides, in animal repellents, as a bacteriostat in soaps, and as an ingredient in antiseptic sprays (IARC 1976, Vol. 12, p. 228). Thiram is the methyl analog of Antabuse® (disulfiram), the drug used to control

alcoholism by interfering with the metabolism of alcohol (Clayton and Clayton 1981, p. 2104). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Thiram is an irritant of the eyes, mucous membranes, and skin; a skin sensitizer; and a metabolic poison. This substance is also a teratogen in experimental animals. The oral LD50 in rats is 560 mg/kg, and the lowest lethal dermal dose in rabbits is 1 g/kg (RTECS 1990). Acutely poisoned animals show hyperemia and focal ulceration of the gastrointestinal tract, necrosis of the liver and kidney, and demyelinization of the cerebellum and medulla (Child and Cramp 1952, in Gosselin, Smith, and Hodge 1984, p. III-383). Before death, acutely poisoned animals lose coordination, develop tremors and difficult breathing, and convulse (Ben-Dyke, Sunderson, and Ninakes 1970, in ACGIH 1986, p. 573.3(87)). In contact with the skin or eyes of rabbits, thiram causes irritation, and repeated contact of this substance with the skin of rabbits and guinea pigs has caused dermal sensitization (RTECS 1990; Griepentrop 1960; Brusilovsky and Fialikovsky 1973, in ACGIH 1986, p. 573.3(87)). Rats fed 100, 300, or 500 mg/kg thiram for 2 years showed reductions in growth rate; at the highest dose, the rats convulsed and, at autopsy, had thyroid hyperplasia and calcification of the brain (IARC 1976, Vol. 12, p. 231). Administered to rats, mice, and hamsters by the oral and/or subcutaneous route, thiram caused teratogenic effects in the offspring (RTECS 1990).

Ingestion of alcohol and concomitant exposure to thiram causes the signs and symptoms of systemic Antabuse*alcohol syndrome: Flushing of the skin, palpitations, headache, nausea, vomiting, and difficult breathing (Hayes 1982, pp. 603-606). One worker died after treating seeds with thiram over a 10-hour period; it is not known whether this worker also ingested alcohol (Hayes 1982, pp. 603-606). Workers chronically exposed to low levels of thiram may develop facial flushing after they ingest alcohol, and thiram can produce dermatitis and sensitization in some workers even in the absence of alcohol ingestion (Shelley 1964). A study of 223 workers exposed to thiram for more than 3 years revealed an increased incidence of eye irritation, chest pain, tachycardia, nose bleeds, skin lesions, liver dysfunction, myocardiodystrophia, and asthenia in these workers compared with the incidence for a group of nonthiram-exposed workers. The thiramexposed group also showed an excess incidence of enlarged thyroid and other thyroid abnormalities, as well as one case of thyroid adenocarcinoma (Cherpak et al. 1971; Kaskevich and Bezugly 1973, in IARC 1976, Vol. 12, p. 232).

Based on this evidence in humans and animals, OSHA preliminarily concludes that thiram poses a potentially significant risk of systemic toxicity to agricultural workers. The Agency believes that the proposed 5 mg/m³ 8-hour TWA PEL is necessary to substantially reduce this risk of material health impairment among these workers. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

TIN, METAL AND INORGANIC COMPOUNDS (as Sn) CAS: 7440-31-5; Chemical Formula: Sn H.S. No. 2161

OSHA's permissible exposure limit for tin and its inorganic compounds (measured as tin) in general industry, construction, and maritime is 2 mg/m³ as an 8-hour TWA. There is no limit in agriculture. The ACGIH has an 8-hour TLV*-TWA of 2 mg/m³ for these substances, and NIOSH has no REL. OSHA is proposing an 8-hour TWA limit of 2 mg/m³ for tin and inorganic tin compounds (measured as tin) in agriculture. Promulgation of this limit will make the PEL for these substances consistent across all OSHA-regulated sectors.

Tin is an odorless, soft, white, silvery metal. Among its inorganic compounds are stannous chloride, an odorless, colorless to brown solid; stannic chloride, which is a colorless to yellow fuming liquid with an acrid odor; and stannous sulfate, a colorless to brown, odorless solid. Tin and its inorganic compounds are used in tin plating, solder and alloy production, and in the manufacture of toothpaste, ceramics, drill-glass, porcelain, enamels, textiles, and ink (Rom 1983, p. 501; NIOSH/OSHA Occupational Health Guideline 1981, p. 1).

Exposure to metallic tin dust or to inorganic tin compounds causes eye, nose, skin, and respiratory tract irritation, gastrointestinal effects, and anemia in humans and animals. The oral LD50 values for tin sulfate in rats and mice are 2207 mg/kg and 2152 mg/kg, respectively (RTECS 1990). In rats, mice, and rabbits, the oral LD50 for stannous chloride are 700 mg/kg, 250 mg/kg, and 10 g/kg, respectively (RTECS 1990). Tin tetrachloride has an LC50 in rats of 2300 mg/m³ for 10 minutes (RTECS 1990). The

intraperitoneal injection of tin dust resulted in a non-specific, vascularized chronic granulomatous reaction in guinea pigs (Oyanguren, Haddad, and Maass 1958, in ACGIH 1986, p. 574). The soluble acid salts of tin produce dermal effects in rabbits, including intraepidermal polymorphonuclear leukocyte pustules when large amounts are held in contact with the skin for 18 hours; the application of lower concentrations causes polymorphonuclear infiltrates (Stone and Willis; Connie et al. 1975 and 1976; Yum et al. 1976, in Clayton and Clayton 1981, p. 1946). The signs and symptoms of low-level subacute tin toxicity are diarrhea, paralysis, twitching, hyperemia, and vascular changes, which in turn cause internal bleeding and death (Barnes and Stoner 1959, in Clayton and Clayton 1981, p. 1946). Rats fed tin oxides and various tin salts for 4 or 13 weeks at levels of 0.03, 0.1, 0.3, or 1.0 percent showed signs of growth retardation, decreased food efficiency, slight anemia, and liver changes at the 0.3 percent level or higher; the no-effect level was estimated to be 0.1 percent or 22 to 23 mg/day (deGroot et al. 1973, in Clayton and Clayton 1981, p. 1946) Paralysis was produced in dogs after daily administration of stannous chloride in milk at a level of 500 mg/kg for 14 months (Stauden 1972, in Proctor, Hughes, and Fischman 1988, p. 475).

In humans, some inorganic tin compounds cause skin and eye irritation because of an acid or alkaline reaction produced when the compound reacts with water (Stauden 1972, in Proctor, Hughes, and Fischman 1988, p. 475). Stannic chloride is highly irritating to the eyes and mucous membranes (Grant 1986, p. 846). Workers involved in glass bottle production who were exposed to a stannic chloride mist in concentrations of 0.10 to 0.18 mg/m3 and to hydrogen chloride at a concentration of 5 ppm experienced an excess of respiratory irritation when compared to workers exposed predominantly to hydrogen chloride (Levy, Davis, and Johnson 1985, in Proctor, Hughes, and Fischman 1988, p. 475). Because of low absorption and rapid tissue turnover, the ingestion of inorganic tin causes only moderate toxicity. The ingestion of food contaminated with tin compounds at levels greater than 1400 ppm causes symptoms of gastrointestinal irritation such as nausea, abdominal cramps, vomiting, and diarrhea (Schafer and Femfurt 1984, in Proctor, Hughes, and Fischman 1988, p. 475). Chronic absorption of low levels of tin has caused abdominal pain, nausea, constipation, weight loss, sore throat,

mild fever, a sensation of being chilled, myalgias, arthralgias, and moderate

anemia (HSDB 1986).

Based on this evidence, OSHA preliminarily concludes that tin and its inorganic compounds cause primary irritation, gastrointestinal effects, and anemia. OSHA therefore believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that the proposed limit of 2 mg/m3 as an 8-hour TWA is necessary to substantially reduce the risks of these material health impairments. Promulgation of this limit also will make the PEL for tin and its inorganic compounds consistent across all OSHA-regulated sectors.

TRIMETHYLBENZENE
CAS: 25551-13-7; Chemical Formula:
(CH₉)₂C₆H₅
H.S. No. 1412

OSHA currently has an exposure limit of 25 ppm as an 8-hour TWA for trimethylbenzene in general industry, construction, and maritime. There is no limit in agriculture. The ACGIH TLV^e for all isomers of trimethylbenzene is 25 ppm as an 8-hour TWA. OSHA proposes a PEL of 25 ppm as an 8-hour TWA in agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the 25-ppm TWA limit being proposed. This action would make OSHA's PEL for trimethylbenzene consistent across all regulated sectors.

Trimethylbenzene is a liquid mixture of three isomers. The isomers are used as raw materials for chemical synthesis and in ultra-violet stabilizers (ACGIH 1986, p. 508). Trimethylbenzene also is

used in solvents.

A study by Battig, Grandjean, and Turrian (1957/Ex. 1-104) provides the basis for the proposed limit; this work reports symptoms among 27 workers exposed to a solvent containing 30 percent 1,3,5-trimethylbenzene and 50 percent 1,2,3-trimethylbenzene. A 'significant number" of these workers were reported to have experienced symptoms of nervousness, tension and anxiety, and asthmatic bronchitis. The peripheral blood of these workers "showed a tendency to hypochromic anemia" and a somewhat abnormal clotting ability. This group of workers had been occupationally exposed to total hydrocarbon concentrations ranging from 10 to 60 ppm for several years. The authors of the study recommended maintaining employee exposures below 35 ppm (Battig. Grandjean, and Turrian 1957/Ex. 1-104).

Based on this evidence, OSHA is proposing a 25-ppm 8-hour TWA PEL for trimethylbenzene in agriculture to reduce the significant risks of bronchitis and blood effects reported to occur in exposed workers. The Agency considers these effects material health impairments and believes that the proposed PEL is necessary to substantially reduce these risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. TUNGSTEN, INSOLUBLE

COMPOUNDS (as W) CAS: 7440-33-7; Chemical Formula: W H.S. No. 1416

OSHA's PEL for tungsten and its insoluble compounds is an 8-hour TWA of 5 mg/m3 (measured as tungsten) in construction and maritime. There is no limit in agriculture. The ACGIH has established 5 mg/m3 as an 8-hour TLV®-TWA and 10 mg/m3 as a 15-minute TLV®-STEL for these substances. NIOSH recommends a limit of 5 mg/m3 as a 10-hour TWA. In construction and maritime, OSHA is retaining the PEL of 5 mg/m3 as an 8-hour TWA and is proposing a 15-minute STEL of 10 mg/ m3; the Agency is also proposing to extend these limits in agriculture. NIOSH concurs (Ex. 8-47, Table N1) with OSHA's proposed limits, which are the limits recently established for these substances in general industry.

Tungsten is a gray, hard metal.

Metallic tungsten is used in ferrous and non-ferrous alloys, incandescent lamps, heating elements, welding electrodes, rocket nozzles, and in solar energy equipment. Tungsten compounds are used in cemented carbide tools, dies and wear-resistant parts, textiles, ceramics, and plastics. Tungsten compounds are also used as solid lubricants and as abrasives (ACGIH 1986, p. 614).

Rats fed a diet containing 0.5 percent insoluble tungsten compounds died, and another group of rats fed 0.1 percent of these compounds suffered noticeable weight loss (Kinard and Van de Erve 1941/Ex. 1-492). Studies in rats fed tungsten at 2, 5, or 10 percent of their diet showed that females in all dose groups had a 15-percent reduction in weight gain (Kinard and Van de Erve 1943/Ex. 1-493). The intraperitoneal LD₅₀ for tungsten metal powder in rats was 5 g/kg body weight; survivors showed minor liver and spleen changes at necropsy (Fredrick and Bradley 1946, as cited in ACGIH 1986/Ex. 1-3, p. 614). Studies of the tissues of guinea pigs intratracheally injected with tungsten metal or with tungsten carbide revealed moderate interstitial cellular proliferation (tungsten metal) and no changes (tungsten carbide). However, Soviet studies involving similar intratracheal injections showed

proliferation of the intra-alveolar septa (Kaplun and Mezentseva 1960, as cited in ACGIH 1986/Ex. 1-3, p. 614).

The NIOSH criteria document for tungsten (1977h) reports that Russian investigators found a 9- to 11-percent incidence of pulmonary fibrosis in workers exposed to tungsten (Kaplun and Mezentseva 1959/Ex. 1-981; and Mezentseva 1967, as cited in ACGIH 1986/Ex. 1-3, p. 614). NIOSH (1977h) recommended that the standard for tungsten and its insoluble compounds be set at 5 mg/m3 to protect against pulmonary effects. Stokinger (Clayton and Clayton 1981) reported on several epidemiological studies of workers in the "hard metal industry," in which tungsten carbide is machined. These studies describe a condition known as hard metal disease, which may be accompanied by pulmonary fibrosis. The disease is characterized by a moderate incidence of cough, dyspnea, and wheezing, a high incidence of minor radiological abnormalities with a few instances of marked abnormalities, and development of hypersensitivity asthma in some workers (which may be due to exposure to the cobalt that is used as a binding agent). The disease is progressive and potentially lethal. This author (Clayton and Clayton 1981, p. 1992) reported that, unlike other lung diseases produced by inorganic dust, there is no correlation between onset of symptoms, length of exposure, and the development of interstitial fibrosis. Analysis of the lung of one worker who had clinical signs and radiological changes showed the presence of large amounts of tungsten with much smaller amounts of other metals.

In construction and maritime, OSHA is retaining the 8-hour TWA limit of 5 mg/m3 and proposing to add a STEL of 10 mg/m3 for tungsten and its insoluble compounds, measured as tungsten; the Agency is also proposing to extend these limits to agriculture. OSHA preliminarily concludes that these limits are necessary to substantially reduce the significant risk of pulmonary fibrosis and other lung effects, which OSHA considers material impairments of health. In addition, promulgation of these limits will make OSHA's PELs for these substances consistent across all regulated sectors.

TUNGSTEN, SOLUBLE COMPOUNDS (as W) CAS: 7440-33-7; Chemical Formula: W H.S. No. 1417

Currently, OSHA has a limit for tungsten and its soluble compounds in construction and maritime of 1 mg/m³ (measured as tungsten) as an 8-hour

TWA. There is no limit in agriculture. The ACGIH TLV®-TWA is 1 mg/m3, with a TLV*-STEL of 3 mg/m3. measured as tungsten. NIOSH recommends a 1-mg/m3 10-hour TWA for tungsten and its soluble compounds. OSHA is retaining the 8-hour TWA PEL of 1 mg/m3 and proposing to add a 15minute STEL of 3 mg/m3 for tungsten and its soluble compounds in construction and maritime; the Agency also proposes these limits in agriculture. NIOSH concurs (Ex. 8-47, Table N1) with the addition of a STEL to the 1-mg/ m3 TWA limit. These are the limits recently established for these substances in general industry.

Tungsten is a gray, hard metal.

Metallic tungsten is used in ferrous and non-ferrous alloys, incandescent lamps, heating elements, welding electrodes, rocket nozzles, and in solar energy equipment. Tungsten compounds are used in cemented carbide tools, dies and wear-resistant parts, textiles, ceramics, and plastics. Tungsten compounds are also used as solid lubricants and as abrasives (ACGIH 1986, p. 614).

Animal studies have shown that the LD50 for soluble sodium tungstate when injected subcutaneously in rats ranges from 140 to 160 mg/kg (Kinard and Van de Erve 1940/Ex. 1-788). Soluble tungsten's lethal effects are the result of systemic poisoning that occurs as the compound is absorbed by multiple organs; this is followed by cellular asphyxiation (International Labour Office [ILO] 1934c, as cited in ACGIH 1986/Ex. 1-3, p. 614). Karantassis (1924, as cited in ACGIH 1986/Ex. 1-3, p. 614) also observed a systemic response in guinea pigs given soluble sodium tungstate or pure soluble tungsten either orally or intravenously; the animals developed anorexia, colic, trembling, and difficulty in breathing prior to death. Rats fed a diet containing 0.5 percent tungsten as soluble sodium tungstate or tungsten oxide died from this dose. Dietary doses of 0.1 percent tungsten oxide and the sodium salt caused weight loss in rats, but no deaths (Kinard and Van de Erve 1941/Ex. 1-492). Tungsten is believed to act by antagonizing the action of molybdenum (Higgins, Richert, and Westerfield 1958/ Ex. 1-487). In its criteria document for tungsten, NIOSH (1977h) states that information on the effects of exposure to soluble tungsten compounds in the working population is not available.

OSHA is retaining the 8-hour TWA limit of 1 mg/m³ and proposing to add a STEL of 3 mg/m³ for tungsten and its soluble compounds, measured as tungsten, in construction and maritime; the Agency is also proposing to extend

these limits to agriculture. OSHA preliminarily concludes that these limits will protect workers in these sectors against the significant risks of systemic toxicity, anorexia, colic, incoordination, trembling, and dyspnea, all of which constitute material health impairments that are associated with exposure to these compounds. In addition, promulgation of these limits will make OSHA's PELs for these substances consistent across all regulated sectors.

VINYLIDENE CHLORIDE (1,1-DICHLOROETHYLENE) CAS: 75-35-4; Chemical Formula: CH₂ = CCl₂ H.S. No. 1428

OSHA has no limit for vinylidene chloride (VDC) in construction, maritime, or agriculture. The ACGIH has established a 5 ppm TLV*-TWA and a 20 ppm 15-minute TLV*-STEL. In 1978, NIOSH recommended that employee exposure to VDC be reduced to the lowest feasible level on the basis of VDC's carcinogenicity (Ex. 1-1119). OSHA is proposing a PEL of 1 ppm (8-hour TWA) for VDC in construction, maritime, and agriculture. This is the

Vinylidene chloride, also called 1,1dichloroethylene, is a colorless liquid that polymerizes readily. It is used primarily for production of vinylidene copolymers such as Saran® and Velon®. It is also used in films and coatings (ACGIH 1986, p. 628).

limit recently established for this

substance in general industry.

In animals, exposure to vinvlidene chloride causes irritation, kidney and liver damage, and cancer. The oral LDso in male rats is 2500 mg/kg (Jenkins, Trabulus, and Murphy 1972/Ex. 1-960). The LC50 for rats exposed to a single 4hour exposure of VDC vapor was reported as 6350 ppm in one study (Siegel, Jones, Coon, and Lyon 1971/Ex. 1-371) and 32,000 ppm in an earlier study (Carpenter, Smyth, and Pozzani 1949/Ex. 1-722). Liquid VDC causes transient irritation of the eyes in rats but has little effect on exposed skin if the VDC is allowed to evaporate (Torkelson and Rowe 1981b, as cited in ACGIH 1986/Ex. 1-3, p. 628). Prendergast and co-workers (1967/Ex. 1-926) exposed rats, rabbits, guinea pigs, and monkeys 8 hours/day, 5 days/week for 8 weeks to 395 mg/m3 (100 ppm); these authors saw no visible signs of toxicity while the exposure was in process, but rabbits and monkeys lost weight. Animals of these same species were exposed continuously to VDC concentrations of 5, 15, 25, or 47 ppm for 90 days; only the animals exposed to 5 ppm showed no increases in mortality (Prendergast,

Jones, Jenkins, and Siegel 1967/Ex. 1-926).

Nasal irritation, liver cell degeneration, and retarded weight gain were reported in rats following 20 8-hour exposures to 500 ppm VDC (Gage 1970/ Ex. 1-318); at 200 ppm, only nasal irritation occurred. Studies by Torkelson and Rowe (1981b, as cited in ACGIH 1986/Ex. 1-3, p. 628) in which rats. rabbits, guinea pigs, and dogs were exposed to 25, 50, or 100 ppm VDC for 8 hours per day, 5 days per week for 6 months revealed injury of the kidneys and liver in all animals at all levels of exposure. Maltoni (1977/Ex. 1-985) and Maltoni, Cotti, Morisi, and Chieco (1977/ Ex. 1-1090) conducted an evaluation of VCD's carcinogenicity in which mice, rats, and hamsters were exposed to levels from 10 to 150 ppm for 4 hours per day, 5 days per week for 52 weeks, with results reported through week 98 of the study. In those mice exposed to 25 ppm VCD, 21 percent of the males and 1.5 percent of the females developed kidney adenocarcinomas; these tumors were not seen in rats exposed to amounts of VDC up to 150 ppm. Exposures of 100 or 150 ppm in rats did produce a significant increase in mammary adenocarcinomas. and this response was dose-related (Maltoni 1977/Ex. 1-985; Maltoni, Cotti, Morisi, and Chieco 1977/Ex. 1-1090). Overt toxicity and mortality occurred early in the studies after 4-hour exposures at levels of 50 ppm in mice and 200 ppm in rats; hamsters exposed to 20 ppm VDC showed no increase in tumor incidence (Maltoni 1977/Ex. 1-985; Maltoni, Cotti, Morisi, and Chieco 1977/Ex. 1-1090).

Two strains of rats exposed to 75 or 100 ppm VDC for 5 days/week, 6 hours/ day for 12 months did not show a significant increase in tumors (Viola and Caputo 1977/Ex. 1-937). Other investigators exposed rats to 25 or 75 ppm by inhalation for 6 hours/day, 5 days/week for 18 months, or to 60, 100. or 200 ppm VDC in their drinking water for 2 years, and found no increase in tumor incidence in these animals (Rampy, Quast, Humiston et al. 1977, as cited in ACGIH 1986/Ex. 1-3, p. 628). In mice, VDC was not active either as a whole mouse skin carcinogen or by subcutaneous injection.

In an NTP gavage study of VDC in mice and rats (NTP 1982/Ex. 134B), the only observed significant increase in tumor incidence occurred in low-dose female mice; this increase was not considered to be related to VDC administration because similar effects were not observed in high-dose female mice, male mice, or rats. The NTP (1982/Ex. 134B) concluded that VDC was not

carcinogenic in mice or rats exposed by gavage, but cautioned that a maximum tolerated dose had not been demonstrated and that previously reported studies had shown that carcinogenicity is associated with VDC

inhalation by animals.

In other studies, VDC proved mutagenic in both E. coli and S. typhimurium strains (Greim, Bonse, Radwan et al. 1975/Ex. 1-904; Bartsch, Malaveille, Montesano, and Tomatis 1975/Ex. 1-889). VDC has been implicated as a tumor initiator in a carcinogenesis bioassay by Van Duuren, Goldschmidt, Loewengart et al. (1979/ Ex. 1-936). Studies by Reitz, Watanabe, McKenna et al. (1980/Ex. 1-927) suggest that VCD's tumorigenicity is a result of its ability to initiate cell injury, rather than of its ability to alter the genetic material of an injured cell. However, VDC has been shown to alkylate DNA in situ and to increase the rate of DNA repair to a small extent in mice (Norris and Reitz 1984/Ex. 134B). The actual cell injury is caused by VDC metabolites, which are highly reactive and cytotoxic (Maltoni 1977/Ex. 1-985; Hathway 1977/ Ex. 1-906; Henschler and Bonse 1977/Ex. 1-908).

A study by Murray, Nitschke, Rampy, and Schwetz (1979/Ex. 1-920) investigated the embryotoxic, fetotoxic, and teratogenic effects of inhaled and ingested VDC (in rats) and inhaled VDC (in rabbits). In the inhalation studies. rats were exposed to 20, 80, or 160 ppm VDC for 7 hours per day. VDC was toxic to both the adults and their embryos at levels of 80 and 160 ppm among the rats, and at 160 ppm in rabbits. At exposure levels of 20 ppm in rats and 80 ppm in rabbits, neither maternal toxicity nor effects on embryonic or fetal development were noted. In the ingestion study with rats, drinking water containing 200 ppm VDC caused no toxic effects in either the rats or their

ouspring.

A cohort study of 138 VCD-exposed workers did not identify any VCD-related health effects in these workers (Ott, Fishbeck, Townsend, and Schneider 1976/Ex. 1–924). The cohort was too small to provide any evidence that VDC is not likely to be

carcinogenic.

OSHA believes that these studies clearly demonstrate that VDC can cause adverse liver and kidney damage in animals at airborne concentrations as low as 25 to 50 ppm and suggest that VDC is a potential occupational carcinogen. Liver and kidney damage and cancer clearly constitute material health impairments within the meaning of the Act. Therefore, OSHA preliminarily concludes that a 1-ppm 8-

hour TWA limit for vinylidene chloride is necessary to protect workers in construction, maritime, and agriculture from these significant risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. WELDING FUMES (TOTAL

PARTICULATE) CAS: None; Chemical Formula: Varies H.S. No. 1430

In construction, maritime, and agriculture, OSHA has no limit for welding fumes, which are defined as fumes that are generated by the manual metal arc or oxy-acetylene welding of iron, mild steel, or aluminum. NIOSH has no REL for welding fumes. The ACGIH has set an 8-hour TLV®-TWA of 5 mg/m3 for these welding fumes, measured as total particulate in the welder's breathing zone. OSHA is proposing an 8-hour TWA limit of 5 mg/ m3 for these fumes in construction, maritime, and agriculture. This is the limit recently established for these fumes in general industry. This limit applies to the total fume concentration generated during the welding of iron, mild steel, or aluminum; the fumes generated by the welding of stainless steel, cadmium, or lead-coated steel, or other metals such as copper, nickel, or chrome are considerably more toxic and should be kept at or below the levels required by their respective PELs. Welding fumes consist of metallic oxides generated by the heating of metal being welded, the welding rod, or its

oatings.

Although these types of welding generally produce fumes consisting of aluminum, iron, or zinc oxides, other toxic gases may also be produced in large amounts (Ferry and Ginther 1952/ Ex. 1-900; Ferry 1954/Ex. 1-782; Silverman 1956/Ex. 1-1169; Homer and Mohr 1957/Ex. 1-787). The welding of iron metals may give off fumes of manganese, silicate, and various organic binders. Aluminum welding may generate fumes consisting of fluorine, arsenic, copper, silicon, and beryllium (NIOSH 1975h and American Welding Society 1974, both as cited in ACGIH 1986/Ex. 1-3, p. 634). Eighteen different substances, including fluoride, manganese, silicon, titanium, and sodium and potassium silicates, have been measured in the fumes resulting from the welding of mild steel (ACGIH 1986/Ex. 1-3, p. 634). Moreover, there are numerous and undefined additional compounds present in welding fumes whose health effects have not been fully assessed. These include naphthalene, phenol, cresol, dioxane, benzene, pyridine, and aromatic hydrocarbons.

Because these unregulated compounds may present additional, unidentified risks, OSHA reasonably determined that exposure to welding fumes is likely to cause adverse health effects at concentrations above 5 mg/m³.

Excessive exposure to welding fumes can cause a variety of disorders, most notably metal fume fever. It has been estimated that 30 to 40 percent of all welders have experienced metal fume fever at some time (Ross 1974, J. Occup. Med. 24:125, 127). This disorder, which results from exposure to freshly formed metal fume, results in the appearance of delayed, flu-like symptoms, including dyspnea, coughing, pains in muscles and joints, fever, and chills. Recovery usually requires 1 or 2 days of time away from work. In addition to fume fever, exposure to welding fumes may damage the small airways, causing interstitial pneumonia (Ross 1974). The recent NIOSH Criteria Document (1988) on welding fumes reviews the literature on the health effects of exposure to these fumes. Studies such as those by Ross (1974) and Antti-Poika demonstrate that workers exposed to these fumes at approximately 5 mg/m3 develop welding fume fever, chronic bronchitis, and other respiratory diseases. NIOSH (1988) reported that welders experience excess morbidity and mortality even when they are exposed to welding fumes at concentrations below the limits for many of the individual constituents of the welding emissions (Ex. 8-47, p. iii).

In the prior rulemaking, several commenters asked OSHA to clarify whether the limit applied to exposure samples taken inside or outside of the welding helmet. OSHA responded that it is current Agency policy that welding fumes are to be measured in the breathing zone (inside the welding hood) of the welder as stated in the 1990 Field

Operations Manual.

In the earlier rulemaking, NIOSH (Ex. 8–47) stated that welding fumes should be designated as a carcinogen; this view was shared by Dr. James Melius, of the New York State Department of Health (Tr. p. 11–104). In response to these commenters, OSHA states that more information and analysis are needed before this issue can be resolved. Accordingly, OSHA believes that it would be premature to identify these fumes as carcinogens.

OSHA intends that the proposed limit apply to all welding operations where the worker stands at or near the point where the welding takes place. This would include manual, some automatic welding where the rod is fed automatically, and other types of welding where the worker is located at

or near the point of the welding. The reason for OSHA's position is that coverage is needed where there is worker exposure—no matter what the name given to the welding. Fully automatic welding, in which the worker is located away from the welding operation and would have no exposure, is not covered by this limit. For several reaons, this limit is needed in addition to the limits for specific constituents of the welding fume. First, significant risk of material health impairment is associated with this type of welding. Second, individual substance limits have not proven sufficiently protective. Third, so many types of fumes are given off that an overall limit is necessary to help reduce possible synergistic effects. Fourth, for small-business employers and OHSA inspectors, measuring for overall welding fumes is easier and will thus encourage compliance. [However, OSHA PELs for the individual constituents of the fume-e.g., cadmium, lead, other metals-do remain in effect as applicable.)

OSHA preliminarily concludes that a PEL for welding fumes is needed to protect workers in construction, maritime, and agriculture who are involved in the welding of aluminum, iron, or mild steel from the significant risk of metal fume fever and respiratory irritation associated with the generation

of welding fumes.

Accordingly, OSHA is proposing an 8hour TWA limit of 5 mg/m3 for these particular types of welding fumes, measured as total particulate inside the welder's breathing zone. The Agency believes that this limit will substantially reduce the significant risk of material health impairment to which manual metal arc or oxy-acetylene welders of iron, mild steel, or aluminum are exposed in the absence of an OSHA limit in construction, maritime, and agriculture. In addition, promulgation of this limit will make OSHA's PEL for these fumes consistent across all regulated sectors.

ZINC OXIDE (FUME) CAS: 1314–13–2; Chemical Formula: ZnO H.S. No. 1437

In construction and maritime, OSHA's permissible exposure limit for zinc oxide fume is 5 mg/m³ as an 8-hour TWA. There is no limit in agriculture. The ACGIH recommends a 5 mg/m³ TLV*-TWA and also has a TLV*-STEL of 10 mg/m³. NIOSH recommends a 5-mg/m³ 10-hour TWA limit with a 15-minute ceiling of 15 mg/m³. In construction and maritime, OSHA is retaining the 5-mg/m³ 8-hour TWA limit and proposing to add a STEL of 10 mg/m³ for zinc oxide; the Agency is also proposing these limits

in agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limits being proposed, which are the limits recently established for this substance in general industry.

Zinc oxide exposures of guinea pigs that lasted only an hour caused a drop in body temperature, followed 6 to 18 hours later by an increase above normal levels (Turner and Thompson 1926/Ex. 1–1124). The animals in the high-exposure group (2500 mg/m³ for 3 to 4

hours) died after exposure.

When heated, zinc oxide produces a white fume. The most prevalent toxic effect of zinc oxide fume is a condition known as "metal fume fever," whose symptoms include chills, fever, muscular pain, nausea, and vomiting (Turner and Thompson 1926/Ex. 1-1124). Studies in the workplace have shown that welders exposed to zinc oxide fume at concentrations of 320 to 580 mg/m3 reported nausea, with the development of chills, shortness of breath, and severe chest pains 2 to 12 hours later. Most workers took approximately 4 days to recover, and some eventually developed pneumonia (Hammond 1944/Ex. 1-981). Other studies have reported the frequent occurrence of chills in workers exposed to zinc oxide at levels as low as 5 mg/ m3 (Hickish 1963 and Wall 1970, both as cited in ACGIH 1986/Ex. 1-3, p. 645). Hammond (1944/Ex. 1-981) reported that workers exposed to 8 to 12 mg/m3 of zinc oxide fume did not suffer from metal fume fever. However, subsequent experience has shown that exposures even to a concentration of 5 mg/m2 can cause this syndrome (Hickish 1963 and Wall 1970, both as cited in ACGIH 1986/ Ex. 1-3, p. 646). NIOSH's criteria document (1975d) reported that exposures to the fume at the 5 mg/m3 level could cause chronic respiratory effects.

Based on this evidence in humans and animals, OSHA is retaining its 5-mg/m3 8-hour TWA limit and proposing to add a STEL of 10 mg/m3 for zinc oxide in construction and maritime; the Agency is also proposing these limits in agriculture. OSHA preliminarily concludes that these limits will protect workers in these sectors from the significant risks of metal fume fever and chronic respiratory damage associated with exposure to zinc oxide fumes. These effects constitute material health impairments and are associated both with acute and chronic exposure to zinc oxide fumes. Promulgation of these limits will also make OSHA's PELs for this substance consistent across all regulated sectors.

add a STEL of 10 mg/m³ for zinc oxide; ZIRCONIUM COMPOUNDS (as Zr) the Agency is also proposing these limits CAS: 7440–67–7; Chemical Formula: Zr

H.S. No. 1439

The OSHA PEL for zirconium compounds in construction and maritime is an 8-hour TWA of 5 mg/m3, measured as zirconium. There is no limit in agriculture. The ACGIH has established a TLV*-TWA of 5 mg/m3. supplemented by a 10-mg/m3 STEL, for these substances. There is no NIOSH REL. OSHA is retaining the 8-hour TWA and proposing to add a STEL of 10 mg/ m³ for these substances in construction and maritime and is also proposing to extend these limits to agriculture. This action would make OSHA's PEL for the compounds of zirconium consistent across all sectors.

Zirconium compounds may be either bluish-black powders or grayish-white lustrous metals. Zirconium metal is used in nuclear technology, photo flash bulbs. vacuum tubes, and in steel manufacture. Compounds of zirconium are used in ceramics, enamels, porcelain, abrasives, and in making refractories. The compounds are also used in hightemperature batteries and as textile water-repellant and tanning agents (ACGIH 1986, p.647). Some of these substances also found use in pesticides. When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

The toxic effects of inhalation exposures to zirconium compounds include the formation of granulomas, both in the lungs and on the skin. Sax (1984) reports cases of pulmonary granulomas in workers exposed to zirconium aerosols. In laboratory animals, oral toxicity is low (NIOSH 1972b), and inhalation studies conducted in experimental animals for 1 year at levels of 3.5 mg zirconium/m³ dust and mist resulted in limited toxicity (Stokinger 1981c/Ex. 1–1134).

In the earlier rulemaking, NIOSH (Ex. 8-47) recommended that zirconium tetrachloride not be included in this group of zirconium compounds because an animal study by Spiegl et al. (1956, as cited in ACGIH 1986/Ex. 1-3, p. 647) showed effects in animals at 6 mg/m3. NIOSH (Ex. 8-47) recommended that OSHA establish a separate PEL for zirconium tetrachloride. However, because one of the program goals of this rulemaking is to make OSHA's limits consistent across all industry sectors, OSHA is proposing an 8-hour TWA PEL of 5 mg/m3 and a 15-minute STEL of 10 mg/m3 for all zirconium compounds, including zirconium tetrachloride. OSHA preliminarily concludes that the 5 mg/m3 TWA and 10 mg/m3 STEL limits for the zirconium compounds, measured

as zirconium, will protect workers in construction, maritime, and agriculture from the significant risk of pulmonary effects potentially associated with exposure to these substances. The Agency believes that these effects constitute material health impairments and that the proposed PELs are necessary to substantially reduce the risks of these health effects. Promulgation of these limits also will make OSHA's PELs for these compounds consistent across all regulated sectors.

Preliminary Conclusions for This Group of Systemic Toxicants

For the group of systemic toxicants shown in Table C8–1, OSHA preliminarily concludes that the risks associated with occupational exposures are significant. As Table C8–2 shows, the systemic effects caused by such

exposures include cancer, liver and kidney damage, testicular damage, fetal poisoning, central nervous system depression, and asthma, each of which constitutes material impairment of health within the meaning of the Act. Affected employees in construction, maritime, and agriculture may experience dizziness, nausea, generalized weakness, respiratory irritation, blood in the urine, chest tightness, hives, and necrosis of the cornea. These effects represent significant impairments of health and functional capacity, and reducing the limits for these systemic toxins will substantially reduce these significant risks. In addition, promulgation of the proposed limits will make OSHA's PELs for these systemic toxins consistent across all regulated sectors.

9. Substances for Which Proposed Limits Are Based on No-Observed-Adverse-Effect Levels Introduction

For a group of 35 toxic substances, OSHA is proposing limits for the construction, maritime, and agriculture industries based on evidence that these substances cause toxic responses at higher levels but have been shown not to produce adverse effects in animals or exposed populations at the limits being proposed. The proposed PELs for this group of substances have thus been set in reference to no-observed-adverseeffect levels, or NOAELS. These substances are shown in Table C9-1. along with their CAS numbers and H.S. numbers. The 1987-88 ACGIH TLV®, the NIOSH REL (if any), the current OSHA PEL in construction and maritime, and the proposed OSHA PEL in construction, maritime, and agriculture are also shown in Table C9-1. Promulgation of the limits being proposed will make OSHA's PELs for these substances consistent across all regulated sectors.

¹ OSHA's TWA limits are for 8-hour exposures; its STELs are for 15 minutes unless otherwise specified; and its ceilings are peaks not to be exceeded for any period of time; OSHA's PELs do not currently apply in Agriculture.

² The ACGIH TLV®-TWA is for an 8-hour exposure; its STELs are 15-minutes limits not to be exceeded more than 4 times per day with a minimum of 60 minutes between successive STEL exposures; and its ceilings are peaks not to be exceeded for any period of time.

³ NIOSH TWA limits are for 10 hour/day, 40 hour/week exposures unless otherwise specified, and its ceilings are peaks not to be exceeded for any period of time unless a duration is specified in parentheses.

⁴ Because the composition of this material varies greatly, the ACGIH recommends that the content of benzene, other aromatics, and additives should be determined to arrive at the appropriate TLV®.

Description of the Health Effects

The substances included in this group cause a wide range of adverse health effects in both animals and humans. Unlike most of the other groupings described in this preamble, these toxicants do not affect the same target organ or system: Some are central nervous system depressants, several are upper respiratory tract irritants, and still others have their primary effect on the heart, liver, or kidney. The commonality among these otherwise diverse substances is that apparent noobserved-adverse-effect levels (NOAELs) have been defined for all of them; that is, there are data demonstrating that overt toxic effects caused by exposure to these substances

at higher levels do not occur below a certain "no-observed-adverse-effect" level. Permissible exposure limits have been developed for these chemicals on the basis of these no-observed-adverseeffect levels. Table C9-2 shows the health effects that have been observed in humans or animals that are believed likely to occur in humans who are exposed to these substances.

TABLE C9-2.—HEALTH EFFECTS ASSOCIATED WITH SUBSTANCES FOR WHICH PROPOSED LIMITS ARE BASED ON NO-OBSERVED-ADVERSE-EFFECT LEVELS

H.S. number/chemical name		CAS No.	Health effects observed in animals	Health effects observed/projected in humans	
1029	Atrazine	1912-24-9	Irritation, ataxia, dyspnea, convulsions, liver	Irritation, systemic effects, contact dermatitis

TABLE C9-2.—HEALTH EFFECTS ASSOCIATED WITH SUBSTANCES FOR WHICH PROPOSED LIMITS ARE BASED ON NO-OBSERVED-ADVERSE-EFFECT LEVELS—Continued

	H.S. number/chemical name	CAS No.	Health effects observed in animals	Health effects observed/projected in humans
1056	p-tert-Butyl-toluene	98-51-1	Central nervous system depression, irritation,	Nasal irritation, nausea, headache, weakness
1085	Chlorodifluoromethane	75-45-6	tiver and kidney changes. Central nervous system effects, cardiac sensi-	Central nervous system effects, cardiac sens
1090	o-Chlorotoluene	95-49-8	tization, possible carcinogenicity. Weakness, vasodilation, incoordination, convul-	tization. Neuropathic effects, irritation.
			sions, irritation.	The state of the s
1110	Cyclonite	121-82-4	Convulsions, death	Central nervous system effects, convulsions unconsciousness, death.
2056	Dibutylphthalate	84-74-2	Irritation, central nervous system effects, repro- ductive effects	Irritation, central nervous system effects, reproductive effects.
1117	2,6-Di-tert-butyl-p-cresol	128-37-0	Irritation, lung and liver damage, cancer promo-	Irritation, skin sensitization.
2059	1,2-Dichloroethylene	540-59-0	Lung, liver, blood effects	Narcosis, Irritation.
1134			Irritation, liver and kidney damage	Irritation.
1136		84-66-2	Irritation, central nervous system effects, liver	
			damage.	Central nervous system effects, polyneuritis, vestibular dysfunction.
1144	Dinitolmide	148-01-6	Liver changes	Hepatic effects.
1147		122-39-4	Liver, kidney, spleen changes, developmental effects.	Tachycardia, bladder symptoms, hypertension eczema, eye and mucous -membrane imitation.
1153	Diuron	330-54-1	Anemia, methemoglobinemia, spleen and liver effects, teratogenic effects.	Anemia, methemoglobinemia, eye, skin, and
2073	Endrin	72-20-8	Reproductive, developmental effects	respiratory irritation.
2099	LPG	68476-85-7	Central nervous system depression	Convulsions, brain damage. Drowsiness, headache,-vomiting.
1249	Methyl acetate	79-20-9	Eye and skin irritation, CNS depression	Eye, mucous membrane irritation, chest tight ness, narcosis, destruction of optic nerve
1275	Metribuzin	21087-64-9	CNS depression, thyroid and liver changes	Narcosis, thyroid and liver damage.
2121	1-Nitropropane	108-03-2	Reproductive, developmental effects	Convulsions.
1297	Oil mist (mineral)	8012-95-1	Eye, skin, and respiratory irritation	Lung irritation, pneumonitis, photosensitization dermatitis.
1312	Petroleum distillates (naphtha)		Motor incoordination, convulsions	Eye and throat irritation, CNS depression,
1327	m-Phthalodinitrile	626-17-5	Skin irritation	Skin irritation.
1332	Platinum, metal	7440-06-4	Tumorigen by implantation	
1346	Resorcinol	108-46-3	Eye, skin irritation	Irritation, systemic effects (methemoglobinemia, cyanosis) pigmentary dermatosis.
2139	Rotenone (commercial)	83-79-4	Irritation, central nervous system effects, liver and kidney damage, cancer.	Irritation, nausea, vomiting, gastro-intestinal effects
2146	Sulphur hexafluoride	2551-64-4	Central nervous system effects, asphyxiation	Central nervous system effects, asphyziation.
1382	Tantalum, metal dust and oxide	7440-25-7	Bronchitis, pneumonitis, hyperemia, tumorigen by implantation	Pulmonary effects.
2153	1,1,2,2-Tetrachloro-2,2-diffuoroethane	76-12-0	Central nervous system depression; blood and liver changes.	Dermatitis.
2154	1,1,1,2-Tetrachloro-2,2-difluoroethane	76-11-9	Irritation, narcosis	
2164	Trifluoromonobromomethane	75-63-8	Cardiac irregularities, seizures	Cardiac irregularities.
1410	Trimethyl phosphite	121-45-9	Teratogenicity, eye and skin irritation, lung damage.	Lung, skin, eye irritation.
1415	Triphenyl amine	603-34-9	Skin irritation	Skin irritation.
2165	Triphenyl phosphate		Cholinesterase inhibition.	Cholinesterase inhibition.
1418	Uranium (insoluble compounds)	7440-61-1	Kidney damage, blood disorders	Kidney damage, blood effects.

Dose-Response Relationships and No-Observed-Adverse-Effect Levels

The concept of setting limits based on a NOAE level assumes that there is a concentration at which repeated and prolonged exposure to a toxic substance causes no observable adverse effect in the majority of workers. A similar concept is widely used by Federal agencies, such as the Food and Drug Administration and the Environmental Protection Agency, to set contaminant tolerances, acceptable daily intake values, and other limits.

All of the proposed limits for this group of substances have been set at or below a no-observed-adverse-effect or minimal effect level, regardless of the specific health endpoint against which protection is sought. At least in part, the exposure limits for the 35 substances

listed in Table C9–1 are based on data indicating that these limits are already being maintained in work environments and that these levels are both feasible and unlikely to be associated with adverse health effects or signs and symptoms in exposed employees. The proposed limits will also protect against any effects these substances would cause through exposure to higher concentrations. Even at relatively low exposure concentrations, many of the substances in this group cause effects that can be severe and irreversible.

The following discussions describe OSHA's preliminary findings for the substances in this group and illustrate the material impairments of health potentially faced by workers exposed to these toxicants in the construction, maritime, and agriculture industries.

ATRAZINE CAS: 1912–24–9; Chemical Formula: $C_8H_{14}ClN_{\delta}$ H.S. No. 1029

In construction, maritime, and agriculture, OSHA has no limit for atrazine. The ACGIH has a TLV®-TWA of 5 mg/m³: NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed for atrazine in these sectors. OSHA is proposing an 8-hour TWA PEL of 5 mg/m³ for atrazine in the construction, maritime, and agriculture industries. This is the limit recently established for atrazine in general industry.

Atrazine is a white, crystalline compound. This substance is a herbicide for grasses, broadleaf weeds, corn, sorghum, and sugarcane and is also used in industrial and commercial

herbicidal applications (HSDB 1990). Atrazine is the best known of the striazine herbicides. When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Atrazine is a mild irritant of the eyes and skin in humans and animals; at acutely toxic doses, this substance causes ataxia, dyspnea, and convulsions in animals (Hayes 1982, p. 562). The LCso in rats is 5200 mg/m3 for 4 hours, the oral LDso in the same species is 672 mg/ kg, and the dermal LD50 in rabbits is 7500 mg/kg (RTECS 1990). Applied to the skin of rats, atrazine caused marked erythema but no systemic toxicity (Hayes 1982, p. 562). Instilled into the eyes of rabbits, this substance caused severe irritation (RTECS 1990). In a subacute experiment in rats given atrazine by gavage at doses of 100, 200, or 400 mg/kg/day for 14 days or at 600 mg/kg/day for 7 days, a significant and dose-dependent increase in liver weight was seen in all groups; at autopsy, histopathological changes were seen in the livers of all but the 100-mg/kg group (Santa Maria, Moreno, and Lopez-Campos 1987, in J. Appl. Toxicol. 7(6):373-378). Atrazine was embryotoxic when administered to rats in high doses (800-2000 mg/kg) on days 3, 6, and 9 of gestation; no effects were seen at lower concentrations (Clayton and Clayton 1981, p. 2775). A recent study in rats and rabbits (Infurna, Levy, Meng et al. 1988, in J. Toxicol. Environ. Hlth. 24(3):307-320) indicates that atrazine is not teratogenic in these species at doses below those causing maternal toxicity. Atrazine has been tested for carcinogenicity in mice and rats. In mice, 21.5 mg/kg/day was administered by gavage from days 7 to 28 of life, and no increase in the incidence of tumors was seen (Innes et al. 1969, in EPA Health Advisory 1987). A recent study (Pinter, Torok, Surjan et al. 1989, in Magy. Onkol. [Hungarian Oncology] 33(4):211-221), however, found dosedependent increases in all malignancies in rats of both sexes, benign breast tumors in males, and uterine carcinomas in females, confirming atrazine's carcinogenicity in animals.

In humans, there is one report of severe contact dermatitis in a farmer who sprayed atrazine; patch testing confirmed atrazine's involvement in this episode (Schlichter and Bent 1972, in J. Iowa Med. Soc. 62:419–420). Atrazine has also been found to induce unscheduled DNA synthesis in human cells, which suggests a potential genetic hazard in humans (Loprieno et al. 1980,

Mutat. Res. 74(3):2500). The possible role of triazine herbicides in the etiology of ovarian cancer in women was evaluated in a recent case-referent study (Donna, Crosignani, Robutti et al. 1989, Scand. J. Work Environ. Hlth. 15(1):47–53). These authors concluded that previous exposure to triazines was associated with a significant relative risk of 2.7 for ovarian neoplasms.

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 5 mg/ m3 for atrazine in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that this limit will protect employees in these sectors from the significant risk of neuropathic and metabolic effects associated with exposure to atrazine. OSHA considers these effects material health impairments and believes that the proposed PEL is necessary to substantially reduce these significant risks. In addition, promulgation of this PEL will make OSHA's limit for atrazine consistent across all regulated sectors. AZINPHOS-METHYL

CAS: 86–50–0; Chemical Formula: C₁₀H₁₂N₃O₃PS₂ H.S. No. 2014

OSHA's PEL for azinphos methyl in general industry, construction, and maritime workplaces is 0.2 mg/m³ as an 8-hour TWA. OSHA also has a skin notation for this substance. There is no REL in agriculture. The ACGIH TLV²-TWA is 0.2 mg/m³, with a skin notation; NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed for azinphos methyl. OSHA is proposing an 8-hour TWA PEL of 0.2 mg/m³, and a skin notation, for this substance in agriculture. Promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

In pure form, azinphos methyl is a colorless or white crystalline substance, although the technical grade is a brown, waxy solid (Hayes 1982, p. 358). This substance is a widely used nonsystemic insecticide and acaricide (Hayes 1982, p. 358). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Azinphos methyl belongs to the organophosphate class of pesticides. It is an anticholinesterase agent which inhibits cholinesterase, causing acetylcholine to accumulate at synapses in the nervous system, skeletal muscle, and secretory glands. Azinphos methyl exerts this effect by inhalation, percutaneous absorption, or ingestion. The oral LD₅₀ in rats is 7 mg/kg, and the LC₅₀ in the same species is 69 mg/m³ for

1 hour (RTECS 1990). The dermal LDso in rats is 220 mg/kg (RTECS 1990). Rats fed 20 ppm azinphos methyl in their diets for 60 days showed inhibition of brain and red blood cell cholinesterase (ACGIH 1986, p. 46). Rats inhaling this substance at a concentration of 4.7 mg/m3 for 6 hours/day, 5 days/week for 12 weeks showed both red blood cell and plasma cholinesterase inhibition; inhalation of a 1.24-mg/m3 concentration on the same regimen was without effect (Haves 1982, pp. 358-359). Azinphos methyl has caused developmental and reproductive effects when administered orally to pregnant rats and mice (RTECS 1990). This substance also is mutagenic in mammalian test systems (RTECS 1990).

Overexposure to azinphos-methyl causes respiratory and ocular effects (including wheezing, a feeling of tightness in the chest, laryngeal spasms, excessive salivation, cyanosis, blurring of vision, lacrimation, runny nose, and frontal headache) (Proctor, Hughes, and Fischman 1988, p. 86). If this substance is accidentally ingested, gastrointestinal symptoms, including nausea, vomiting, cramps, and diarrhea occur within 2 hours of ingestion. Absorption of azinphos methyl through the skin causes localized sweating and muscular fasciculation, indicating localized poisoning (Proctor, Hughes, and Fischman 1988, p. 86).

Regardless of the route of exposure, azinphos methyl produces muscular weakness, twitching, convulsions, coma. loss of reflexes, and paralysis of the respiratory muscles. If the victim does not die during the acute episode, complete recovery may occur within a week, although the individual is likely to remain hypersensitive to anticholinesterase agents for some period of time thereafter (Proctor and Hughes 1978, p. 114). Long-term exposure to concentrations of azinphos methyl that are too small to cause acute symptoms may eventually lead to systemic poisoning (Proctor and Hughes 1978, p. 114).

Based on this evidence, OSHA is proposing an 8-hour TWA PEL for azinphos methyl of 0.2 mg/m³, with a skin notation for those agricultural uses of this substance that are not covered by FIFRA. The Agency believes that, in the absence of a PEL, workers in agricultural establishments may be subject to the significant risk of cholinesterase inhibition posed by exposure to this substance. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

BROMACIL CAS: 314-40-9; Chemical Formula: C₀H₁₂BrN₂O₂ H.S. No. 1041

In construction, maritime, and agriculture, OSHA has no permissible exposure limit for bromacil. The ACGIH's TLV*-TWA for bromacil is 1 ppm. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. The Agency is proposing an 8-hour TWA PEL of 1 ppm for this substance, which is consistent with the PEL recently established for bromacil in general industry.

Bromacil is a white crystalline solid that is used as a herbicide in commercial, industrial, and agricultural applications (HSDB 1989). This substance is odorless (HSDB 1989). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and

Rodenticide Act (FIFRA).

Bromacil is an irritant of the eyes, mucous membranes, and upper respiratory tract. The oral LD50 in rats is 641 mg/kg (RTECS 1990). All rats survived inhalation of a bromacil concentration of 4800 mg/m3 for 4 hours (ACGIH 1986, p. 64). The dermal LD50 in rabbits is reported to be greater than 5000 mg/kg (Clayton and Clayton 1981, p. 2749). Applied to the skin of guinea pigs, bromacil caused mild to moderate skin irritation (Clayton and Clayton 1981, p. 2749). Instilled into rabbit eyes. this substance caused reversible conjunctival irritation but no corneal damage (Grant 1986, p. 536). Male rats were given bromacil 5 days/week for 2 weeks at oral doses of 650, 1035, or 1500 mg/kg; five of six rats died after five doses at the highest level, one died after 10 doses at 1035 mg/kg, and none died at the lowest dose. At autopsy, focal cell hypertrophy and hyperplasia of the liver were seen (NRC 1977, Drinking Water and Health, p. 540). Rats were fed bromacil at 50, 500, 2500, 5000, 6000, or 7000 ppm for 90 days. Rats in the 5000 ppm or higher groups developed hyperthyroidism (NRC 1977, p. 540). In another study in rats fed bromacil at 50, 250, or 1250 ppm for 2 years, rats in the 1250-ppm group developed hyperplasia of the thyroid; one female rat in the 1250-ppm group developed a follicular adenoma (NRC 1977, p. 541).

In 2-year feeding studies in rats and dogs, no-observed-adverse-effect dietary concentrations were determined to be 12.55 mg/kg/day (1.25 ppm) for rats and 1250 for dogs (Sherman and Kaplan 1975/Ex. 1–572).

Bromacil is known to cause eye, nose, and throat irritation in workers handling formulations containing this substance. Skin irritation has also been reported (HSDB 1990; Hazardous Substance Fact Sheet 1985). No reports of systemic toxicity caused by exposure to bromacil appear in the literature.

Based on this evidence, OSHA is proposing an 8-hour TWA permissible exposure limit of 1 ppm for bromacil in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that this limit will protect employees against the significant risk of thyroid damage and irritation, both material health impairments that occur with exposure to this substance. OSHA believes that the proposed limit is necessary to substantially reduce this risk among workers in these sectors. In addition, promulgation of this PEL will make OSHA's limit for bromacil consistent across all regulated sectors.

p-tert-BUTYLTOLUENE CAS: 98-51-1; Chemical Formula: (CH_s)₃C-C_sH₄CH₅ H.S. No. 1058

OSHA's PEL for p-tert-butyltoluene in construction and maritime is an 8-hour TWA PEL of 10 ppm; the Agency is proposing to retain this limit in these industries, to supplement it with a 20-ppm STEL, and to extend both the 8-hour TWA and the STEL to workplaces in agriculture. The ACGIH has a TLV*-TWA of 10 ppm and a TLV*-STEL of 20 ppm for p-tert-butyltoluene. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. These are the limits recently established for p-tert-butyltoluene in general industry.

p-tert-Butyltoluene is a colorless liquid with an aromatic, gasoline-like odor. This substance is used as a solvent for resins, in the manufacture of pharmaceuticals, and as a chemical intermediate (HSDB 1989).

p-tert-Butyltoluene is an irritant of the eyes, mucous membranes, and upper respiratory tract with acute exposure and a liver and kidney toxin with chronic exposure. The oral LDso in rats is 1800 mg/kg, the LCoo in the same species is 165 ppm for 8 hours, and the dermal LD50 in rabbits is 19,600 mg/kg (RTECS 1990). In contact with the eyes or skin of rabbits, p-tert-butyltoluene caused mild irritation (RTECS 1990; Grant 1974, p. 212). Acutely poisoned animals showed staggering, difficult breathing, and paralysis before death; some animals showed signs of eye and upper respiratory tract irritation and others convulsed (Proctor, Hughes, and Fischman 1988, p. 110; RTECS 1990). Rats repeatedly exposed to a 50-ppm concentration of p-tert-butyltoluene showed liver and kidney changes and damage to the spinal cord at autopsy

(Hine, Ungar, Anderson, et al. 1954/Ex. 1–983). The no-effect level in rats exposed daily for 28 weeks was 25 ppm (Gerarde 1960a, in ACGIH 1986, p. 85/ Ex. 1–3).

In humans, nasal irritation, nausea, malaise, headache, and weakness have been seen with exposure to p-tertbutyltoluene at concentrations between 5 and 160 ppm (Hine, Ungar, Anderson et al. 1954/Ex. 1-983). At a concentration of 80 ppm, a moderate degree of eye irritation was reported by these volunteers. These authors also noted cardiovascular effects, as well as effects on the central nervous system, the skin, and the respiratory tract. Half of the subjects exposed to p-tert-butyltoluene developed tremor and anxiety, and 25 percent of exposed individuals showed evidence of chemical contact irritation of the respiratory tract (Hine, Ungar, Anderson et al. 1954/Ex. 1-983].

Based on this evidence, OSHA is proposing to retain its 8-hour TWA of 10 ppm for p-tert-butyltoluene in the construction and maritime industries, to add a STEL of 20 ppm, and to extend both the TWA and STEL to agricultural workplaces. The Agency preliminarily concludes that the STEL and TWA will protect workers in these sectors against the significant risks of irritation and central nervous system effects associated with exposure to this substance. The Agency believes that these adverse health effects constitute material impairments of health and that the proposed limits are necessary to reduce these significant occupational risks substantially. In addition, promulgation of the proposed limits will make OSHA's PELs for p-tertbutyltoluene consistent across all regulated sectors.

CHLORODIFLUOROMETHANE CAS: 75-45-6; Chemical Formula: CHClF₂ H.S. No. 1085

OSHA currently has no limit for chlorodifluoromethane (Freon 22) in the construction, maritime, or agriculture industries. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed by OSHA. The ACGIH has a TLV® of 1000 ppm as a TWA and 1250 ppm as a STEL. The Agency is proposing an 8-hour TWA PEL of 1000 ppm for this substance; this is the limit recently established for chlorodifluoromethane in general industry.

Chlorodifluoromethane is a colorless, nearly odorless, nonflammable gas. This substance is used as an aerosol propellant, a refrigerant, a foam-blowing agent, and a solvent (HSDB 1990).

Exposure to very high atmospheric levels of Freon 22 causes stimulation and then depression of the central nervous system, followed by asphyxiation. The LCoo in rats is 350,000 ppm for 15 minutes (RTECS 1990). Rats and guinea pigs exposed to concentrations of 75,000 to 100,000 ppm over a 2-hour period exhibited excitation and disequilibrium; narcosis was observed at 200,000 ppm and mortality at 300,000 and 400,000 ppm (Weigand 1971/Ex. 1-1102). In rabbits, the minimum concentration altering reflex responses was 11,000 to 20,000 ppm (Karpov 1963, as cited in ACGIH 1986/Ex. 1-3, p. 127). Studies in guinea pigs reported that no animals died as a result of exposure for 2 hours to a concentration of 200,000 ppm, but mild clinical changes were observed at 50,000 ppm and minimal effects were seen at 25,000 ppm (Underwriters' Laboratories, Inc. 1940, as cited in ACGIH 1986/Ex. 1-3, p. 127). Karpov (1963, as cited in ACCIH 1986/Ex. 1-3, p. 127) reported the results of a 10-month study on the effects of exposure by inhalation of chlorodifluoromethane in rats, guinea pigs, dogs, and cats who were exposed 6 hours/day, 5 days/week to 2,000 or 14,000 ppm; alterations in weight, endurance, and blood chemistry, and pathology of the lungs, central nervous system, heart, liver, kidney, and spleen were seen in rats, mice, and rabbits exposed to 14,000 ppm. At a concentration of 2000 ppm, rats and mice showed no effects (Karpov 1963, as cited in ACGIH 1986/Ex. 1-3, p. 127). In dogs, cardiac sensitization was not observed at the 25,000-ppm level but did occur at the 50,000-ppm level (Reinhardt, et al. 1971/ Ex. 1-78). Rats and mice were exposed to chlorodifluoromethane at concentrations of 1000 or 5000 ppm for 4 hours/day, 5 days/ week for 104 weeks (rats) or 78 weeks (mice). No carcinogenic responses were seen in animals of either sex or species (Maltoni, Lefemine, Tovoli, et al. 1988, in Annals NY Acad. Sci. 534:261-282). In a study in rats given chlorodifluoromethane orally, however, an increase in tumor incidence was seen, and a marginal increase in the incidence of subcutaneous fibrosarcomas and Zymbal-gland tumors occurred in male rats exposed to a high concentration of chlorodifluoromethane. The International Agency for Research on Cancer concluded in 1987 that the evidence for the carcinogenicity of chlorodifluro-methane in animals was limited (IARC 1987, Suppl. 7, p. 149).

In humans, exposure to chlorodifluoromethane causes central nervous system effects, including

nausea, vomiting, and narcosis (Braker and Mossman 1980, p. 170). In contact with the skin, liquid chlorodifluoromethane causes skin irritation and frostbite (Braker and Mossman 1980, p. 170). A study of pathology laboratory workers exposed to high short-term concentrations (300 ppm) of this substance while preparing frozen sections showed an association between episodes of heart palpitations and exposure and also noted that several of these young male workers had chronic arrhythmias (Rom 1983, p. 361). A study of 539 refrigeration workers occupationally exposed to a number of chlorofluorocarbons, including chlorodifluoromethane, for periods ranging from 6 months to 20 years was inconclusive (IARC 1987.

Suppl. 7, p. 149). Based on this evidence, the Agency is proposing an 8-hour TWA limit of 1000 ppm for chlorodifluoromethane in the construction, maritime, and agriculture industries. OSHA preliminarily concludes that this limit will provide protection for workers in these sectors against the central nervous system effects asphyxiant effects, and cardiac sensitization effects, that are associated with exposure to this substance. The Agency believes that this limit is necessary to reduce substantially these significant risks of material health impairment. In addition, promulgation of this PEL will make OSHA's limit for chlorodifluoromethane consistent across all regulated sectors.

O-CHLOROTOLUENE CAS: 95-49-8; Chemical Formula:

C,H,Cl H.S. No. 1090

OSHA has no limit for o-chlorotoluene in the construction, maritime, and agriculture industries. The ACGIH has a TLV*-TWA of 50-ppm and a 75-ppm TLV®-STEL for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing a 50-ppm 8-hour TWA for o-chlorotoluene. This is the limit recently established for this substance in general industry.

O-Chlorotoluene is a colorless liquid. It is used as a solvent and an ingredient in pharmaceuticals, dyes, and rubber formulations (Hazardous Substance Fact Sheet 1985).

O-Chlorotoluene is an irritant of the eyes, mucous membranes, and upper respiratory tract. The oral LD50 in rats is greater than 1600 mg/kg (Ely 1971, in EPA 1989). The oral LD50 in mice and rats are 4400 and 5700 mg/kg, respectively; acutely poisoned animals showed incoordination, convulsions,

dizziness, disorientation, incoordination, and rapid breathing before death (Pis'ko et al. 1981, in EPA 1989). When the undiluted material was administered orally in doses ranging from 50 to 100 mg/kg, rats experienced weakness and vasodilation at the higher dose levels, but all survived and were gaining weight 2 weeks later (ACGIH 1986/Ex. 1-3, p. 137). When the undiluted liquid was applied to the skin of guinea pigs in doses of 1 ml/kg or 10 ml/kg for 24 hours, moderately severe skin irritation occurred at both dose levels. The guinea pigs lost weight over the 2-week period following application, indicating percutaneous absorption of this substance; however, no dermal LD50 has been established for o-chlorotoluene. One drop of undiluted material in the eyes of rabbits produced a delayed erythema of the conjunctiva, although this effect cleared after 14 days (Ely 1971, as cited in ACGIH 1986/Ex. 1-3, p. 137). Rats exposed to an atmosphere of 21 mg/L (or about 4000 ppm) for 6 hours exhibited loss of coordination within 1.5 hours, prostration at 1.75 hours, and tremors at 2 hours. At 14,000 ppm, rats showed loss of coordination, vasodilation, labored respiration, narcosis, and eye tearing; however, rats exposed to 4000 or 14,000 ppm survived. At 175,000 ppm, one of three rats died (Ely 1971, as cited in ACGIH 1986/Ex. 1-3, p. 137). Rats given 114 or 570 mg/kg/ day o-chlorotoluene by gavage for 2 months showed dose-dependent effects on hemopoiesis, liver, kidneys, and the central nervous system (Pis'ko 1981, in EPA 1989). Sub-chronic studies in animals given oral doses (5, 20, or 80 mg/kg/day in dogs; 20, 80, or 320 mg/kg in rats) of o-chlorotoluene for 97 days (dogs) or 104 days (rats) reported no treatment-related changes in dogs; rats showed decreases in body weight and increases in adrenal weight (two highdose groups) and in heart and testes weight (in the highest dose group only) (Gibson et al. 1974a and b, in EPA 1989).

Although no poisonings caused by ochlorotoluene have been reported in humans, this substance is expected to cause irritation and central nervous system effects in exposed individuals on the basis of effects seen in animals.

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 50 ppm for o-chlorotoluene in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that this limit will protect workers in these sectors from the significant risks of eye and skin irritation and systemic poisoning associated with exposure to ochlorotoluene. OSHA considers these adverse effects material impairments of health and believes that the proposed

PEL is necessary to reduce substantially these risks. In addition, promulgation of the proposed PEL will make OSHA's limit for o-chlorotoluene consistent across all regulated sectors.

CYCLONITE (RDX)

CAS: 121-82-4; Chemical Formula:

C₃H₆N₆O₆

H.S. No. 1110

OSHA's permissible exposure limit for cyclonite (RDX) in the construction and maritime industries is 10 mg/m³ as an 8-hour TWA and 20 mg/m³ as a STEL. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the proposed limit. The 1987-1988 ACGIH assigned an 8-hour TLV®-TWA limit of 1.5 mg/m³ and a TLV®-STEL of 3 mg/m³, with a skin notation, to this substance. OSHA is proposing a 1.5-mg/m³ 8-hour TWA PEL for cyclonite, and a skin notation; this is the limit recently established for cyclonite in general industry.

Cyclonite is a white, crystalline powder. This substance is used as an explosive and a rat poison. When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide

Act (FIFRA).

Cyclonite is toxic to the central nervous system in humans and animals. The oral LD50 in rats is 100 mg/kg (RTECS 1990). Acutely poisoned animals showed labored breathing and convulsions before death (Cholakis, Wong, Van Goethen et al. 1980, in Midwest Research Institute report; Burdette, Cook, and Dyer 1988, Toxicol. Appl. Pharmacol. 92(3):436-444). Rats given oral doses of cyclonite ranging from 0 to 60 mg/kg were monitored for 8 hours after dosing. An increase in the incidence of spontaneous and audiogenic seizures was observed at doses as low as 10 to 12.5 mg/kg, and significant seizure activity was induced by doses of 25 mg/kg and above. The authors of this study concluded that cyclonite is a potent convulsant. Rats fed 40 mg/kg/day for 90 days showed decreased weight gain but no other signs of toxicity, while 17 of 35 rats fed 50 mg/ kg/day died (Cholakis et al. 1980; Clayton and Clayton 1981, p. 4197).

In industry, reports of poisonings as a result of occupational exposures to cyclonite were widespread as late as 1962 (Kaplan, Berghout, and Peczenik 1965/Ex. 1-338). Occupational overexposure causes central nervous system effects, including nausea, vomiting, convulsions, and unconsciousness. These clinical signs result from oral and inhalation exposures, and from skin absorption (Kaplan, Berghout, and Peczenik 1965;

Sunderman et al. 1944, as cited in ACGIH 1986/Ex. 1-3, p. 162; von Oettingen, Donahue, Yagoda et al. 1949/ Ex. 1-398). Convulsions have occurred in cyclonite workers without warning or, in some cases, after 1 or 2 days of insomnia and restlessness. Seizures were followed by amnesia, fatigue, weakness, and malaise, but complete recovery followed (Clayton and Clayton 1981, p. 4197). In an epidemiological study, Hathaway and Buck (1977/Ex. 1-418) reported that 8-hour TWA exposures to cyclonite at concentrations ranging up to 1.57 mg/m3 and averaging 0.28 mg/m³ caused no identifiable exposure-related abnormalities.

Based on this evidence, OSHA is proposing an 8-hour TWA limit of 1.5 mg/m3 TWA and a skin notation for cyclonite in the construction, maritime. and agriculture industries. The Agency preliminarily concludes that these limits are necessary to protect workers in these sectors from the significant risk of these exposure-related central nervous system effects, which constitute material health impairments. In addition, promulgation of the limit will make OSHA's PEL for cyclonite consistent across all regulated sectors. DIBUTYL PHTHALATE CAS: 84-74-2; Chemical Formula:

C₆H₄(CO₂C₄H₉)₂ H.S. No. 2056

In general industry, construction, and maritime, OSHA's permissible exposure limit for dibutyl phthalate is 5 mg/m³ as an 8-hour TWA. There is no limit in agriculture. The ACGIH has an 8-hour TLV³-TWA of 5 mg/m³ for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA limit of 5 mg/m³ for dibutyl phthalate in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Dibutyl phthalate is a colorless, oily liquid with a weak aromatic odor. It is used as an insect repellant in clothing and as a plasticizer, elastomer, solvent, textile lubricating agent, and perfume fixative and in paper coatings and explosives (NIOSH/OSHA Occupational Health Guideline 1981, p. 1; Hawley's 1987, p. 372). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Dibutyl phthalate causes primary irritation and central nervous system effects in humans and animals; it also causes reproductive effects in animals. The oral LD₅₀ in various species are 8000

mg/kg in rats, 5289 mg/kg in mice, and 10,000 mg/kg in guinea pigs (RTECS 1990). The LC₅₀ in mice is 25,000 mg/m³ for 2 hours (RTECS 1990). Mice exposed to a concentration of 250 mg/m3 dibutyl phthalate for 2 hours showed signs of eye and upper respiratory tract irritation; exposure to higher (not further specified) concentrations caused difficult breathing, ataxia, paresis, convulsions, and death due to respiratory paralysis (Varonin 1973, in ACGIH 1986, p. 176). Rats exposed to 0.5 mg/m3 concentrations of dibutyl phthalate mist 6 hours/day for 6 months gained weight more slowly and had greater lung and brain weights at autopsy than controls (Kawano 1980, in Proctor, Hughes, and Fischman 1988, p. 183). Rats given biweekly doses of dibutyl phthalate in oil at 1ml/kg of body weight for 6 weeks showed no adverse effects at autopsy, and a second group of rats maintained on this regimen for 1.5 years also displayed no adverse effects (Bornmann et al. 1956, in ACGIH 1986, p. 176). In female rats given 2520 mg/kg or 12,600 mg/kg dibutyl phthalate on days 1 through 21 of pregnancy, reproductive and embryotoxic effects were seen (RTECS 1990). Several species of animals were fed 2 g/kg of dibutyl phthalate for 10 days; there was evidence of testicular injury in mice and guinea pigs but not in hamsters (Gangolli 1982, in Proctor, Hughes, and Fischman 1988, p. 184). Oral or intraperitoneal administration of dibutyl phthalate to pregnant rats caused increased resorptions, fetal deaths, neural tube defects, and skeletal abnormalities (Peters and Cook 1973; Singh et al. 1972; and Shista and Nishimura 1982, in Proctor, Hughes and Fischman 1988, p. 183).

The lowest oral dose of dibutyl phthalate reported to be toxic in humans is 140 mg/kg (RTECS 1990). Contact of this substance with the eyes causes severe stinging and pain but no permanent injury (Grant 1986, p. 317). A chemical operator who accidentally swallowed 10 grams of dibutyl phthalate experienced nausea, dizziness, photophobia, lacrimation, and conjunctivitis, but promptly recovered (Cagianot 1954, in ACGIH 1986, p. 176). Women working with phthalates in the synthetic leather industry had a higher than normal incidence of miscarriages and menstrual disorders (Aldyreva et al. 1974, in HSDB 1985). Soviet investigators, who studied 147 workers employed in the artificial leather industry (where several phthalates are used) for 0.5 to 19 years reported that these workers complained of pain. numbness, and spasms in the

extremities; these effects were reported by workers employed for more than 6 years. Forty-seven of these workers had developed polyneuritis (Milkov et al.

Based on this evidence in humans and animals, OSHA preliminarily concludes that dibutyl phthalate causes primary irritation, central nervous system effects, and possible reproductive effects. OSHA believes that, in the absence of a limit for dibutyl phthalate, workers in agriculture are at significant risk of experiencing these exposurerelated adverse health effects. The Agency believes that establishing an 8hour TWA PEL of 5 mg/m3 for dibutyl phthalate is necessary to reduce significantly these risks of material health impairment. Promulgation of this limit for dibutyl phthalate in agriculture will make OSHA's PEL for this substance consistent across all OSHAregulated sectors.

1,2-DICHLOROETHYLENE CAS: 540-59-0; Chemical Formula: C2H2Cl2

H.S. No. 2059

In general industry, construction, and maritime, OSHA currently has an 8-hour TWA limit of 200 ppm for 1,2-dichloroethylene; there is no PEL for this substance in agriculture. The ACGIH TLV*-TWA for 1,2-dichloroethylene is 200 ppm. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA limit of 200 ppm for 1,2dichloroethylene in agriculture. This action will make the PEL for this substance consistent across all regulated sectors.

1,2-Dichloroethylene, which is available commercially as a 60:40 mixture of the cis- and trans-isomers, is a colorless liquid with a slightly acrid, ether-like odor (ACGIH 1986, p. 185; Merck 1983, p. 14). It is used as a general solvent for organic materials, for dye extraction, and in perfumes, lacquers, and thermoplastics; it is also used in organic synthesis (Hawley's 1987, p.

1,2-Dichloroethylene causes eye irritation and central nervous system depression in humans and animals. The oral LD50 in rats is 770 mg/kg (RTECS 1990). After 8 minutes of exposure to a 18,000-ppm concentration of the cisisomer, rats became anesthetized; 4 hours of exposure at the same concentration resulted in death. The trans-isomer proved to be twice as potent (Smyth 1956, in Proctor, Hughes, and Fischman 1988, p. 189). Dogs developed reversible superficial corneal opacities when exposed to high vapor concentrations (not further specified)

(Grant 1986, pp. 325-326). Animals of four species (rats, rabbits, guinea pigs, and dogs) exposed to 1,2dichloroethylene for 7 hours/day, 5 days/week for 6 months at 500 or 1000 ppm showed no significant changes in growth, mortality, clinical chemistry, or gross or microscopic examination (Torkelsen 1965, in ACGIH 1986, p. 185). Another study, however, did report effects in rats exposed chronically to a 200-ppm concentration of dichloroethylene (trans-isomer); the liver, lungs, and leukocyte counts of these animals were affected (Clayton and Clayton 1981, p. 3552).

In humans, 1,2-dichloroethylene formerly found use as a general anesthetic (Proctor, Hughes, and Fischman 1988, p. 189). Symptoms of vertigo, nausea, and burning of the eyes were caused in subjects exposed to the trans-isomer at a concentration of 2200 ppm. Prolonged or repeated contact of the skin with dichloroethylene causes defatting and dermatitis (HSDB 1990). Von Oettingen also reported a fatality caused by exposure to very high vapor concentrations (not further specified) in the workplace (von Oettingen 1955, in Proctor, Hughes, and Fischman 1988, p.

Based on this evidence in humans and animals, OSHA preliminarily concludes that 1,2-dichloroethylene causes eye irritation and central nervous system depression in exposed workers and that, in the absence of a PEL, agricultural workers are at significant risk of experiencing these effects. The Agency believes that establishing an 8-hour TWA limit of 200 ppm will substantially reduce these risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. 2,6-di-tert-BUTYL-p-CRESOL CAS: 128-37-0; Chemical Formula:

C15H24O H.S. No. 1117

OSHA has no limit for 2,8-di-tertbutyl-p-cresol (DBPD) in the construction, maritime, or agriculture industries. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed by OSHA. The ACGIH has a TLV®-TWA of 10 mg/m3 for DBPD. OSHA is proposing an 8-hour TWA PEL of 10 mg/m3 for this substance in construction, maritime, and agriculture. This is the limit recently established for DBPD in general industry.

DBPD is a white crystalline compound that is prepared from p-cresol and isobutylene. DBPD is widely used as a food preservative, a gasoline additive, and an ingredient in lubricating oils.

waxes, rubbers, paints, plastics, and elastomers (ACGIH 1988, p. 227).

DBPD is an irritant of the eyes and mucous membranes; in animals, exposure to this substance has also caused lung and liver injury. The oral LD₅₀ ranges from 0.89 g/kg in rats to 10.7 g/kg in guinea pigs (RTECS 1990). Applied to the skin of rabbits, DBPD caused moderate skin irritation, and instillation into the eyes of these animals also caused a moderate degree of eye irritation (RTECS 1990). One year of daily oral administration of 0.17 to 0.9 g/kg produced no effects in dogs, and 2 years of daily oral administration of 0.2, 0.5, or 0.8 percent DBPD also had no effects in rats (Deichmann, Clemmer, Rakoczy, Bianchine et al. 1955/Ex. 1-505). Some growth rate decreases and liver weight increases were demonstrated in rats fed 0.01 to 0.5 percent DBPD (total daily diet) for periods ranging from 12 days to 80 weeks (Brown, Johnson, and O'Halloran 1959/Ex. 1-621; Creaven, Davies, and Williams 1966/Ex. 1-547). These animals also exhibited reversible activation of microsomal liver enzymes. One study in pregnant rats fed DBPD showed teratogenic effects in the offspring, but other research has failed to confirm these results (Grant 1986, p. 164). Some carcinogenicity studies have suggested that DBPD may have a promoting effect; other bioassays have shown no carcinogenic effects. Rats and mice fed DBPD at doses of 3000 or 6000 ppm for 105 to 108 weeks did not show an increased tumor incidence compared with controls (NCI 1979, in HSDB 1989). Administration of DBPD following dosing with a known carcinogen (acetylaminofluorene or urethane) caused an increased incidence of tumors (hepatomas and pulmonary adenomas) (Klaassen, Amdur, and Doull 1986, p. 134). Another study in rats given DBDP after acetylaminofluorene reports that these animals developed bladder cancer (Klaassen, Amdur, and Doull 1986, p. 1118). The no-effect dietary level for DBPD in rats is 25 mg/kg (Gilbert and Golberg 1965/Ex. 1-902).

In humans, exposure to di-tert-butyl-pcresol causes skin irritation and may cause dermal sensitization (Klaassen, Amdur, and Doull 1986, p. 65). A 48-hour test in human subjects showed that the irritant ocular dose for this period was 500 mg of DBDP (RTECS) 1990). No other information on DBDP's effects in humans is available.

Based on this evidence, OSHA is proposing an 8-hour TWA limit of 10 mg/m3 for 2,6-di-tert-butyl-p-cresol. The Agency preliminarily concludes that this limit will protect workers in

construction, maritime, and agriculture against a significant risk of sensory irritation, which is a material health impairment. OSHA believes that the proposed limit is necessary to reduce this significant risk substantially. In addition, promulgation of the proposed limit will make the PEL for DBPD consistent across all regulated sectors. DIETHANOLAMINE

CAS: 111-42-2; Chemical Formula: HO(CH₂)₂NH(CH₂)₂OH H.S. No. 1134

OSHA has no limit for diethanolamine in the construction, maritime, or agriculture industries. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. The ACGIH has an 8-hour TLV*-TWA of 3 ppm for this substance. OSHA is proposing an 8-hour TWA PEL of 3 ppm for diethanolamine; this is the limit recently established in general industry.

Diethanolamine is a solid or a liquid, depending on temperature; it has an ammonia-like odor. Diethanolamine is used to make cosmetics, cleaners, detergents, emulsifiers, dispensing agents, and alkalizing agents (Proctor, Hughes, and Fischman 1988, p. 198).

Diethanolamine is an irritant on acute exposure and a liver and kidney toxin on chronic exposure. The oral LD50 in rats is 710 mg/kg, and the dermal LD50 in rabbits is 12,200 mg/kg (RTECS 1990). Instilled into rabbit eyes, diethanolamine caused severe irritation, although skin contact caused only mild irritation in the same species (RTECS 1990). Rats given 100 or 500 mg/kg by interperitoneal injection showed cytoplasmic vacuolization of the liver and kidneys and, at the high dose, tubular degeneration of the kidneys (Grice et al. 1971, in Food Cosmet. Toxicol. 9:847). Rats fed diethanolamine at a dose of 0.17 g/kg for 90 days showed cloudy swelling and degeneration of the kidney tubules and fatty degeneration of the liver (Proctor, Hughes, and Fischman 1988, p. 198; Smyth, Carpenter, and Weil 1951/Ex. 1-439). Dietary studies in rats showed no ill effects after 90 days of feeding at 20 mg/kg/day (Smyth, Carpenter, and Weil 1951/Ex. 1-439)

In humans, diethanolamine has caused mild eye and nose irritation (HSDB 1989). Splashed into the eye, this substance may cause severe pain, irritation, and corneal damage (Rumack Poisindex). In contact with the skin, moderate irritation may develop (Rumack Poisindex).

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 3 ppm for diethanolamine. The Agency preliminarily concludes that this limit will protect workers in construction, maritime, and agriculture from the significant risks of eye damage and skin irritation associated with exposure to this substance. OSHA considers these effects material health impairments and believes that the proposed limit is necessary to reduce these risks substantially. In addition, promulgation of this limit will make the PEL for diethanolamine consistent across all regulated sectors.

DIETHYL PHTHALATE
CAS: 84–66–2; Chemical Formula:
C₆H₄(COOC₂H₅)₂
H.S. No. 1136

OSHA has no limit for diethyl phthalate in the construction, maritime, or agriculture industries. NIOSH has no REL but concurs (Ex. 8–47, Table N1) with the proposed limit. The ACGIH has a TLV*-TWA of 5 mg/m³ for this substance, and OSHA is proposing 5 mg/m³ as an 8-hour TWA. This is the limit recently established for diethyl phthalate in general industry.

Diethyl phthalate is an oily colorless liquid with no odor. It is used in insecticidal sprays, as a mosquito repellant, a solvent, a plasticizer, a wetting agent, a camphor substitute, and as an alcohol denaturant (ACGIH 1986, p. 200; Genium MSDS 1987, No. 435; Hawley's 1987, p. 394). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide

Act (FIFRA) Diethyl phthalate causes irritation of the eyes, skin, and mucous membranes and central nervous system effects. The oral LD50 in rats is 8600 mg/kg (RTECS 1990). Diethyl phthalate is readily absorbed through the skin; about onefourth of a 30 to 40 mg/kg dose of radiolabelled diethyl phthalate applied to the skin of rats appeared in the urine of exposed rats 24 hours after application of the dose (Elsis et al. 1989). Guinea pigs exposed to diethyl phthalate at a concentration of 511 ppm for 6 hours showed signs of mild skin irritation (Clayton and Clayton 1982, p. 2347). Cats exposed to 10 mg/m3 for 5 hours showed signs of nasal irritation (Clayton and Clayton 1982, p. 2347). Rats fed diethyl phthalate showed decreases in testosterone concentrations and testicular atrophy (Oishi and Hiraga 1980, in Toxicol. Appl. Pharmacol. 53(1):35-41). In several species of experimental animals, central nervous system depression is a common effect of intraperitoneal and intravenous administration of diethyl phthalate (Cralley 1966, in J. Pharmaceut. Sci. 55:158-162). The results of reproductive

studies conducted on diethyl phthalate have been inconclusive. In one study. pregnant Sprague-Dawley rats were given intraperitoneal injections of diethyl phthalate on days 5, 10, and 15 of gestation at doses of 0.506, 1.012 or 1.686 ml/kg. Some fetal resorptions occurred among rats given the low or high dose. but not among rats given the middle dose. All three dose levels produced skeletal malformations in offspring; no other abnormalities were noted (Singh et al., J. Pharmaceut. Sci. 61:51-55, as cited in HSDB 1986). Another study found no adverse effects on fetal growth. viability, or development among CD rats fed 198, 1909, or 3214 mg/kg per day during days 6 through 15 of gestation (Price et al. 1989); however an increased incidence of extra ribs occurred among offspring of rats given maternally toxic doses of diethyl phthalate.

In humans, exposure to diethyl phthalate causes sensory irritation and central nervous system effects. The lowest toxic inhalation concentration in humans is 1000 mg/m3 (RTECS 1990). A study of workers exposed to a mixture of diethyl phthalate, dibutyl phthalate. and di-2-ethyl hexyl phthalate vapors in air at concentrations of 8 to 53 mg/m3 resulted in findings of no phthalates in the blood (before or after the exposure) and no peripheral polyneuritis (Raleigh, personal communication, as cited in ACGIH 1986/Ex. 1-3, p. 200). Fassett (1963a, as cited in ACGIH 1986/Ex. 1-3. p. 200) reported transient nasal and throat irritation produced by exposure to the heated vapors of diethyl phthalate, but no cumulative effects have been noted. A Soviet study of workers (employed between 0.5 to 19 years) who were exposed to several phthalate plasticizers (e.g., butyl phthalate, the higher aryl phthalates. dioctyl phthalate, and benzyl butyl phthalate), as well as to sebacates, adipates, and tri-o-cresyl phosphate at concentrations ranging from 1.7 to 66 mg/ms, reported that there were complaints of pain, numbness, and spasms in the upper and lower extremities. These complaints were related to the duration of exposure and usually began after the sixth or seventh year of employment (Milkov, Aldyreva. Popova et al. 1973/Ex. 1-646). These investigators reported polyneuritis in 32 percent of the 47 persons examined for this health effect; of 81 persons evaluated for vestibular dysfunction, 78 percent showed depression of vestibular receptors (Milkov, Aldyreva, Popova et al. 1973/Ex. 1-646).

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 5 mg/ m³ for diethyl phthalate. The Agency preliminarily concludes that this limit will protect workers in construction, maritime, and agriculture against the significant risks of polyneuritis and vestibular dysfunction that are potentially associated with occupational exposure to this substance.

Promulgation of this limit will substantially reduce these significant risks and make OSHA's PEL for this substance consistent across all regulated sectors.

DINITOLMIDE (3,5-DINITRO-O-TOLUAMIDE)

CAS: 148-01-6; Chemical Formula: C₆H₇N₃O₈ H.S. No. 1144

OSHA has no limit for dinitolmide in construction, maritime, or agriculture. NIOSH has no REL but concurs (Ex. 8–47, Table N1) with the selection of this PEL. The ACGIH has a TLV*-TWA of 5 mg/m³ for this substance, and OSHA is proposing 5 mg/m³ as an 8-hour TWA PEL. This is the limit recently established for this substance in general industry.

Dinitolmide, which is also called 3,5-dinitro-o-toluamide, is a yellowish solid. This substance is used as a coccidiostat and a food additive (ACGIH 1986, p. 218; Hawley's 1986, p. 1262). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide

Act (FIFRA).

Dinitolmide causes liver and blood effects in animals. The oral LD50 in rats is 600 mg/kg (RTECS 1990). In rats fed 6 mg/kg/day dinitolmide for 2 years, increases in liver weight occurred in females, and fatty changes were observed in the livers of both males and females at autopsy (Dow Chemical Company 1973e, as cited in ACGIH 1986, Ex. 1-3, p. 213). No adverse effects were seen either in rats fed 3 mg/kg/day for 2 years or in dogs fed on the same regimen at a dose of 10 mg/kg/day (Dow Chemical Company 1973e, in ACGIH 1986/Ex. 1-3, p. 213). Rats exposed to 150 mg/kg developed methemoglobinemia (Gosselin, Smith, and Hodge 1984, p. II-389). Dinitolmide is mutagenic in bacterial test systems (RTECS 1990).

No systemic effects of dinitolmide exposure have been reported in humans. Allergic contact dermatitis has been reported in workers handling animal feed that contained dinitolmide (Fischer

1975, in Cutis 2:701-702).

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 5 mg/m³ for dinitolmide. The Agency preliminarily concludes that this limit will protect workers in construction,

maritime, and agriculture industries from the significant risk of dermatitis and systemic changes that are potentially associated with exposure to this substance. OSHA considers these effects material health impairments and believes that the proposed limit is necessary to reduce these risks substantially. In addition, promulgation of this limit will make the PEL for dinitolmide consistent across all OSHA-regulated sectors.

DIPHENYLAMINE
CAS: 122-39-4; Chemical Formula:
(C₀H₀)₂NH
H.S. No. 1147

OSHA's limit for diphenylamine in construction, maritime, and general industry is 10 mg/m³ as an 8-hour TWA. There is no limit for this substance in agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the proposed limit. The ACGIH recommends a TLV*-TWA of 10 mg/m³ for this substance, and OSHA is proposing 10 mg/m³ as an 8-hour TWA for diphenylamine in agriculture. Promulgation of this PEL will make OSHA's limit for this substance consistent across all regulated sectors.

Diphenylamine is a colorless solid that takes the form of monoclinic leaflets that discolor when exposed to light; it has a floral-like odor.

Diphenylamine is used as a stabilizer for plastics, nitrocellulose explosives, and celluloids, and in the manufacture of pesticides, pharmaceuticals, and dyes. It is also used in antioxidants (ACGIH 1986, p. 220; Sittig 1985, p. 1885). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide

Act (FIFRA).

Diphenylamine is a liver and kidney toxin and has caused adverse developmental effects in animals. The oral LD50 in guinea pigs is 300 mg/kg (RTECS 1990). This substance is known to be absorbed through the skin, but no dermal toxicity data are available. Animals acutely poisoned by oral administration develop anorexia, diarrhea, excitability, hypothermia, emaciation, and generalized weakness before death, which may be delayed for 2 to 3 weeks (Gosselin, Smith, and Hodge 1984, p. II-209). In cats, acute poisoning is associated with methemoglobinemia. Animals exposed to diphenylamine dust at unspecified concentrations showed changes in the liver, spleen, and kidneys at autopsy (Robert et al. 1937, in ACGIH 1986, p. 220). Dietary studies of rats fed 0.025, 0.1, 0.5, 1.0, or 1.5 percent diphenylamine for 226 days demonstrated nonmalignant

renal cysts in animals fed at the three highest doses (Thomas, Cox, and Deeds 1957/Ex. 1-873). Rats fed diphenylamine crystals encapsulated in collodion developed bladder papillomas within 125 days (Yoshida, Shimauchi, and Kin 1941, as cited in ACGIH 1986/Ex. 1-3, p. 220). Mice gavaged with diphenylamine showed kidney damage involving the tubules and glomeruli; liver effects were also seen (Kronevi and Holmberg 1979, in Exp. Pathol. (Jena) 17(2):77-81). Fed to pregnant rats at a dose of 7500 mg/kg on days 17 through 22 of pregnancy diphenylamine caused urogenital system abnormalities (polycystic kidneys) in the offspring (Klaassen, Amdur, and Doull 1986, p. 326).

In humans, exposure to diphenylamine may cause eye and mucous membrane irritation, dermatitis. bladder symptoms, and an increase in heart rate (Hazardous Substance Fact Sheet 1985). Acute overexposure may also cause methemoglobinemia (Genium MSDS 1989). A report of industrial diphenylamine poisoning in France described bladder symptoms, tachycardia, hypertension, and eczema in overexposed workers (Fairhall 1957g, as cited in ACGIH 1986/Ex. 1-3, p. 220). Diphenylamine has been linked in epidemiological studies (Orjelick 1975: in Intl. Occ. Hlth. Safety 44(5):46-47; Parkes and Evans 1984, in C.E. Searle, ed. Chemical Carcinogens, 2nd ed.) to the development of bladder cancer in exposed workers, although contamination by 2-naphthylamine, a recognized human carcinogen, may have been the cause of these tumors.

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 10 mg/ m3 for diphenylamine in agriculture. The Agency preliminarily concludes that this limit will protect workers in this sector against the significant risks of liver. kidney, cardiovascular, and other systemic effects, all of which constitute material health impairments that are potentially associated with exposures to this substance. Because the proposed limit is identical to the PEL recently established for diphenylamine in general industry and currently in effect in construction and maritime, promulgation of the proposed PEL in agriculture will make OSHA's limit for diphenylamine consistent across all regulated sectors.

DIURON

CAS: 330-54-1; Chemical Formula: C₉H₁₀Cl₂N₂O H.S. No. 1153

OSHA has no limit for diuron in construction, maritime, or agriculture. NIOSH has no REL but concurs (Ex. 8– 47, Table N1) with the limit being proposed. The ACGIH has a TLV*-TWA of 10 mg/m³ for diuron. OSHA is proposing an 8-hour TWA PEL of 10 mg/ m³ for diuron; this is the limit recently established for this substance in general industry.

Diuron is a white, crystalline, odorless substance. Diuron is a pre-emergence herbicide that is widely used as an industrial area weed control agent, an herbicide for railroad rights of way, and an agricultural herbicide (HSDB 1990). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Diuron is an irritant of the skin and mucous membranes. In animals, chronic exposure may cause growth retardation. anemia, and enlargement of the spleen and liver. This substance may also be teratogenic in animals. The oral LD50 in rats is 1017 mg/kg (RTECS 1990). The dermal LD50 in rabbits is greater than 2500 mg/kg (Taylor 1976b, in EPA 1987). Acutely poisoned animals showed signs of central nervous system depression before death (EPA 1987: Health Advisory). Applied to the abraded skin of guinea pigs, diuron caused moderate irritation (DuPont n.d., in ACGIH 1986, p. 228). Instilled into the eyes of rabbits, however, diuron caused no irritation (Larson and Schaefer 1976, in EPA 1987). Rats fed 50 to 5000 ppm diuron for 90 days showed the following effects: no changes at 50 ppm, reduced weight gain in females only at 500 ppm, and reduced body weight, enlarged spleens, and chronic methemoglobinemia in rats of both sexes (Hodge et al. 1967). Rats fed 25 to 2500 ppm diuron for 2 years showed the following effects: no effects at 25 ppm, abnormal blood pigment in some animals at 125 ppm, and hematological changes, growth depression, hemosiderosis of the spleen, and increased mortality at 2500 ppm (Hodge et al. 1946b, 1967). Administered to pregnant rats on days 6 through 15 of gestation, diuron caused a statistically significant increase in the incidence of wavy ribs and delayed ossification in the offspring at doses of 250 mg/kg or greater (Khera et al. 1979). In another experiment, administration of diuron to pregnant rats on days 15 and 22 of pregnancy caused reductions in maternal body weight and in mean fetal weights and an increase in the number of anomalous fetuses [Khera et al. 1979]. In 2-year feeding studies in rats and dogs, the no-effect levels were reported to be 250 and 125 ppm, respectively. A diuron concentration of 125 ppm in the diet did not cause reproductive or carcinogenic effects in a threegenerational study of rats (Hodge, Downs, Panner et al. 1967/Ex. 1–911; Hodge, Downs, Smith et al. 1968/Ex. 1– 912); a dietary level of 1400 ppm did not have carcinogenic effects in mice (Innes, Ulland, Valerio et al. 1969/Ex. 1–270).

In humans, exposure to diuron causes irritation of the eyes, nose, and skin (Hayes 1982, p. 541). A woman who intentionally ingested an herbicidal formulation that contained 46 percent diuron and 30% amitrole survived and had no sequelae (Hayes 1982, p. 154).

Based on this evidence in humans and animals, OSHA is proposing an 8-hour TWA limit of 10 mg/m3 for diuron. OSHA preliminarily concludes that this limit will protect workers in construction, maritime, and agriculture from the significant risks potentially associated with occupational exposure to this substance at the levels permitted by the absence of an OSHA PEL. These risks include both skin and respiratory tract irritation, which constitute material impairments of health. The Agency believes that the proposed limit is necessary to reduce these risks substantially. In addition, promulgation of the proposed PEL will make OSHA's limit for diuron consistent across all OSHA-regulated sectors.

ENDRIN

CAS: 72-20-8; Chemical Formula: C₁₂H₈Cl₆O H.S. No. 2073

In general industry, construction, and maritime, OSHA's current permissible exposure limit for endrin is an 8-hour TWA of 0.1 mg/m3, with a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. OSHA has no PEL for endrin in agriculture. The 1987-1988 ACGIH TLV®-TWA for this substance is 0.1 mg/ms, with a skin notation. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the PEL being proposed. OSHA is proposing a PEL of 0.1 mg/m3, and a skin notation, for endrin in agriculture. Promulgation of this limit will make the PEL for endrin consistent across all OSHA-regulated sectors.

Endrin, which is the stereoisomer of dieldrin, is a white, non-flammable, crystalline powder. Endrin was formerly used as an insecticide, avicide, and rodenticide. Its manufacture and use has been discontinued in the United States (ACGIH 1986, p. 231; Proctor, Hughes, and Fischman 1988, p. 222). OSHA is proposing a limit for endrin in agriculture both to ensure consistency in PELs across sectors and to provide protection for workers in agriculture in the unlikely event that this substance is

once again permitted for use as a pesticide.

Endrin causes convulsions in humans and reproductive and developmental effects in animals. The oral LD,00 in rats, mice, and monkeys are 3 mg/kg, 1.37 mg/kg, and 3 mg/kg, respectively (RTECS 1990). The dermal LD50 in rabbits is 60 mg/kg (RTECS 1990). Following a 1-hour inhalation exposure to approximately 2000 mg/m3 of endrin. 3 of 10 rats died (Anderson et al. 1953; Hine, Ungar, Anderson et al. 1954, in ACGIH 1986, p. 231). Rats and mice inhaling sublimed endrin at a concentration of 0.36 ppm (15 mg/m3) for 7 hours/day, 5 days/week for 26 weeks exhibited no signs of intoxication or growth retardation; however, two of four rabbits died under these exposure conditions (Treon et al. 1955, in ACGIH 1986, p. 231). Rats given oral doses of 2.32 mg/kg of endrin on the fourth day of pregnancy showed signs of reproductive effects, and the offspring had developmental abnormalities (RTECS 1990). Chernoff et al. reported an increased incidence of fused ribs and meningoencephaloceles among the young of hamsters given a single dose of up to 10 mg/kg endrin on day 8 of pregnancy; no deaths were reported in dams or young (Chernoff 1979, in Hayes 1982, p. 248). An oral dose of 7 mg/kg endrin on day 8 of pregnancy caused reproductive effects in the dams and embryotoxic and developmental effects in the offspring (RTECS 1990).

In humans, endrin intoxication often causes an epileptiform convulsion that occurs from 30 minutes to 10 hours after exposure, lasts for several minutes, and is followed by stupor (Jager 1970; Coble et al. 1967, in Proctor, Hughes, and Fischman 1988, p. 222). The signs and symptoms of endrin intoxication in humans include headache, dizziness, leg weakness, nausea, insomnia, and, occasionally, slight mental confusion (Jager 1970, in Proctor, Hughes, and Fischman 1988, p. 222; Hayes 1982, pp. 247-251). An oral dose in the range of 0.2 to 0.25 mg/kg produces convulsions in humans (Diechmann 1973, in ACGIH 1988, p. 231). In cases of severe endrin poisoning, repeated violent convulsions can occur (Hayes 1982, p. 249). Recovery is rapid in most cases, but symptoms such as headache, dizziness, lethargy, weakness, and anorexia may persist for 2 to 4 weeks (Coble et al. 1987, in Proctor, Hughes, and Fischman 1988, p. 222). Brain stem injury was evident in the encephalograms of 20 percent of endrin manufacturing and formulating workers; 3.3 percent of these workers had experienced epileptiform seizures (NRC 1977, in HSDB 1985). In England,

endrin poisoning occurred in more than 100 people who had eaten bread made from flour contaminated with this substance. One to 3 hours after ingestion, the most affected patients lost consciousness; other victims experienced convulsions, violent muscular contractions, and periods of unconsciousness. All patients were ill for several days but subsequently recovered (Gosselin, Smith, and Hodge

1984, p. 285).

Based on this evidence in humans and animals, OSHA preliminarily concludes that endrin causes convulsions and central nervous system effects in exposed individuals. OSHA preliminarily finds that, in the absence of a limit for endrin, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that the proposed limit of 0.1 mg/m3 as an 8-hour TWA, and the skin notation, will substantially reduce these risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. L.P.G. (Liquefied Petroleum Gas) CAS: 68476-85-7; Chemical Formula:

Mixture of C3H5 and C4H10 H.S. No. 2099

The OSHA PEL for liquefied petroleum gas (L.P.G.) in general industry, construction, and maritime is 1000 ppm as an 8-hour TWA. The Agency has no PEL for L.P.G. in agriculture. The ACGIH TLV®-TWA for this substance is 1000 ppm. NIOSH has no REL for L.P.G. but concurs with the PEL being proposed (Ex. 8-47, Table N3A). OSHA is proposing a PEL of 1000 ppm as an 8-hour TWA for L.P.G. in agriculture. Promulgation of this limit will make the PEL for L.P.G. consistent across all OSHA-regulated sectors.

L.P.G. is a mixture of propane and butane and is a flammable, explosive, colorless gas (or liquid under pressure). L.P.G. is a byproduct of petroleum refining. It may contain isomers and often has a foul-smelling odorant added to it to increase its odor warning properties. It is used primarily as a fuel, refrigerant, and propellant and in organic synthesis. L.P.G. is also used in the flame control of weeds and in metal cutting (ACGIH 1986, p. 350; Hazardous Substance Fact Sheet 1986, p. 6; HSDB 1986, "Butane;" HSDB 1988, "Propane").

L.P.G. is non-toxic at low concentrations; at very high concentrations, it causes central nervous system depression and, if exposures are high enough, asphyxiation. Cats exposed to L.P.G. at an 89-percent concentration (890,000

ppm) experienced a depression in blood pressure (HSDB 1988, "Propane") Guinea pigs exposed to a 2.4 to 5.5 percent (24,000 to 55,000 ppm) concentration of propane (the major component of L.P.G.) showed dyspnea at the lower concentrations and tremor, nausea, retching, and stupefaction at the higher concentration (HSDB 1988, "Propane"). L.P.G. does not cause eye irritation or damage, even when injected into the anterior chamber of the rabbit eye (Grant 1986, p. 207). Pregnant mice exposed to L.P.G. at a concentration of 5 to 8 percent (50,000 to 80,000 ppm) for 1 hour on the eighth day of gestation delivered hydrocephalic offspring (HSDB 1988, "Propane").

In humans, the inhalation of a 10,000ppm concentration of butane (a major component of L.P.G.) for 10 minutes may cause drowsiness (Patty and Yant 1929, in Clayton and Clayton 1981, p. 3182). Five workers exposed to propane, another major component of L.P.G., experienced headache, numbness, vomiting, and a feeling of being chilled (HSDB 1988, "Propane"). Acute exposure to propane at a 250-, 500-, or 1000-ppm concentration for 1 minute to 8 hours caused no effects in volunteers (HSDB 1988, "Propane"). Contact of the skin with pressurized (liquefied) L.P.G. may cause frostbite and skin burns (Clayton and Clayton 1981, p. 3182).

Based on this evidence, OSHA is proposing a 1000-ppm 8-hour TWA limit to protect workers in agriculture from the significant risk of central nervous system depression potentially caused by exposure to L.P.G. at the concentrations possible in the absence of an OSHA PEL. The Agency preliminarily concludes that this limit is necessary to reduce substantially a significant risk of material health impairment in exposed agricultural workers. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. METHYL ACETATE CAS: 79-20-9; Chemical Formula:

CH3COOCH3 H.S. No. 1249

OSHA's current 8-hour TWA limit for methyl acetate in construction and maritime is 200 ppm; there is no PEL in agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limits being proposed. The ACGIH has an 8-hour TLV*-TWA of 200 ppm and a TLV®-STEL of 250 ppm for methyl acetate. OSHA is retaining the 8-hour TWA PEL of 200 ppm and proposing to add a 15-minute STEL of 250 ppm in construction and maritime and is also proposing to extend these limits to agriculture. These are the limits recently established for methyl acetate in general industry.

Methyl acetate is a highly volatile. colorless liquid with a pleasant, fruity odor. This substance is used as a solvent in lacquers and paint removers. and as an ingredient in pharmaceuticals. Methyl acetate is also used in agriculture to destroy cocklebur seeds (Clayton and Clayton 1981, p. 2271).

Methyl acetate is an irritant of the eyes, mucous membranes, and respiratory tract; at high concentrations. it is a narcotic. The oral LD50 in rats is 5450 mg/kg, and the lowest lethal concentration in the same species is 32,000 ppm for 4 hours (RTECS 1990). Applied to the skin or eyes of rabbits, methyl acetate caused a moderate degree of irritation (RTECS 1990). Cats exposed to a 5000-ppm concentration of methyl acetate for 20 minutes showed signs of eye irritation; exposure to 10,000 ppm for 10 hours caused narcotic effects, and exposure to 18,480 ppm for 4 to 4.5 hours caused dyspnea, convulsions, vomiting, and narcosis (Clayton and Clayton 1981, p. 2272). Cats exposed for 6 hours/day for 8 days to a methyl acetate concentration of 6600 ppm lost weight, became weak, and recovered from the exposure slowly (Clayton and Clayton 1981, p. 2272).

In humans, exposure to methyl acetate at a concentration of 15,000 mg/m3 (approximately 5000 ppm) causes eye and upper respiratory tract irritation; when the concentration is increased to 10,000 ppm, the irritation persists after exposure ceases (Clayton and Clayton 1981, p. 2272). A worker who inhaled an unspecified concentration of methyl acetate developed dizziness, headache, and other signs of central nervous system depression, as well as blindness caused by atrophy of the optic nerve (Lund 1944, in J. Ind. Hyg. Toxicol. 28:35). The atrophy may have been caused by hydrolysis of the methyl acetate to methanol (AIHA 1964). Longterm contact of this substance with the skin causes defatting and dermatitis (Proctor, Hughes, and Fischman 1988, p.

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 200 ppm TWA and a 15-minute STEL of 250 ppm for methyl acetate in the construction, maritime, and agriculture industries. OSHA believes that the proposed limits are necessary to reduce substantially the significant risk of eye. skin, and respiratory tract irritation, and of narcosis, that is associated with exposure to methyl acetate. The Agency considers these adverse effects material impairments of health. Promulgation of these limits will also make OSHA's

PELs for methyl acetate consistent across all regulated sectors. METRIBUZIN CAS: 21087-64-9; Chemical Formula: CsH14N4OS

C₈H₁₄N₄OS H.S. No. 1275

OSHA has no limit for metribuzin in the construction, maritime, and agriculture industries. The ACGIH has a TLV*-TWA of 5 mg/m³ for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 5 mg/m³ for metribuzin. This is the limit recently established for this substance in general industry.

Metribuzin is a crystalline solid that has a slight musty odor and is used as a selective herbicide. When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide

Act (FIFRA).

Metribuzin is a mild irritant of the eyes and skin in experimental animals. The oral LDso in rats is 1100 mg/kg, and the dermal LDso in the same species is 2 g/kg (RTECS 1990). The LCso in rats for a wettable granular formulation of metribuzin (concentration not specified) is greater than 20 mg/liter for 1 hour (Mobay MSDS 1985). In contact with the eyes or skin of rabbits, metribuzin caused a mild degree of irritation (Mobay MSDS 1985; EPA 1987, ODW Health Advisory). Rats were fed metribuzin for 3 months at doses of 2.5, 7.5, 25, or 75 mg/kg/day; enlarged thyroid glands were seen in the two high-dose groups, and females in the three highest dose groups also had enlarged livers (Loser et al. 1969, in EPA 1987). Female mice were fed metribuzin for 24 months at doses of 30, 120, or 480 mg/kg/day; those in the high-dose group developed increased liver and kidney weights (Hayes et al. 1981, in EPA 1987). No sensitizing effects were seen in skin tests of guinea pigs, and a skin application of the 70-percent wettable powder of 1000 mg/kg per day for three weeks produced no effects in rats (Deutsche Forschungsgemeinschaft 1981, as cited in ACGIH 1986/Ex. 1-3, p. 411). A no-effect level of 100 ppm was observed in a two-year dietary study of rats and dogs (Deutsche Forschungsgemeinschaft 1981, as cited in ACGIH 1986/Ex. 1-3, p. 411); these same investigators observed no teratogenic, embryotoxic, or reproductive effects in rats or rabbits. In a subacute inhalation study in rats, exposure to a concentration of 31 mg/m3 caused no observed effects (ACGIH 1986, p. 411, Ex. 1-3). In Chinese

hamsters and mice, no mutagenic activity was observed (Siebert and Lemperle 1974/Ex. 1–689).

No human poisonings have been linked to metribuzin. In long-term oral studies in volunteers, the highest no-observed-effect levels (NOELs) were 2.5 to 5 mg/kg per day (ACGIH 1986/Ex. 1-3, p. 411). Single and repeated patch tests in humans did not show sensitization (Deutsche Forschungsgemeinschaft 1981, as cited in ACGIH 1986/Ex. 1-3, p. 411).

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 5 mg/ m3 for metribuzin in the construction, maritime, and agriculture sectors. The Agency preliminarily concludes that this limit is necessary to protect workers in these sectors against the significant risks of metabolic and central nervous system effects that are potentially associated with occupational exposure to metribuzin. The Agency considers these adverse effects material impairments of health and believes that the proposed limit will substantially reduce these risks. Promulgation of this PEL will also make OSHA's limit for metribuzin consistent across all regulated sectors.

1-NITROPROPANE
CAS: 108-03-2; Chemical Formula:
CH₂CH₂CH₂NO₂
H.S. No. 2121

OSHA's permissible exposure limit for 1-nitropropane in general industry, construction, and maritime is 25 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 25 ppm for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA limit of 25 ppm for 1-nitropropane in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

1-Nitropropane is a colorless liquid with a mild, fruity odor. This substance is used as a solvent, chemical intermediate, rocket propellant, and gasoline additive (Hawley's 1987, p. 832; NIOSH/OSHA Occupational Health Guideline 1981, p. 1).

1-Nitropropane causes primary irritation in humans and animals; in animals, exposure to this substance also causes damage to the liver and kidneys. The oral LD₅₀s in rats and mice are 455 mg/kg and 800 mg/kg, respectively (RTECS 1987). The LC₅₀ in rats is 3100 ppm for 8 hours (RTECS 1987). Rabbits survived a 1-hour exposure to a 1-nitropropane concentration of 10,000 ppm but died from exposure to a 5000-ppm concentration for 3 hours (Machle,

Scott, and Treon 1940, in ACGIH 1986, p. 377). Acutely poisoned animals showed the following signs and symptoms: conjunctival irritation, lacrimation, slow respiration with some rales. incoordination, ataxia, and weakness. Autopsy of acutely poisoned rabbits revealed severe fatty infiltration of the liver and moderate kidney damage (Machle, Scott and Treon 1940, in Proctor, Hughes, and Fischman 1988, p. 377). In rats exposed to a 100-ppm concentration of 1-nitropropane 7 hours/ day, 5 days/week for up to 21 months, no systemic effects were observed (Griffin, Stein, and Coulston 1980, in ACGIH 1986, p. 440).

Human volunteers reported that exposure to concentrations above 100 ppm caused irritation after brief but not further specified periods of exposure (Silverman, Schulte, and First 1946, in Clayton and Clayton 1982, p. 4161), and exposure to a 150-ppm concentration of 1-nitropropane for 15 minutes caused eye irritation (RTECS 1987). The symptoms of chronic overexposure to 1-nitropropane include headache and nausea (Clayton and Clayton 1982, p. 4161).

Based on this evidence in humans and animals, OSHA preliminarily concludes that 1-nitropropane is a sensory irritant and also causes possible liver and kidney injury. OSHA believes that, in the absence of a limit for this substance, workers in agriculture are at significant risk of experiencing these effects. Establishing an 8-hour TWA PEL of 25 ppm is thus necessary to reduce substantially the risk of these material health impairments, Promulgation of this limit will also make the PEL for 1-nitropropane consistent across all OSHA-regulated sectors.

OIL MIST (MINERAL) CAS: 8012–95–1; Chemical Formula: None

H.S. No. 1297

OSHA's limit for oil mist is 5 mg/m³ as an 8-hour TWA in construction, maritime, and general industry. There is no limit in agriculture. The ACGIH has a 5-mg/m³ TLV°-TWA and a 10 mg/m³ TLV°-STEL for oil mist (mineral). NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 5 mg/m³ for oil mist. This is the limit recently established for this substance in general industry.

Oil mist is the airborne mist of petroleum-based cutting oils or of white petroleum oil. The odor of oil mist is described as similar to that of burned lubrication oil, and this substance is a flammable, oily, colorless liquid (Clayton and Clayton 1981, p. 3396). Mineral oils are used as lubricants and cutting oils.

Oil mist causes eye, skin, and respiratory tract irritation in animals and dermatitis and respiratory effects in exposed workers. If inhaled in sufficient quantities, oil mist can cause lipid pneumonitis (Cralley and Cralley 1985, p. 177). The oral LD50 in mice is 22 g/kg (RTECS 1990). In prolonged contact with the eyes or skin of rabbits, mineral oil causes mild irritation (RTECS 1990). Studies in animals have shown that repeated six-hour daily exposures to 5 mg/m3 caused no adverse effects (Wagner, Wright, and Stokinger 1964, as cited in ACGIH 1986/Ex. 1-3, p. 449). At 100 mg/m³, slight changes, including lung effects, were observed in exposed animals (Lushbaugh, Green, and Redemann 1950/Ex. 1-792). Dogs, rabbits, mice, and gerbils were exposed to 5 or 100 mg/m3 mineral oil mist 6 hours/day, 5 days/week for 2 years; microgranulomas developed only in the dogs and rats (Stula and Kwon 1978, in AJIHA 39(5):393-399).

In humans, exposure to oil mist in the industrial setting has been associated with dermatitis and respiratory effects. A single case of lipid pneumonitis has been reported in a worker exposed to high (not further specified) concentrations of oil mist for 17 years (Proudfit, Van Orstrand, and Miller 1950, in AMA Arch. Ind. Hyg. Occup. Med. 1:105). A metal-polishing mechanic whose skin was repeatedly exposed to mineral oil developed chronic eczema on his hands, forearms, and neck that lasted for 2 years (Sakakibara, Kawabe, Mizuno 1989, in Contact Dermatitis 20(4):291-294). Results of photopatch testing in this worker were positive, indicating that the mineral oil had caused photosensitization dermatitis. Two epidemiological studies in similar populations suggested an association between some mineral oils and cancers of the skin and scrotum (Ex. 426, Ex. 207X, pp. 7-50). A number of scientists believe that these carcinogenic effects were likely to have been caused by contaminants in the oil, such as polycyclic aromatic hydrocarbons and certain additives. Moreover, modern refining techniques have generally eliminated these hazardous substances from mineral oils. OSHA believes that it may be premature to make a judgment on oil mist's carcinogenicity.

Based on this evidence in humans and animals, OSHA is proposing an 8-hour TWA PEL of 5 mg/m³ for mineral oil mist in the construction, maritime, and agriculture industries. The Agency believes that this limit is necessary to

reduce substantially the significant risk of eye, skin, and respiratory tract irritation, pneumonitis, and dermatitis potentially associated with exposure to this substance. OSHA considers all of these adverse effects material health impairments. Promulgation of the proposed limit will also make the PEL for oil mist consistent across all OSHA-regulated sectors.

Note: The 1970 TLV*s listed an entry for "oil mist, vapor"; this entry was deleted at some time prior to the publication of the 1987-88 TLV*s. No entry for "oil mist, vapor" has ever been included on OSHA's Z-tables. Because the term for this substance used by OSHA-oil mist (mineral)-by definition includes the vapor of oil mist, OSHA has determined that keeping the word "vapor" would be redundant and is therefore unnecessary. Accordingly, OSHA's designation of this substance on the new Ztables for construction, maritime, and agriculture is simply "oil mist (mineral)." This decision is consistent with the evaluations undertaken as part of the PEL update process.

PETROLEUM DISTILLATES (NAPHTHA) (RUBBER SOLVENT)

CAS: 8002-05-9; Chemical Formula: None H.S. No. 1312

OSHA has no limit in construction, maritime, or agriculture for petroleum distillates (naphtha), also called rubber solvent. The ACGIH has a TLÝ*-TWA of 400 ppm for petroleum distillates, and NIOSH has a REL of 87 ppm and a 15-minute ceiling of 450 ppm for these substances. OSHA has recently established an 8-hour TWA PEL of 400 ppm in general industry for petroleum distillates, and this is the limit being proposed in construction, maritime, and agriculture. These are the limits recently established for this substance in general industry.

Petroleum distillates (naphtha) are a mixture of hydrocarbons. They are flammable liquids that have a characteristic gasoline-like odor (HSDB 1986). Petroleum distillates are used as solvents and thinners, as a carrier solvent for pesticides, and in gasoline, adhesives, coatings, naphtha soaps, cleaning agents, and in organic synthesis (Hawley's 1987, p. 806; ACGIH 1986, p. 516). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

A study performed by Carpenter, Kinkead, Geary et al. (1975b/Ex. 1–53) exposed rats to concentrations of naphtha between 2800 and 24,200 ppm. Motor incoordination occurred at 5300 ppm, and convulsions and death occurred in all animals at 24,200 ppm. Animals exposed to 480 ppm for 63 days showed no signs of toxicity (Carpenter, Kinkead, Geary et al. 1975b/Ex. 1-53).

NIOSH (1977g, as cited in ACGIH 1986/Ex. 1-3, p. 516) noted that rubber solvent (naphtha) is composed primarily of Co-Co alkanes and, thus, that the limit of 350 mg/m3 (85 ppm) recommended for C6-C8 alkanes should also apply to naphtha. This recommendation presumes that all C5-C8 alkanes possess equivalent neurotoxicity; however, OSHA has preliminarily concluded that not all of the Co-Co alkanes are neuropathic agents. Accordingly, OSHA is proposing an 8-hour TWA PEL of 400 ppm for petroleum distillates in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risk of irritation that is associated with exposure to these substances. OSHA considers such irritation to be a material health impairment. Because the proposed limit is identical to the PEL recently established for petroleum distillates in general industry, promulgation of this limit in construction, agriculture, and maritime will make OSHA's limit for petroleum distillates consistent across all regulated sectors.

m-PHTHALODINITRILE CAS: 626-17-5; Chemical Formula: C₈H₄N₂ H.S. No. 1327

OSHA has no limit for m-phthalodinitrile in construction, maritime, or agriculture. NIOSH has no REL for this substance but concurs (Ex. 8–47, Table N1) with the limit being proposed. The ACGIH has a TLV®-TWA of 5 mg/m³ for m-phthalodinitrile. OSHA is proposing an 8-hour TWA PEL of 5 mg/m³ for m-phthalodinitrile; this is the limit recently established for this substance in general industry.

m-Phthalodinitrile is a white, odorless solid that occurs in the form of needles or powder. It is used as a chemical intermediate for amines, phthalocyanine pigments and dyes, and for high-temperature lubricants and coatings. It is also used to produce phthalate esters (HSDB 1989, Sittig 1985, p. 727).

m-Phthalodinitrile is an irritant of the eyes, mucous membranes, and skin. The oral LD₅₀ in rats is 1860 mg/kg (RTECS 1990). Intraperitoneal administration of lethal doses of this substance caused mice to convulse before death (RTECS 1990). Instilled into the eyes of rabbits, m-phthalodinitrile caused mild irritation (RTECS 1990). In rabbits, slight skin reactions have been reported from dermal applications of m-phthalodinitrile to the intact or abraded

skin for 6 hours/day, 5 days/week over a 3-week period. The doses applied were 0.5, 1.0, or 2.0 g/kg; at the two higher dose levels, some changes in organ (unspecified) size, without histopathologic changes, were observed at autopsy. Female rabbits exposed at the highest dose also lost weight (Owen 1972, as cited in ACGIH 1986/Ex. 1–3, p. 488).

A 15-year review of industrial experience revealed no reports of adverse effects from exposure to mphthalodinitrile (Zeller, Hofmann, Thiess, and Hey 1963, as cited in ACGIH 1986/Ex. 1-3, p. 488). Williams (1959/Ex. 1-1176) attributes this absence of exposure effects to the fact that the aromatic nitriles, of which mpthalodinitrile is one, do not liberate cyanide in the body, as is the case with

the aliphatic nitriles. Based on this evidence, OSHA is proposing an 8-hour TWA limit for mphthalodinitrile of 5 mg/m3 in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers from the significant risk of skin irritation, a material health impairment associated with exposure to m-phthalodinitrile. OSHA believes that the proposed limit is necessary to reduce this risk substantially. In addition, promulgation of the proposed PEL will make OSHA's limit for m-phthalodinitrile consistent across all OSHA-regulated sectors. PLATINUM (METAL)

OSHA has no limit for platinum metal in construction, maritime, or agriculture. NIOSH has no REL for platinum but concurs (Ex. 8-47, Table N1) with the limit being proposed. The ACGIH has a TLV*-TWA of 1.0 mg/m³ for platinum metal (dust). OSHA is proposing an 8-hour TWA PEL of 1 mg/m³ for platinum; this is the limit recently established for this substance in general industry.

CAS: 7440-06-4; Chemical Formula: Pt

H.S. No. 1332

Platinum is a silver-gray, lustrous, malleable, ductile precious metal. It is used in jewelrymaking, electroplating, photography, and dentistry and in the chemical and electrical industries; it is also used in windings for high-temperature furnaces (ACGIH 1986, p. 492; Proctor, Hughes, and Fischman 1988, p. 417).

Unlike the platinum salts, which cause sensitization in exposed workers, platinum metal is of low toxicity. There are no acute toxicity data for platinum metal. In mice and rats receiving platinum metal implants, local-site tumorigenic responses were seen (RTECS 1990). The limit being proposed by OSHA reflects good industrial

hygiene practice and acknowledges that heavy metal dusts are more toxic than particulates not elsewhere classified (for which the PELs are 8-hour TWAs of 10 mg/m³).

OSHA is proposing an 8-hour TWA limit of 1.0 mg/m³ for platinum metal. The Agency believes that this limit is necessary to protect workers in construction, maritime, and agriculture against the adverse health effects potentially associated with workplace exposures to this substance. In addition, promulgation of the proposed PEL will make the limit for platinum consistent across all OSHA-regulated sectors. RESORCINOL

CAS: 108-46-3; Chemical Formula: C₆H₄(OH)₂ H.S. No. 1346

OSHA has no limit for resorcinol in construction, maritime, or agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limits being 'proposed. The ACGIH has an 8-hour TLV*-TWA limit of 10 ppm and a TLV*-STEL of 20 ppm for this substance. OSHA is proposing an 8-hour TWA of 10 ppm and a 15-minute STEL of 20 ppm for resorcinol. These are the limits recently established for this substance in general industry.

Resorcinol occurs in the form of sweet-tasting white crystals that, because of impurities, may turn pink on exposure to air and light or on contact with iron. Resorcinol is used to manufacture formaldehyde-resorcinol resins, cosmetics, styphnic acid, pharmaceuticals, dyes, and adhesives, as a crosslinking agent for neoprene, and as a rubber tackifier (ACGIH 1986, p. 511; Hawley's 1987, p. 1006).

Resorcinol is an irritant of the eyes and mucous membranes on acute exposure; chronic exposure causes systemic poisoning. The oral LD50 in rats is 301 mg/kg, and the dermal LD50 in rabbits is 3360 mg/kg (RTECS 1990). Acutely poisoned animals convulse before death (Gosselin, Smith, and Hodge 1984, p. II-191). Applied to the skin of rabbits, resorcinol caused moderate irritation; instillation into the eyes of rabbits caused pain, conjunctival inflammation, and corneal vascularization (Grant 1986, p. 792; RTECS 1990). Daily 6-hour exposures to a resorcinol concentration of 8 ppm for 2 weeks produced no ill effects in rats, guinea pigs, or rabbits. Acute inhalation exposures to a resorcinol-water aerosol at concentrations as high as 7800 mg/m3 for one hour and 2800 mg/m3 for eight hours caused no toxic effects in laboratory animals (Koppers Company 1974, as cited in ACGIH 1986/Ex. 1-3, p. 511). In skin painting studies in mice,

resorcinol was not carcinogenic (IARC 1977, Vol. 15, p. 171). This substance is not mutagenic in microbial or tissue culture assays (HSDB 1990).

In humans, the cutaneous application of solutions or salves containing from 3 to 25 percent resorcinol may result in local hyperemia, itching, dermatitis. edema, corrosion, and the loss of the superficial layers of the skin. If this damage is severe, the following effects may be seen: enlargement of regional lymph glands, restlessness, methemoglobinemia, cyanosis, convulsions, tachycardia, dyspnes, and death (Clayton and Clayton 1981, p. 2588). An epidemiologic study of rubber workers exposed to a hexamethylenetetramine-resorcinol rubber system revealed no specific symptoms caused by resorcinol; resorcinol concentrations at this plant were less than 0.3 mg/m3. In another study, workers reported no irritation or discomfort when concentrations of resorcinol were maintained at 10 ppm or less and exposure lasted for periods of at least 30 minutes (Clayton and Clayton 1981, p. 2588). A recent study reports that 42 workers in an Italian tire factory developed pigmentary dermatosis, characterized by a rusty red pigmentation of the surfaces of the hand; percutaneous absorption of resorcinol was identified as the cause of the condition, which resolved within 1 week of removal from exposure (Abbate, Polito, Puglisi et al. 1989, in Br. J. Ind. Med. 46(3):212-214).

Based on this evidence in humans and animals, OSHA is proposing a PEL of 10 ppm TWA and a STEL of 20 ppm for resorcinol. OSHA preliminarily concludes that these limits together will protect workers in construction, maritime, and agriculture from the significant risks of irritation and systemic toxicity, which are material impairments of health that are associated with occupational exposure to resorcinol. The Agency believes that the proposed limits are necessary to reduce these risks substantially. In addition, promulgation of the proposed PELs will make OSHA's limits for resorcinol consistent across all OSHAregulated sectors.

ROTENONE
CAS: 83-79-4; Chemical Formula:
C₂₃H₂₂O₆
H.S. No. 2139

In general industry, construction, and maritime, OSHA's permissible exposure limit for rotenone is 5 mg/m³ as an 8-hour TWA. There is no PEL in agriculture. The ACGIH has an 8-hour TLV*-TWA of 5 mg/m³ for this

substance. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 5 mg/ m3 for rotenone in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Rotenone is a white, crystalline, odorless material. This substance is a selective contact herbicide or insecticide and is used in flea powders, fly sprays, and moth-proofing agents (ACGIH 1986, p. 515; Hayes 1982, p. 81). Rotenone is used in dairy barns, milk rooms, and animal shelters and on many vegetables and fruits (Hayes 1982, p. 82). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Rotenone causes irritation of the eyes and skin and central nervous system effects in humans and animals. There is also evidence in animals that rotenone causes liver and kidney damage, developmental abnormalities, and cancer. The lowest reported oral LDsos in rats and mice are 60 mg/kg and 350 mg/kg, respectively (RTECS 1990). Acutely poisoned animals show signs of respiratory stimulation, followed by respiratory depression, incoordination, convulsions, and tremors before death (Hayes 1982, p. 82). Applied to the eyes of rabbits, rotenone causes intense irritation and pus formation (Hayes 1982, p. 82). An oral dose of 1600 mg/kg caused gastrointestinal effects in rabbits, including ulceration, hypermotility, and diarrhea (RTECS 1990). Intravenous administration of rotenone to experimental animals causes vomiting, incoordination, muscle tremors, clonic convulsions, and respiratory failure (Shepard 1949; Shimkin and Anderson 1936, in Gosselin, Smith, and Hodge 1984, p. III-366). Dogs fed 5 mg/kg/day rotenone for 1 month showed fatty changes of the liver and kidneys at autopsy (Hayes 1982, p. 83). Oral doses of 10 mg/kg given to pregnant rats on days 6 to 15 of pregnancy were fatal to 12 of 20 dams and caused a decrease in the number of live fetuses per surviving dam and an increase in the number of resorptions (Khera et al. 1982, in Proctor, Hughes, and Fischman 1988, p. 437) Musculoskeletal abnormalities were seen in the fetuses of rats given 5 mg/kg oral doses of rotenone on days 6 through 15 of pregnancy (RTECS 1990; Proctor, Hughes, and Fischman 1988, p. 437). Intraperitoneally injecting 40 female rats with 1.7 mg/kg of rotenone in sunflower oil for 42 days produced mammary

tumors in 60 percent of the rats within 6 to 11 months of the end of treatment: none of the controls developed tumors after treatment (Gosalvez and Merchant 1973, in Proctor, Hughes, and Pischman 1988, p. 437). There was a slight increase in the incidence of parathyroid gland adenomas among rats given 75 ppm rotenone in their diets for 2 years; female rats given 38 ppm rotenone in the diet for 2 years showed an increased incidence of subcutaneous tissue tumors (Proctor, Hughes, and Fischman 1988, p. 437).

In humans, local effects of rotenone exposure include conjunctivitis, dermatitis, pharyngitis, and rhinitis; oral ingestion causes gastrointestinal irritation, nausea, and vomiting (Klaassen 1986, p. 552; Proctor, Hughes, and Fischman 1988, p. 436). The lowest lethal oral dose in humans is estimated to be 143 mg/kg; at this level, individuals experienced gastrointestinal effects (RTECS 1988). Inhalation of rotenone dust produces respiratory stimulation followed by depression and convulsions (Klaassen, Amdur, and Doull 1986, p. 552).

Based on this evidence in humans and animals, OSHA preliminarily concludes that rotenone causes severe eye and skin irritation and central nervous system effects in exposed individuals. OSHA preliminarily finds that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. OSHA believes that establishing a PEL for rotenone of 5 mg/m3 as an 8hour TWA is necessary to reduce these risks of material health impairment. Promulgation of this limit will also make the PEL for rotenone consistent across all OSHA-regulated sectors. SULFUR HEXAFLUORIDE CAS: 2551-62-4; Chemical Formula: SF6

H.S. No. 2146

OSHA's permissible exposure limit for sulfur hexafluoride in general industry, construction, and maritime is 1000 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH has an 8-hour TLV*-TWA limit of 1000 ppm for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing a PEL of 1000 ppm as an 8hour TWA for sulfur hexafluoride in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Sulfur hexafluoride is a colorless, odorless gas. It is used as a gaseous insulator for electrical equipment and as a tracer gas for ventilation measurements in occupied spaces

(ACGIH 1986, p. 543(87); Braker and Mossman 1980, p. 649).

Exposure to sulfur hexafluoride can cause nervous system effects and asphyxiation in humans and animals. The intravenous LD₅₀ in rabbits is 5790 mg/kg (RTECS 1989). Rats exposed to an atmosphere containing 80 percent (800,000 ppm) sulfur hexafluoride and 20 percent (200,000 ppm) oxygen for 16 to 24 hours showed no observable effects from the exposure (ACGIH 1986, p. 543(87)). Acute exposure to a sulfur hexafluoride concentration of 300 g/m3 produced effects on the nervous system and behavior of rats (Melnikova and Rozova 1981, in HSDB 1986). Under chronic conditions, guinea pigs and rats also showed signs of nervous system effects; changes in the livers and kidneys of these animals were seen at autopsy (Melnikova and Rozova 1981, in HSDB 1986).

Inhaling an 80:20 sulfur hexafluorideoxygen mixture for 5 minutes caused peripheral tingling, excitement, and some alterations in hearing in humans (Glauser and Glauser 1966, in Proctor, Hughes, and Fischman 1988, p. 451). In a recent incident involving two workers exposed to sulfur hexafluoride (and its electrically induced breakdown products), both workers collapsed; the sulfur hexafluoride concentration was estimated to be 1500 ppm (Pilling and Jones 1988). Both men were disoriented and only semi-conscious, and both had headaches. One of these workers developed pulmonary edema within 90 minutes of rescue; signs and symptoms included cyanosis, dyspnea, and bloody sputum (Pilling and Jones 1988).

Based on this evidence in humans and animals, OSHA preliminarily concludes that sulfur hexafluoride causes asphyxia and affects the nervous system in exposed individuals. OSHA preliminarily finds that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these effects. The Agency believes that establishing an 8-hour TWA limit of 1000 ppm for sulfur hexafluoride in agriculture is necessary to reduce substantially the risks of these material health impairments. Promulgation of this limit will also make OSHA's PEL for this substance consistent across all OSHAregulated sectors.

TANTALUM (METAL DUST AND OXIDE)

CAS: 7440-25-7; Chemical Formulas: (Tantalum metal) Ta; (Tantalum oxide) Ta2Os

H.S. No. 1382

OSHA's PEL for tantalum dust and oxide in construction, maritime, and

general industry is 5 mg/m3 as an 8-hour 1,1,2,2-TETRACHLORO-1,2-TWA. There is no limit for these substances in agriculture. NIOSH has no REL for tantalum dust or its oxide but concurs (Ex. 8-47, Table N1) with the limit being proposed. The ACGIH has a TLV*-TWA of 5 mg/m3 and a TLV*-STEL of 10 mg/m³ for these substances. OSHA is proposing an 8-hour TWA PEL of 5 mg/m3 for tantalum metal dust and oxide in agriculture. Promulgation of this PEL will make the limit for these substances consistent across all OSHAregulated sectors.

Tantalum dust is a black powder, and tantalum oxide is a white, microcrystalline powder. These substances are odorless. Tantalum metal is used in chemical equipment, rectifiers, furnace parts, tools, body implants, and electronic equipment. The oxide is used in optical glass and in piezoelectric, maser, and laser applications (ACGIH 1986, p. 544 (88);

Hawley's 1987, p. 1120).

There are no acute toxicity data for the metal; however, the oral LD50 in the rat for tantalum oxide is 8000 mg/kg (RTECS 1990). Intratracheal administration of 100 mg tantalum oxide to guinea pigs produced "soft white circumscribed pigmented dust lesions" in their lungs; no fibrosis was seen (ACGIH 1986/Ex. 1-3, p. 554 (88)). Additionally, this study demonstrated transient bronchitis, interstitial pneumonitis, and hyperemia in these animals after administration of the oxide. Implanted into rats, 3760 mg/kg tantalum metal caused injection-site tumors (RTECS 1990).

In humans, tantalum oxide has been used as a dressing for burns (Olsen 1944/Ex. 1-651), and the use of tantalum gauze in surgical repair produced no long-term adverse effects (Dales and Kyle 1958/Ex. 1-587). No adverse health effects have been associated with industrial exposures to tantalum or tantalum oxide (Cochran, Doull, Mazur,

and DuBois 1950/Ex. 1-586).

Based on this evidence, OSHA is proposing a 5-mg/m3 8-hour TWA PEL for tantalum and tantalum oxide. OSHA preliminarily concludes that this limit will protect workers in agriculture from the significant risk of respiratory effects potentially associated with occupational exposure to these substances. These respiratory effects constitute a material impairment of health, and the Agency believes that the proposed limit is necessary to reduce this risk substantially. In addition, promulgation of the proposed limit will make OSHA's limit for tantalum metal dust and oxide consistent across all OSHA-regulated sectors.

DIFLUOROETHANE CAS: 76-12-0; Chemical Formula: CFCl2CFCl2 H.S. No. 2154

OSHA's limit for 1,1,2,2-tetrachloro-1,2-difluoroethane in general industry. construction, and maritime is 500 ppm as an 8-hour TWA. There is no PEL for this substance in agriculture. The ACGIH TLV*-TWA for this substance is 500 ppm. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing a 500- ppm 8-hour TWA PEL for 1,1,2,2tetrachloro-1,2-difluoroethane in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated

1,1,2,2-tetrachloro-1,2-difluoroethane, also called Freon 12, is a noncombustible, colorless liquid or solid with a faint, ether-like odor (ACGIH 1986, p. 560; HSDB 1989). This substance is used as a refrigerant. It is also used as a solvent, a blowing and foaming agent. and a corrosion inhibitor in the dry cleaning, polymer and plastics, and electrical industries. In addition, it is used in veterinary medicine as a flukicide and antihelminthic (HSDB

1989; ACGIH 1986, p. 560).

In animals, 1,1,2,2-tetrachloro-1,2difluoroethane is a mild irritant of the skin and eyes; at high concentrations, it causes central nervous system depression. The oral LD50 in mice is 800 mg/kg, and the LC50 in rats is 2 parts per hundred (20,000,pph) for 15 minutes (RTECS 1989). Applied to the skin and eyes of guinea pigs, 1,1,2,2-tetrachloro-1,2-difluoroethane caused mild irritation (RTECS 1989). This substance also caused mild irritation in contact with the eyes of rabbits (Proctor, Hughes, and Fischman 1988, p. 460). All rats exposed to 1,1,2,2-tetrachloro-1,2-difluoroethane concentrations of 20,000 to 30,000 ppm for 1 to 2.5 hours died, and the lungs of these animals were severely hemorrhagic at autopsy (Greenberg and Lester 1950, in ACGIH 1986, p. 560). Exposure to 15,000 ppm for 4 hours was fatal to rats; before death, the animals exhibited excitability, incoordination, coma, rapid respiration, tremor, and convulsions, and autopsy showed pulmonary edema and congestion of the lungs and liver (Clayton, Sherman, and Morrison 1966, in ACGIH 1986, p. 560; Proctor, Hughes, and Fischman 1988, pp. 459-460). Rats exposed to 5000 ppm for 18 hours became comatose and died; autopsy revealed pulmonary damage (Greenberg and Lester 1966, in Proctor, Hughes, and Fischman 1988, p. 460). Rats exposed to a concentration of 3000 ppm

developed difficult breathing, mild incoordination, and hyperresponsiveness, but these signs subsided after cessation of exposure (Clayton, Sherman, and Morrison 1966, in Proctor, Hughes, and Fischman 1988. p. 460). Rats given 2 g/kg 1.1,2.2tetrachloro-1,2-difluoroethane daily for 23 to 33 days showed no pathologic changes at autopsy (Greenberg and Lester 1950, in ACGIH 1986, p. 560). Female rats exposed to a concentration of 1000 ppm for 6 hours/day for a total of 31 days had a decreased leucocyte count (Clayton, Sherman, and Morrison 1966, in Proctor, Hughes, and Fischman 1988, p. 460).

Based on effects seen in animals. 1.1,2,2-tetrachloro-1,2-difluoroethane is expected to cause central nervous system depression and pulmonary damage in humans exposed to high concentrations. Early industrial experience with fluorocarbon refrigerants showed that humans exposed to vapor concentrations of approximately 200,000 ppm experienced pulmonary irritation and tremors and became disoriented and comatose; removal from exposure reversed these effects, and there were no sequelae (Gosselin, Smith, and Hodge 1984, p. II-159). Prolonged skin contact with liquid fluorocarbons such as freon 12 causes defatting and may lead to dermatitis

(Parmeggiani 1983, p. 897).

Based on this evidence, OSHA is proposing a PEL of 500 ppm as an 8-hour TWA for 1,1,2,2-tetrachloro-1,2difluoroethane in agriculture. The Agency believes that this PEL is necessary to reduce substantially the significant risk of irritation and central nervous system depression, which OSHA considers material health impairments. Promulgation of the proposed limit will also make OSHA's PEL for 1,1,2,2-tetrachloro-1,2difluoroethane consistent across all OSHA-regulated sectors.

1.1,1,2-TETRACHLORO-2,2-DIFLUOROETHANE CAS: 76-11-9; Chemical Formula: CCl₃CF₂Cl H.S. No. 2153

OSHA's limit for 1,1,1,2-tetrachloro-2.2-difluoroethane in general industry. construction, and maritime is 500 ppm as an 8-hour TWA. There is no PEL for this substance in agriculture. The ACGIH TLV*-TWA is 500 ppm. There is no NIOSH REL; however, NIOSH concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing a PEL of 500 ppm for 1,1,1,2tetrachloro-2,2-difluoroethane in agriculture. Promulgation of this limit

will make the PEL for this substance consistent across all OSHA-regulated sectors.

1,1,1,2-Tetrachloro-2,2-difluoroethane is a noncombustible, colorless solid with a faint, ether-like odor. This substance is used as a refrigerant, a solvent, a blowing and foaming agent, and a corrosion inhibitor. It is also used in the dry cleaning, polymer and plastics, and electrical industries (HSDB 1989, ACGIH 1986, p. 560). Because of their adverse effects on stratospheric ozone, the use of chlorofluorocarbons as aerosol spray propellants was banned in 1979 (HSDB 1989).

In animals, 1,1,1,2-tetrachloro-2,2difluoroethane is a central nervous system depressant at very high concentrations, and repeated exposure to lower levels has caused blood and liver changes. The lowest lethal concentration in rats is 20,000 ppm for 30 minutes (RTECS 1989). Rats exposed to a 10,000-ppm concentration for 90 to 120 minutes showed signs of mild central nervous system depression but no ataxia. Exposure to higher concentrations (20,000 to 30,000 ppm), however, was fatal to rats within 1 to 2.5 hours. Repeated exposure to a 1000-ppm concentration for 18 hours/day for 17 days caused no post-mortem lung, liver, or spleen changes in rats (Greenberg and Carter 1950, in ACCIH 1986, p. 560). However, rats exposed to a 1000-ppm concentration for 31 six-hour exposures showed leukopenia and liver changes at autopsy (Clayton, Sherman, Morrison et al. 1966, in ACGIH 1986, p. 560). Rats given 1,1,1,2-tetrachloro-2,2difluoroethane at an oral dose of 2 mg/ kg/day for 23 to 33 days showed no organ pathology at autopsy.

No information is available on industrial exposure to 1,1,1,2tetrachloro-2,2-difluoroethane. Based on the effects seen in animals, exposure to high concentrations may cause central nervous system depression. In contact with the skin, this substance, like all solvents, is expected to cause defatting and dermatitis.

Based on this evidence, OSHA is proposing a PEL of 500 ppm for 1,1,1,2tetrachloro-2,2-difluoroethane in agriculture. The Agency believes that this PEL is necessary to reduce substantially a significant risk of potential central nervous system depression, which is a material health impairment. Promulgation of the proposed limit would make OSHA's PEL for 1,1,1,2-tetrachloro-2,2-difluoroethane consistent across all OSHA-regulated sectors.

TRIFLUOROBROMOMETHANE CAS: 75-63-8; Chemical Formula: CBrF₃ H.S. No. 2164

OSHA's limit for trifluorobromomethane in general industry, construction, and maritime is 1000 ppm as an 8-hour TWA. There is no PEL for this substance in agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. The ACGIH TLV®-TWA for trifluorobromomethane is 1000 ppm as an 8-hour TWA, and this is the limit being proposed by OSHA for agricultural workplaces. This is the limit recently established for this substance in general industry.

Trifluorobromomethane (also called Freon-13B1® and Freon 1301) is a colorless gas with a slight, ether-like odor (Braker and Mossman 1980, p. 70). This substance is used as a fire extinguishant and foam-blowing agent, a chemical intermediate, an erosion inhibitor in hydraulic fluids, a refrigerant in food processing and storage, and a metal hardener (HSDB

1987).

At very high concentrations, trifluorobromomethane causes cardiac irregularities in humans and animals. The LCso in rats is 416 g/m3 for an unspecified duration (RTECS 1990). Dogs exposed to a 200,000-ppm concentration of trifluorobromomethane for 3 minutes became agitated and developed tremors; when the concentration was increased to between 500,000 and 800,000 ppm, half of the exposed dogs had epileptiform seizures (Van Stee and Back 1969, in Proctor, Hughes, and Fischman 1988, p. 495). Injection of epinephrine caused arrhythmias in all animals exposed to a 400,000-ppm concentration of trifluorobromomethane (Van Stee and Back 1969). After a 5- to 10-µg/m3 dose of epinephrine, dogs experienced ventricular fibrillation and cardiac arrest at 400,000 ppm trifluorobromomethane and monkeys experienced spontaneous defibrillation (Van Stee and Back 1969). No clinical signs of adverse effects were seen in dogs and cats exposed daily to trifluorobromomethane concentrations of 23,000 ppm for 18 weeks, and autopsy revealed no pathological changes in these animals (Comstock et al. 1953, in ACGIH 1986, p. 605).

Humans exposed to very high concentrations of trifluorobromomethane develop cardiac irregularities; volunteers exposed to a concentration of 169,000 ppm developed atrial-ventricular dissociation and premature ventricular beats (Hine et al. 1968, in ACGIH 1986, p. 605). Volunteers exposed for 3 minutes to a concentration of trifluorobromomethane of between

40,000 and 70,000 ppm showed increased reaction times (Call 1973, in ACGIH 1986, p. 605). In contact with the skin or eyes, liquid pressurized trifluorobromomethane causes frostbite (Clayton and Clayton 1981, p. 3102).

Based on this evidence in humans and animals, OSHA preliminarily concludes that, in the absence of a PEL, workers in agriculture are at significant risk of experiencing cardiac irregularities. Accordingly, OSHA is proposing an 8-hour TWA PEL of 1000 ppm for trifluorobromomethane in agriculture. In addition, promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

TRIMETHYL PHOSPHITE CAS: 121-45-9; Chemical Formula: (CH3O)3P H.S. No. 1410

OSHA has no limit for trimethyl phosphite in construction, maritime, and agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. The ACGIH TLV® for this substance is 2 ppm as an 8-hour TWA. OSHA is proposing an 8-hour TWA PEL of 2 ppm for trimethyl phosphite; this is the limit recently established for this substance in general industry.

Trimethyl phosphite is a colorless liquid with a pungent odor. This substance is used as an intermediate in the manufacture of pesticides, fire retardants, and organic phosphorus additives (ACGIH 1986, p. 609; HSDB 1989).

Trimethyl phosphite's toxic effects include eye, mucous membrane, skin, and pulmonary irritation. The oral LD50 in rats is 1600 mg/kg, and the lowest lethal dermal concentration in rabbits is 2200 mg/kg (RTECS 1990). Applied to the skin of rabbits, trimethyl phosphite caused severe irritation; instilled into the eyes of rabbits, it produced only mild irritation (RTECS 1990). Rats exposed to concentrations ranging from 100 to 600 ppm showed dose-dependent effects, including labored breathing, lacrimation, salivation, reduced activity, cold feet, and corneal opacities; at the highest concentration, mature and irreversible cataracts were formed (EPA 1982, in Dialog NIOSHTIC off-prints). Rats inhaling 500 ppm for 8 weeks showed premalignant changes in the lungs at autopsy (EPA 1982). In a subchronic inhalation study of rats, Levin and Gabriel (1973/Ex. 1-746) found that exposure to trimethyl phosphite at concentrations of 500 ± 75 ppm for 7.5 hours/day, 5 days/week for 8 weeks caused an adverse effect on body

weight; necropsy revealed evidence of severe pulmonary and cutaneous pathology. At doses of 164 mg/kg during gestation days 8 to 15, trimethyl phosphite caused gross abnormalities in the offspring of treated rats (Mehlman, Craig, and Gallo 1984, in Toxicol. Appl. Pharmacol. 72(1):119–123).

In humans, exposure to trimethyl phosphite causes eye, skin, and upper respiratory tract irritation (Levin and Gabriel 1973/Ex. 1–746). In a group of 179 workers exposed to average concentrations of trimethyl phosphite of between 0.3 and 4 ppm, no ocular changes were observed (Mobil Chemical Company 1980, as cited in ACGIH 1986/Ex. 1–3, p. 609).

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 2 ppm for trimethyl phosphite. The Agency preliminarily concludes that this limit will protect workers in construction, maritime, and agriculture from the significant risk of eye damage, skin irritation, and upper respiratory tract irritation, all material impairments of health that are potentially associated with exposures to this substance at levels permitted in the absence of a limit. In addition, promulgation of the proposed PEL will make the limit for trimethyl phosphite consistent across all OSHA-regulated sectors.

TRIPHENYL AMINE
CAS: 603-34-9; Chemical Formula:
(C₆H₆)₅N
H.S. No. 1415

OSHA has no exposure limit for triphenyl amine in construction, maritime, or agriculture. NIOSH has no REL but concurs (Ex. 8–47, Table N1) with the limit being proposed. The ACGIH has a 5-mg/m³ TLV*-TWA limit for this substance. OSHA is proposing an 8-hour TWA PEL of 5 mg/m³ for triphenyl amine; this is the limit recently established for this substance in general industry.

Triphenyl amine is a colorless solid that takes the form of monoclinic prisms. It is used as a primary photoconductor to coat film bases (ACGIH 1986, p. 612; HSDB 1989).

Animal studies conducted by the Eastman Kodak Company (Roudabush 1973, as cited in ACGIH 1986/Ex. 1–3, p. 612) showed an oral LD₅₀ in rats of 3200 to 6400 mg/kg and an oral LD₅₀ in mice of 1600 to 3200 mg/kg. The LD₅₀ by intraperitoneal administration for both rodent species exceeded 6400 mg/kg. Skin and eye sensitivity tests in both rabbits and guinea pigs were essentially negative, except that application to the skin of 5 to 20 ml/kg occlusively for four hours produced slight dermal erythema

(Roudabush 1973, as cited in ACGIH 1986/Ex. 1-3, p. 612).

Based on this animal evidence, OSHA is proposing a 5-mg/m3 TWA limit for triphenyl amine. OSHA preliminarily concludes that this limit is necessary to protect workers in construction, maritime, and agriculture from the significant risk of skin irritation, a material health impairment that is potentially associated with occupational exposure to this substance at levels permitted by the absence of an OSHA PEL. In addition, promulgation of the proposed PEL will make OSHA's limit for triphenyl amine consistent across all OSHA-regulated sectors. TRIPHENYL PHOSPHATE

CAS: 115-86-6; Chemical Formula (C₆H₅O)₃PO₄ H.S. No. 2165

In general industry, construction, and maritime, OSHA has an 8-hour TWA PEL of 3 mg/m³ for triphenyl phosphate. The Agency has no PEL for this substance in agriculture. The ACGIH has a TLV*-TWA of 3 mg/m³ for this substance; NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL in agriculture of 3 mg/m³ for triphenyl phosphate. This is the limit recently established for this substance in general industry.

The principal use for triphenyl phosphate is as a noncombustible plasticizer for cellulosics; however, this substance is also used in impregnating roofing paper and upholstery, as a plasticizer in lacquers and varnishes, and in rendering acetyl cellulose, nitrocellulose, and airplane "dope" stable and fireproof (HSDB 1985). Triphenyl phosphate is a colorless to white crystalline solid with a phenollike odor. It may also take the form of white platelets (HSDB 1985).

Triphenyl phosphate causes cholinesterase inhibition in both animals and humans; in laboratory animals, this substance also causes neurotoxic effects. The oral LDso in rats is 3500 mg/ kg, and the lowest lethal dose by subcutaneous injection in the monkey is 500 mg/kg (RTECS 1989; Clayton and Clayton 1981, p. 2367). Acutely poisoned rats developed tremors and lost motor coordination before death (RTECS 1989). Mice given triphenyl phosphate orally or intraperitoneally at a dose of 0.2 g/kg showed a 50 percent decrease in plasma cholinesterase levels, and exposure to triphenyl phosphate at a concentration of 757 mg/m3 for 2 hours produced a slight but statistically significant decrease in whole blood cholinesterase activity (Sutton, Terhaar, Miller,

Scherberger, Riley, Roudabush, and Passet 1960). Recent work suggests that triphenyl phosphate may not have been responsible for the delayed neurotoxicity seen in earlier studies but that an impurity in the triphenyl phosphate may have been responsible (Wills et al. 1979, cited in HSDB 1985). Applied to the skin of rats and mice, triphenyl phosphate caused no irritation and no inhibition of cholinesterase activity (Antonyuk 1974; Sutton et al. 1960). Slightly depressed growth rates and increased liver weights were seen in rats fed 0.5 percent triphenyl phosphate for 35 days; these effects were not observed in rats fed 0.1 percent triphenyl phosphate for this period (Sutton et al. 1960).

No adverse clinical effects were observed in 16 workers who were exposed for 8 to 10 years to the vapor, mist, and dust forms of triphenyl phosphate at an average concentration of 3.5 mg/m3 (with brief exposures to peaks of 40 mg/m3). However, a slight but statistically significant reduction in red blood cell cholinesterase activity was noted in these workers (Sutton et al. 1960). A study of workers manufacturing aryl phosphates (including triphenyl and tricresyl phosphate) failed to show a correlation between airborne concentration (0.2 to 3.4 mg/m3 aryl phosphate) or duration of exposure to these substances and the gastrointestinal or neuromuscular symptoms reported by these workers (Tabershaw, Kleinfeld, and Feiner 1957a, b). One apparent case of skin sensitization caused by exposure to triphenyl phosphate has been recorded (Clayton and Clayton 1981, p. 2381).

Based on this evidence, OSHA preliminarily concludes that, in the absence of a permissible exposure limit, workers in agriculture are at significant risk of experiencing the cholinesterase inhibition associated with exposure to triphenyl phosphate. The Agency believes that establishing an 8-hour TWA PEL of 3.0 mg/m³ will substantially reduce this risk. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

URANIUM (INSOLUBLE COMPOUNDS) CAS: 7440-61-1; Chemical Formula: U H.S. No. 1418

OSHA's PEL for insoluble uranium compounds in the construction and maritime industries is 0.25 mg/m³ as an 8-hour TWA. There is no limit for these substances in agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limits being proposed. The

ACGIH has a TLV*-TWA of 0.2 mg/m3 and a TLV®-STEL of 0.6 mg/m3 for these substances. OSHA is proposing an 8-hour TWA of 0.2 mg/m3 and a STEL of 0.6 mg/m3 for the insoluble uranium compounds; these are the limits recently established for these compounds in general industry.

Uranium is a silver-white radioactive metal that has no odor. Uranium is used in nuclear fuels and weapons, in research, as a catalyst in gas manufacture, and as a source of radium salts and fissionable isotopes (ACGIH 1986, p. 617; HSDB 1986). The proposed PEL would apply to metallic uranium and such compounds as triuranium octaoxide, uranium dioxide, uranium hydride, uranium tetrafluoride, and uranium trioxide.

Exposure to uranium and the insoluble uranium compounds may produce both chemical poisoning and radiation injury to the kidneys and lungs of exposed animals. The insoluble uranium compounds are less toxic chemically than the soluble compounds, but uranium and all uranium compounds have the potential to cause radiation damage. Acute inhalation of 20 mg/m3 concentrations of uranium tetrafluoride, uranium dioxide, or high-grade uranium ore is occasionally fatal to some laboratory animals; exposure to 2.5 mg/ m3 concentrations of these substances, however, caused no fatalities and evidence of mild kidney damage only in a few animals (Clayton and Clayton 1981, p. 2002).

Chronic exposure to uranium or its compounds causes radiation injury in animals. Dogs and monkeys exposed to 5 mg/m3 uranium dioxide 6 hours/day, 5 days/week for up to 5 years developed fibrotic changes (suggestive of radiation injury) in their tracheobronchial lymph nodes (both species) and, in monkeys, in the lungs (Clayton and Clayton 1981, p. 2002). Dogs tolerated exposure to a 10 mg/m3 concentration of uranium dioxide for 1 year and to a 10 g/kg/day dietary dose of the same substance for 1 year. Rats injected with metallic uranium in the femoral bone marrow and chest wall developed site-of-contact tumors (sarcomas); the effects of chemical injury and radiation damage could not be distinguished in these lesions (Clayton and Clayton 1981, p.

2003).

In humans, over-exposure to uranium dust or an insoluble uranium compound causes respiratory irritation, difficult breathing, and coughing. A recent review of uranium's nephrotoxicity suggests that it causes damage to the human kidney at renal uranium concentrations substantially below those previously believed to cause harm

(Leggett 1989). Uranium workers are at increased risk of death due to pulmonary insufficiency and respiratory, lymphatic, and hematopoietic cancers; these effects are believed to be caused by the decay products of uranium rather than by the uranium itself (Parmeggiani 1983, p. 2238). A study of the risk of respiratory deaths among uranium miners in the United States showed the following dose response: Miners exposed for 5 to 9.9 years had a twofold increase in risk; miners exposed for 10 to 24.9 years increase their risk by 3.6; and those exposed for longer than 24.9 years increased their risk by 3.75. Smoking was shown both to increase the risk of death from respiratory disease and to shorten the neoplastic latency period (Clayton and Clayton

1981, pp. 2010-2011).

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 0.2 $\rm mg/m^3$ and a STEL of 0.6 $\rm mg/m^3$ in construction, maritime, and agriculture for uranium and the insoluble compounds of uranium. The Agency preliminarily concludes that these limits are required to protect workers in these sectors from the significant risks of kidney or blood disorders and radiological damage potentially associated with both long-term and excursion exposures to these compounds. The Agency considers these adverse effects to be material impairments of health and believes that these limits will substantially reduce these risks. In addition, promulgation of the proposed limits will make the PELs for the insoluble uranium compounds consistent across all OSHA-regulated sectors.

Preliminary Conclusions for this Group of Substances

For the group of substances shown in Table C9-1, OSHA preliminarily concludes that occupational exposure causes a broad range of adverse health consequences in exposed workers in construction, maritime, and agriculture; these effects include, among others, central nervous system depression, respiratory irritation, liver and kidney damage, cardiac sensitization, and hepatocellular cancer; OSHA considers all of these effects material impairments of health. The Agency believes, based on a thorough review of the available toxicological evidence, that the proposed limits are necessary to reduce the significant risk of material health impairment associated with occupational exposures to these systemic toxins. Promulgation of these proposed limits will also make OSHA's PELs for these substances consistent across all OSHA-regulated sectors,

including general industry, construction, maritime, and agriculture.

10. Substances for Which Proposed Limits Are Based on Avoidance of Physical Irritation and Other Effects

Introduction

In construction, maritime, and agriculture, OSHA is proposing to establish permissible exposure limits for a large group of substances that cause a variety of irritant and other adverse effects. These substances are called "particulates not otherwise regulated" because they are dusts and particulates* that have not been classified in any of the target organ categories addressed in this preamble.

OSHA previously had no substancespecific limits for these Individual physical irritants in construction, maritime, or agriculture; the Agency's current generic limit for particulates is 15 mg/m3 as total particulate and 5 mg/ m³ as respirable particulate (see Table Z-3 of 29 CFR 1910.1000). OSHA is listing these substances individually in the proposed rule and is proposing either the 15 mg/m³ total particulate limit and the respirable fraction limit of 5 mg/m3 or a 10 mg/m3 8-hour TWA limit (total particulate) and a 5 mg/m3

(respirable fraction limit).

The health effects information available for these substances has led OSHA to separate them into two groups and to propose different limits for the substances in each group. For one group, which contains substances for which few data are available and which are believed to be of relatively low toxicity, OSHA is retaining the Agency's 8-hour TWA generic particulate limit of 15 mg/ m3 (measured as total particulate) in construction and maritime; in addition, where the Agency previously had a 5 mg/m3 8-hour TWA respirable fraction limit for a substance in this group, this limit is being retained in construction and maritime. For all of the substances in this first group, OSHA is proposing 8hour TWA PELs of 15 mg/m3 (total particulate) and 5 mg/m3 (respirable fraction) in agriculture; OSHA does not currently regulate particulates in agriculture.

For the second group of particulates not otherwise regulated, additional toxicological information is available that indicates that exposure leads both to physical irritation and to other health effects. For the substances in this group, OSHA is proposing 8-hour TWA PELs of

^{*} Because the term particulate applies to dusts. aerosols, and mists, OSHA uses this term generically in this section to apply to all of these states of matter.

10 mg/m3 (measured as total particulate) and, where applicable, 5 mg/m3 (measured as the respirable fraction) for workplaces in all three of the sectors of interest in this rulemaking. physical irritations have proposed PELs Table C10-1 shows all of the particulates included in this section; those whose principal health effects are

of 15 mg/m3 (total particulate and 5 mg/ m3 (respirable fraction).

¹ OSHA is proposing to retain the Agency's generic 5-mg/m² respirable-fraction PEL for particulates where it currently applies in construction and maritime.

OSHA's TWA PELs are for 8-hour exposures.

The ACGIH TLV²-TWA is for an 8-hour exposure.

For the second group of substances in this category, however, OSHA has reviewed the available toxicological literature and has preliminarily determined that the current generic total particulate limit of 15 mg/m3 is not sufficiently protective. For these substances, the adverse health effects associated with exposure include, in addition to physical irritation, chronic pulmonary disease, cancer, and mutagenic, reproductive, and teratogenic effects. In the past, many of these substances were designated as

"nuisance" dusts or particulates; however, recent toxicologic studies or evidence in humans has increasingly shown that exposure leads to serious health effects. Thus, as applied to these substances, the term nuisance dust is a misnomer, because the hazards these substances pose in the workplace are real, well-documented, and potentially serious. NIOSH shares OSHA's concern about this trend in the toxicology of particulates and has already either designated several of these substances. which were formerly considered "inert." as potential occupational carcinogens or labeled them as causing other targetorgan effects. Examples of substances in this category that the recent toxicological literature has suggested may cause more serious effects are: benomyl (reproductive effects); kaolin (pulmonary fibrosis); methoxychlor (cancer); picloram (liver and kidney damage); synthetic graphite (pneumoconiosis); and titanium dioxide (cancer).

In addition to these diseases, toxicologists have recently expressed concern over the identification of a condition known as pulmonary alveolar proteinosis. This condition, which is apparently caused by the physical effects of particulate exposure, can be fatal if not properly diagnosed, although treatment with lung lavage is sometimes effective (NIOSH-ILO 1988). Pulmonary alveolar proteinosis has occurred in workers exposed to several different particulates, including the so-called inert dusts. The onset of this condition may not occur until months after first exposure to the dust.

For the group of physical irritants identified by OSHA as having other adverse health effects, the proposed rule would establish an 8-hour TWA total particulate limit of 10 mg/m3 and a respirable fraction limit of 5 mg/m3 in construction, maritime, and agriculture. The 10 mg/m3 limit is consistent with the limits established for these substances in the recent general industry rulemaking. That is, the limits being proposed today are those recently established for these substances in general industry. Promulgation of these limits will thus make OSHA's PELs for them consistent across all regulated

Description of the Health Effects

The adverse exposure effects caused by the substances in this group for which the Agency's current 15-mg/m3 limit is being retained in construction and maritime and proposed in agriculture include: interference with vision; deposition of these substances in the eyes, ears, nasal passages, and upper respiratory tract; and skin and corneal irritation. For the group of substances for which a limit of 10 mg/ m3 is being proposed in construction, maritime, and agriculture, the additional adverse exposure effects include pulmonary alveolar proteinosis, reproductive effects, irreversible pulmonary effects, liver and kidney effects, systemic poisoning, and cancer. As discussed above, these latter effects are increasingly being linked to exposure to these substances, many of which were formerly considered biologically inert.

Thus, workers exposed to excessive airborne concentrations of any of these physical irritants may have difficulty seeing, may cough uncontrollably, may develop conjunctivitis or dermatitis, or may develop disabling or even lifethreatening disease. In addition to these primary effects, workers distracted by physical-irritant effects may be more likely than nonexposed workers to have accidents and thus to endanger both themselves and others. (These adverse

health effects also clearly have substantial productivity impacts.)

In the prior rulemaking, many commenters opposed any reduction in the PELs for these substances on the grounds that the evidence that exposure leads to material impairment of health was inadequate (Exs. 3–1123, 3–726, 3–755, 3–887, 3–898, 3–939, 3–1012, 3–1016, and 8–22). In that rulemaking, OSHA was not persuaded by these arguments and cited the International Labour Organization to the effect that:

[T]he biological effects of these inert dusts are of a long-term nature and are neither fibrogenic nor carcinogenic, toxic or allergenic. In excessive quantities they will overcharge the protective and scavenging mechanisms, thereby leading to respiratory disease. The extent to which any type of dust represents a health risk thus depends on exposure, which includes the nature of the dust, its concentration and the duration of exposure, as well as upon individual factors such as the general constitution and state of health of the person concerned, including the functional state of the upper respiratory tract. the lung function and its structure, the general immunological status and specific immunological reactivity, and the biochemical reactivity. All these factors will play a part in the onset of disease (Parmeggiani 1983).

OSHA also noted in the earlier rulemaking that a particulate standard of 10 mg/m³ or less (measured as total particulate) is the official standard in a great many countries, including Finland, Denmark, Norway, Sweden, the United Kingdom, Japan, Poland, Czechoslovakia, and the Republic of China (Cook 1987/Ex. 1–187, pp. 234–241).

In addition, OSHA notes with concern the trend in the toxicology of these substances, which is to find increasingly that substances formerly believed to be inert are in fact associated with serious and sometimes life-threatening effects. When exposures to the substances shown in Table C10-1 are kept under good industrial hygiene control in the workplace, as represented by the proposed PELs, OSHA believes that exposures are not likely to result in significant organic disease or irreversible toxic effects among workers exposed to them in construction, maritime, and agriculture.

The following discussions describe OSHA's preliminary findings for this group of physical irritants. In all cases, the limits being proposed for construction, maritime, and agriculture are those that were recently established for these substances in general industry.

ALPHA-ALUMINA CAS: 1344-28-1; Chemical Formula:

Al2O3

H.S. No. 1014

OSHA has no specific limit for alphaalumina in the agriculture, construction, or maritime industries, although OSHA's generic total particulate limit of 15 mg/ m3 (5 mg/m3 for the respirable fraction) applies to this substance in construction and maritime. The ACGIH has an 8-hour TWA of 10 mg/m3, measured as total dust, for alpha-alumina. NIOSH has no REL for alpha-alumina. OSHA is proposing an 8-hour TWA of 10 mg/m3 (total particulate) for this substance in the construction, maritime, and agriculture industries. The 5-mg/m3 respirable-fraction limit that applies to alpha-alumina is being retained.

Alpha-alumina, also called aluminum oxide, is a white powder that is widely used as an abrasive grinding material. Alpha-alumina is also used in the production of aluminum, in refractories, ceramics, electrical insulation, paper, spark plugs, crucibles, and laboratory wares, in chromatographic analysis, and in fluxes, artificial gems, and light bulbs (Hawley's 1987, p. 48).

A study by Miller and Sayers (1941/Ex. 1-595) determined that alumina particles with diameters of less than 40 microns produced no reaction in laboratory animals. The results of a study by Stacy, King, Harrison et al. (1959/Ex. 1-761) confirmed the findings of Miller and Sayers; these authors found a-alumina to be nearly inert when injected into the lungs of rats (Stacy, King, Harrison et al. 1959/Ex. 1-761). Inhalation of fine aluminum powders at unspecified levels did not cause fibrosis in rats, guinea pigs, or hamsters (Gross, Harley, and deTreville 1973/Ex. 1-696).

In 1923, shortly after a-alumina replaced sandstone as the industrial abrasive of choice, Macklin and Middleton (1923, as cited in ACGIH 1986/Ex. 1-3, p. 21) reported that workers exposed to aluminum oxide dust using the new, synthetic abrasive had much less pulmonary disease than had workers using sandstone abrasives. Other studies (Sutherland, Meiklejohn, and Price 1937/Ex. 1-674; Meiklejohn and Posner 1957/Ex. 1-1060; Meiklejohn and Jones 1948/Ex. 1-964) reported that workers exposed to aluminum exide dust in the chinaware industry and in aluminum production showed no evidence of pneumoconiosis. However, some early studies (Clark and Simmons 1925/Ex. 1-725; Clark 1929/Ex. 1-1048) reported that workers engaged in aluminum oxide production and exposed to dust levels generally between 50 and 100 mppcf showed X ray evidence of pulmonary fibrosis; these workers are likely also to have been exposed to silica. Workers

exposed during World War II to bauxite fumes containing both alumina and silica developed pulmonary fibrosis and emphysema; the authors believe that silica fume was involved in the development of these diseases (Shaver and Riddell 1947/Ex. 1–666). NIOSH (Ex. 8–47, Table N4) reports that two studies in animals (Stacy, King, Harrison et al. 1959/Ex. 1–761; Stanton, Laynard, Tegeris et al. 1981) have found that exposure to alpha-alumina is associated with the development of respiratory effects.

OSHA is proposing 8-hour TWA limits of 10 mg/m3 total particulate and 5 mg/ m3 respirable particulate for alphaalumina in construction, maritime, and agriculture; these limits are being proposed for all physical irritants having identified health effects. The Agency preliminarily concludes that these limits will protect workers in these sectors from the significant risk potentially associated with exposures to alphaalumina dust in the workplace. OSHA believes that skin, eye, and upper respiratory tract irritation and other possible respiratory effects constitute material health impairments, and that the proposed PELs are necessary to substantially reduce these risks. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

ALUMINUM METAL DUST CAS: 7429–90–5; Chemical Formula: Al H.S. No. 1016

OSHA has no specific permissible exposure limit for aluminum metal dust in the agriculture, construction, or maritime industries, although the Agency's generic 15 mg/m³ TWA limit for total particulate applies. The ACGIH has an 8-hour TLV*-TWA limit of 10 mg/m³ as total dust for this substance. NIOSH has no REL for aluminum metal dust. OSHA is proposing a PEL of 15 mg/m³ (total particulate) and 5 mg/m³ (respirable fraction) for aluminum metal dust in the construction, maritime, and agriculture industries. These are the limits recently established in general industry.

In its elemental form, aluminum is a white, malleable, ductile metal. Aluminum is used in building and construction, in the electrical industry, and in auto parts, photoengraving plates, and toothpaste; it also finds use as a powder in paints, as foil in packaging, in decorative stamping, and as flakes for the insulation of liquid fuels (Hawley's 1987, p. 44; Merck 1983, p. 48).

Aluminum metal dust has been shown to present a minimal health hazard,

according to results from the McIntyre Foundation's 27-year study of aluminum oxide dust (discussed in Stokinger 1981a, pp. 1500-1503). No deleterious lung or systemic effects were observed as a result of exposure to aluminum metal dust having a particle size of 1.2 µm at calculated concentrations equivalent to 2 mg/m3 over an 8-hour workshift. Even much higher concentrations (not further specified) over 10- or 20-minute periods produced no adverse effects (ACGIH 1986/Ex. 1-3, p. 22). A comment submitted to the docket in the earlier rulemaking by the Reynolds Aluminum Company endorses OSHA's classification of aluminum metal dust under the general dust and particulate heading (Ex. 3-135).

OSHA has preliminarily concluded that aluminum metal dusts are appropriately controlled by retaining the Agency's PELs of 15 mg/m3 TWA (total particulate) and 5 mg/m3 (respirable fraction) in the construction and maritime industries and by proposing to extend these limits to agriculture. OSHA has preliminarily determined that these limits will provide protection against the significant risk of physical irritation posed by exposure to this substance. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

AMMONIUM SULFAMATE
CAS: 7773-06-0; Chemical Formula:
NH4SO₃NH₂
H.S. No. 1024

In the construction and maritime industries, OSHA currently regulates ammonium sulfamate under its generic total particulate limit of 15 mg/m3. There is no PEL in agriculture. The ACGIH has established a TLV* of 10 mg/m3 for this substance as an 8-hour TWA. There is no NIOSH REL for ammonium sulfamate. A limit of 10 mg/ m3 (and 5 mg/m3 for the respirable fraction) is the limit being proposed by the Agency for construction, maritime, and agricultural operations. NIOSH (Ex. 8-47, Table N4) concurred with this limit when the Agency recently established it in general industry.

Ammonium sulfamate is a combustible, hygroscopic, white, crystalline substance. It is used to manufacture contact and translocated herbicides, such as the weed killer Ammate. Ammonium sulfamate is also used to make fire-retardant materials, to generate nitrous oxide gas, and in electroplating (ACGIH 1986, p. 28). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under

the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Lehman (1951/Ex. 1-790) identified oral LD50s of 3900 and 5700 mg/kg in rats and mice, respectively. He also reported that no effects were noted in rats administered 10,000 ppm ammonium sulfamate in the diet for 105 days. The intraperitoneal injection of 0.8 g/kg of ammonium sulfamate caused stimulation of respiration, followed by prostration, in rats. Six of 10 rats so exposed died (Ambrose 1943). The hazards associated with exposure to ammonium sulfamate include eve and nose irritation, interference with vision, and the danger of accidents caused by the distraction and avoidance reactions typical of workers overexposed to dusts in the workplace.

In construction and maritime, OSHA is proposing a PEL of 10 mg/m3 TWA, total particulate, and is retaining the 5mg/m3 TWA PEL for respirable particulate for ammonium sulfamate; the Agency is also proposing to extend these limits to agriculture. OSHA preliminarily concludes that these limits will protect workers in the construction. maritime, and agriculture industries against the significant risk of material health impairment in the form of physical and other irritation that is associated with exposure to this substance. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

BARIUM SULFATE CAS: 7727-43-7; Chemical Formula:-BaSO₄ H.S. No. 1031

OSHA has no specific limit for barium sulfate in the agriculture, construction, and maritime industries, although OSHA's generic 15-mg/m3 total particulate limit applies in construction and maritime. The ACGIH has a TLV*-TWA of 10 mg/m3, total dust, for this substance. There is no NIOSH REL for barium sulfate. The Agency is proposing 10 mg/m3 as an 8-hour TWA PEL for barium sulfate (total particulate) in construction, maritime, and agriculture. OSHA is retaining the 5-mg/m3 PEL for the respirable fraction in construction and maritime and is proposing to extend this limit to agriculture. These are the limits recently established in general industry for barium sulfate.

Barium sulfate is a white or yellowish, odorless, tasteless powder. It is used as an opaque medium in X-ray examinations, for weighting mud in oildrilling, in paper coatings, paints, rubber, plastics, and lithograph inks, in battery plate expanders, and as a filler

and delustrant for textiles (Hawley's 1987, p. 121).

Einbrodt, Wobker, and Klippel (1972/ Ex. 1-1020) exposed rats to a concentration of 40 mg/m3 for two months and concluded that barium sulfate is not toxic. As an inert dust of the noncollagenous type, however, barium sulfate has the potential to cause pneumoconiosis through tissue reactions to accumulated dust in the lung (Anonymous, British Medical Journal 1972). Barium sulfate has not been known to cause adverse effects in industrial workers exposed over periods of several years (Doig 1976/Ex. 1-551).

In construction and maritime, OSHA is proposing an 8-hour TWA PEL for barium sulfate of 10 mg/m3 (total particulate) and is retaining the 5-mg/m3 8-hour TWA (respirable particulate). The Agency also is proposing to extend both limits to agriculture. OSHA preliminarily concludes that these limits will protect workers in the construction, maritime, and agriculture industries against the significant risks of eye, nose, and upper-respiratory-tract irritation and, perhaps, of pneumoconiosis that are potentially associated with exposure to barium sulfate. The Agency believes these adverse health effects to be material impairments of health and preliminarily finds that the proposed limits are necessary to substantially reduce these risks. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors. BENOMYL

CAS: 17804-35-2; Chemical Formula: C14H18N4O3 H.S. No. 1032

OSHA has no specific permissible exposure limit for benomyl in the agriculture, construction, or maritime industries. OSHA currently covers benomyl in construction and maritime under the generic total particulate limit of 15 mg/m3. The ACGIH has established a total dust TLV®-TWA of 10 mg/m3 for benomyl. NIOSH has no REL for this substance. OSHA is proposing a PEL of 10 mg/m3 as total particulate for benomyl in the construction and maritime industries, retaining the 5-mg/m3 respirable fraction limit in these sectors, and proposing to extend both limits to agriculture. These are the limits recently established for this substance in general industry.

Benomyl is a white crystalline solid; exposures to this substance occur in its particulate form. Benomyl is used as an ascaricide and a post-harvest fungicide for peaches, apples, etc. It is also used as an oxidizer in sewage treatment

(ACGIH 1986, p. 49; Hawley's 1987, p. 127). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Studies of rats and rabbits indicate that the oral and skin absorption LDsos are greater than 10,000 mg/kg, and studies of guinea pigs show a very low risk of skin irritation. Application to the shaved intact skin (as aqueous suspensions containing 5, 12.5, and 25 percent benomyl) of ten male guinea pigs resulted in slight irritation; one of ten guinea pigs had mild erythema two days after application of the high concentration (E.I. du Pont de Nemours and Co., Inc. 1974, as cited in ACGIH 1986/Ex. 1-3, p. 49). In another study, instillation of 10 mg of dry 50-percent powder or of 0.1 ml of a 10-percent suspension in mineral oil caused only temporary mild conjunctival irritation (E.I. du Pont de Nemours and Co., Inc., unpublished data, as cited in ACGIH 1986/Ex. 1-3, p. 49). NIOSH notes that benomyl exposure may cause adverse reproductive effects (Ex. 8-47, p. 12). Mice given an oral dose of 500 mg/kg on the 13th day of pregnancy had offspring with developmental abnormalities of the central nervous and musculoskeletal systems. Rats given oral doses of 158 mg/kg benomyl on days 7 through 16 of pregnancy also had offspring with musculoskeletal abnormalities. Other reproductive effects from exposure to benomyl in mice and rats include adverse effects on spermatogenesis (RTECS 1991).

In humans, skin exposures to a 0.1 percent solution of benomyl caused mild irritation (RTECS 1991). Contact dermatitis occurred among a group of Japanese women who worked in warm moist greenhouses where benomyl was sprayed; this effect occurred after a second spraying of benomyl (Hayes

1982, p. 612).

OSHA is proposing 8-hour TWA PELs in construction, maritime, and agriculture of 10 mg/m3 (total particulate), retaining the 5-mg/m3 respirable particulate limit in construction and maritime, and proposing to extend the respirable fraction limit to agriculture. The Agency preliminarily concludes that these limits will protect workers in the construction, maritime, and agriculture industries from the significant risks of benomyl's effects, which include irritation, erythema, and possible reproductive effects. OSHA believes that these health effects constitute material impairments of health and that the proposed PELs are necessary to reduce these risks. In addition, promulgation of these limits

will make OSHA's PELs for this substance consistent across all regulated sectors. BISMUTH TELLURIDE (UNDOPED) CAS: 1304-82-1; Chemical Formula:

H.S. No. 1035

OSHA has no specific limit for undoped bismuth telluride in the construction, maritime, or agriculture industry, although OSHA's generic total particulate limit of 15 mg/m3 currently applies in construction and maritime. The ACGIH has a total dust TLV®-TWA of 10 mg/m3 for the undoped form of this substance. NIOSH has no REL for undoped bismuth telluride. OSHA is proposing to retain the 15 mg/m3 (total particulate) and 5 mg/m3 (respirable particulate) 8-hour TWA PELs for this substance in construction and maritime and is proposing to extend these limits to agriculture. These are the limits recently established in general industry.

Bismuth telluride appears as gray, hexagonal platelets; it is also available as ingots or single crystals. It is used for semi-conductors and in thermoelectric cooling and power generation applications (ACGIH 1986, p. 59).

An 11-month inhalation study of dogs, rabbits, and rats exposed to pure undoped bismuth telluride dust at 15 mg/m3 showed the pulmonary responses typical of exposures to inert dusts (Wagner, Madden, Zimber, and Stokinger 1974).

OSHA is retaining its permissible exposure limits of 15 mg/m3 TWA, as total particulate, and 5 mg/m3, as the respirable fraction, for pure undoped bismuth telluride in the construction and maritime industries and is proposing to extend these limits to agriculture. The Agency preliminarily concludes that these limits will protect workers in these sectors from the significant risks associated with workplace exposures to bismuth telluride. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors. BORON OXIDE

CAS: 1303-86-2; Chemical Formula: B₂O₃

H.S. No. 1039

In construction and maritime, OSHA currently regulates boron oxide under its generic total particulate limit of 15 mg/ m3 (5 mg/m3 for the respirable fraction). There is no PEL in agriculture. The ACGIH recommends a total dust TLV*-TWA of 10 mg/m3. OSHA is proposing a total particulate PEL for boron oxide of 10 mg/m8 in construction and maritime, retaining the 5-mg/m3 PEL for the respirable fraction in these two sectors,

and proposing to extend both limits to agriculture. NIOSH (Ex. 8-47, Table N4) concurred with these limits when the Agency recently established them for boron oxide in general industry.

Boron oxide occurs as either a white powder or a granular solid, and it has a bitter taste. It is used as an herbicide, in the production of boron, in heatresistant glassware, as a fire-resistant additive for paints, in electronics, and in liquid encapsulation techniques (Hawley's 1987, p. 162). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Animal studies indicate that eye and skin irritation were caused by the ocular instillation and the topical application, respectively, of boron oxide to the skin and eyes of rabbits. Aerosol administration at various exposure levels for varying time periods caused mild nasal irritation and an increase in urine acidity and the creatinine coefficient in dogs and rats (Wilding, Smith, Yevich et al. 1959/Ex. 1-599). Young rats that were force-fed a 10percent slurry of boron oxide in water for three weeks showed no growth retardation or other effects (Wilding, Smith, Yevich et al. 1959/Ex. 1-599).

Garabrant and co-workers (1984/Ex. 1–555) determined the prevalence of eye and respiratory irritation among boron oxide-exposed workers; the signs and symptoms of those exposed to boron oxide concentrations ranging from 1.2 to 8.5 mg/m³ were then compared with those of controls. Workers exposed to an average boron oxide concentration of 4.1 mg/m³ reported significant increases in productive cough; eye, nose, and throat irritation; dryness of the mouth; and sore throat (Garabrant, Bernstein, Peters, and Smith 1984/Ex. 1–555).

OSHA is proposing permissible exposure limits of 10 mg/m3 TWA, as total particulate, for boron oxide in the construction, maritime, and agriculture industries, retaining the 5 mg/m3 respirable fraction TWA in construction and maritime, and proposing the respirable fraction limit in agriculture. The Agency preliminarily concludes that these limits will protect workers in the construction, maritime, and agriculture industries from the significant risk of upper-respiratory-tract and eye irritation associated with exposure to this substance. OSHA believes that these health effects constitute material impairments of health and that the proposed PELs are necessary to substantially reduce these risks. In addition, promulgation of these limits will make OSHA's PELs for this

substance consistent across all regulated sectors.

CALCIUM CARBONATE CAS: 1317–65–3; Chemical Formula: CaCO₃

H.S. No. 1057

OSHA currently covers calcium carbonate in the construction and maritime industries under the Agency's generic 15-mg/m3 total particulate limit. There is no PEL in agriculture. The ACGIH has a TLV®-TWA of 10 mg/m3 for this substance, measured as total dust. In construction, maritime, and agriculture, OSHA is proposing a total particulate PEL of 15 mg/m3 as an 8hour TWA; OSHA is also retaining its 8hour 5-mg/m3 PEL for the respirable fraction in construction and maritime and proposing to extend this limit to agriculture. These are the limits recently established for calcium carbonate in general industry.

Calcium carbonate is an odorless, tasteless powder or crystalline solid that is found in limestone, chalk, marble, plant ashes, bones, and shells. This substance is used in human and animal medicine, as an ingredient in paint, rubber, plastics, dentifrices, ceramics, polishes, cosmetics, and many other

products.

Calcium carbonate is a moderate skin irritant and a severe eye irritant (Sax and Lewis 1989, p. 677). The oral LD₅₀ in rats is 6450 mg/kg (Sax and Lewis 1989, p. 677). Rabbits exposed dermally for 24 hours or ocularly for the same period developed moderate and severe

irritation, respectively.

OSHA is proposing an 8-hour TWA PEL of 15 mg/m3 for calcium carbonate (total particulate) in the construction, maritime, and agriculture industries, is retaining the 5-mg/m3 respirable particulate limit in construction and maritime, and is proposing it in agriculture. OSHA believes that these limits are necessary to protect workers in construction, maritime, and agriculture from the significant risk of physical irritation associated with exposures to calcium carbonate in the workplace. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

CALCIUM SILICATE CAS: 1344–95–2; Chemical Formula: None

H.S. No. 1061

In construction, maritime, and agriculture, OSHA has no specific limit for calcium silicate; the Agency regulates this substance in construction and maritime under its generic 8-hour TWA limit for particulates of 15 mg/m³ (measured as total particulate). The

ACGIH classifies calcium silicate as a nuisance dust and has an 8-hour TLV*-TWA of 10 mg/m³. For construction, maritime, and agriculture, the proposed total particulate PEL is 15 mg/m³, and the 5-mg/m³ limit for the respirable fraction is retained in construction and maritime and proposed in agriculture. These are the limits recently established in general industry.

Calcium silicate is a white powder.
Calcium silicate is used as an anticaking agent in table salt, foods,
pharmaceuticals, and agricultural pesticides. It is also widely used as a replacement for asbestos in thermal insulation (ACGIH 1986, p. 92.1(89); Hawley's 1987, p. 205).

No health effects other than physical irritation have been reported in humans or animals as a result of exposure to calcium silicate. Calcium silicate is thus without long-term adverse health effects if exposures are kept under reasonable control.

OSHA is retaining the 8-hour TWA PEL of 15 mg/m³, total particulate, and 5 mg/m³, respirable fraction, for calcium silicate in construction and maritime and is proposing these limits in agriculture. The Agency preliminarily concludes that these limits will protect workers in these sectors from the significant risk of physical irritation in the workplace. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

CALCIUM SULFATE
CAS: 7778–18–9; Chemical Formula:
CaSO₄

H.S. No. 1062

OSHA currently regulates calcium sulfate in the construction and maritime industries under its generic total particulate limit of 15 mg/m³. There is no PEL in agriculture. The ACGIH has a TLV*-TWA of 10 mg/m³ (total dust) for this substance. OSHA is proposing 8-hour TWA PELs of 15 mg/m³ (total particulate) and 5 mg/m³ (respirable fraction) for calcium sulfate in construction, maritime, and agriculture. These are the limits recently established for this substance in general industry.

Calcium sulfate occurs in the form of a white odorless powder or white crystals. It is used as a soil conditioner, Portland cement retarder, in quick-setting cements, molds, and surgical casts, and as a food additive (ACGIH 1986, p. 93, Hawley's 1987, p. 209). Calcium sulfate dust is reported not to have been associated with lung disease in miners (Hunter 1975). Calcium sulfate thus appears to produce no adverse effects

beyond those associated with general physical irritation.

OSHA is proposing to retain its 8-hour TWA permissible exposure limits for calcium sulfate of 15 mg/m3 (total particulate) and 5 mg/m3 (respirable particulate) in construction and maritime and to extend these limits to agriculture. The Agency preliminarily concludes that these limits are sufficient to prevent the significant risk of eye, skin, and other physical irritation in workers in these sectors and believes that these limits are necessary to reduce a significant risk. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors. CELLULOSE

CAS: 9004-34-6; Chemical Formula: (C6H10O5)n

H.S. No. 1076

OSHA currently regulates cellulose in construction and maritime under the Agency's generic 8-hour TWA total particulate limit of 15 mg/m3. There is no PEL in agriculture. The ACGIH has a TLV®-TWA of 10 mg/m3 (total dust) for this substance when it contains less than 1 percent quartz. The Agency is retaining the total particulate PEL of 15 mg/m3 as an 8-hour TWA and 5-mg/m3 limit for the respirable fraction of cellulose containing less than 1 percent quartz in construction and maritime and is proposing to extend both PELs to the agriculture sector. These are the limits recently established for cellulose in general industry.

Technical cellulose refers to that portion of the plant cell wall derived exclusively from glucose; it resembles cotton cellulose in its physical and chemical properties (ACGIH 1986/Ex. 1-3, p.113). Cellulose is used in paper. cotton products, packaging, as a source of ethanol, in medical equipment, insulation and soundproofing, and as a fuel (ACGIH 1986, p. 113; Hawley's 1987,

p. 236).

Inhalation of cellulose dust is not irritating or toxic in exposed humans if exposures are properly controlled (Schreiber 1974/Ex. 1-1096). In industry, cellulose dust occurs in combination with other substances, such as quartz dust, wood, cotton, flax, jute, and hemp fibers, and these substances have demonstrated toxicities that are unrelated to their cellulose content (ACGIH 1986/Ex. 1-3, p.113).

In construction, maritime, and agriculture, OSHA is proposing 8-hour TWA PELs for this substance of 15 mg/ m3 (total particulate) and 5 mg/m3 (respirable particulate) for cellulose dust containing less than 1 percent quartz. The Agency preliminarily concludes that these limits are necessary to protect exposed workers in these sectors from the significant risks of eye, skin, and other physical irritation. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors. 2-CHLORO-6-TRICHLOROMETHYL

PYRIDINE (NITRAPYRIN) CAS: 1929-82-4; Chemical Formula: C₆H₃CL₄N H.S. No. 1082

OSHA has no specific limit for 2chloro-6-trichloromethyl pyridine (nitrapyrin) in the construction or maritime industries, although the Agency's generic total particulate limit of 15 mg/m3 as an 8-hour TWA applies. There is no PEL in agriculture. The 1987-1988 ACGIH TLV*-TWA for nitrapyrin is 10 mg/m3 and the TLV2-STEL is 20 mg/m3. There is no NIOSH REL for this substance, but NIOSH concurs (Ex. 8-47. Table N1) with the limits being proposed. OSHA is proposing a total particulate limit of 15 mg/m3 and a respirable particulate limit of 5 mg/m3 for nitrapyrin in the construction, maritime, and agriculture industries.

for this substance in general industry. Nitrapyrin is a crystalline substance. It is used as an additive in fertilizer to control nitrification and to prevent loss of nitrogen in soil (ACGIH 1986, p. 428). Agricultural workers are thus exposed

These are the limits recently established

to nitrapyrin.

Nitrapyrin's very low vapor pressure makes hazardous inhalation exposures unlikely in the workplace. The oral LD50 in rats is 940 mg/kg, and the dermal LDso in rabbits is 850 mg/kg (RTECS 1991). Torkelson (as cited in ACGIH 1986/Ex. 1-3, p. 428) has reported feeding dogs and rats 15 mg/kg nitrapyrin daily for 93 days. He observed no adverse effects in appearance, behavior, growth, food consumption, body and organ weight, mortality, or blood chemistry, and no tissue or organ changes.

OSHA is proposing 8-hour TWA PELs of 15 mg/m3 (total particulate) and 5 mg/ m3 (respirable particulate) for this dust in the construction, maritime, and agriculture industries; OSHA preliminarily finds that these limits will be protective against the significant risk of nitrapyrin's physical irritant effects. The Agency believes physical irritation is a material health impairment. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

CLOPIDOL (COYDEN) CAS: 2971-90-6; Chemical Formula: C7H7Cl2NO H.S. No. 1095

OSHA has no specific limit for clopidol in the construction, maritime, and agriculture industries; however, OSHA's generic total particulate limit of 15 mg/ms TWA applies in construction and maritime. The ACGIH has a TLV*-TWA of 10 mg/m3 and a TLV®-STEL of 20 mg/m3 for clopidol. NIOSH has no REL for this substance. OSHA is proposing a 15-mg/m3 limit (total particulate) and 5-mg/m³ limit (respirable fraction), both as 8-hour TWAs, for clopidol in the construction, maritime, and agriculture industries. These are the limits recently established for this substance in general industry.

Clopidol is a white to light brown powder used as an anticoccidiostat in poultry (Hazardous Substance Fact Sheet 1986, p. 1; ACGIH 1986, p. 141). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

The oral LD50 for clopidol in rats, rabbits, and guinea pigs is greater than 8 g/kg (Dow Chemical Company 1973c, as cited in ACGIH 1986/Ex. 1-3, p. 141). Long-term (two-year) studies of rats and dogs fed at levels of 15 mg/kg and 5 mg/ kg per day, respectively, showed no adverse effects. Similarly, there were no adverse effects on fertility, gestation, viability, or lactation in rats and rabbits. and no increase in teratogenicity (Dow Chemical Company 1973c, as cited in ACGIH 1986/Ex. 1-3, p. 141). The chronic toxicity of clopidol is reported to be low (ACGIH 1986/Ex. 1-3, p. 141).

OSHA is proposing 8-hour TWA PELs of 15 mg/m3 (total particulate) and 5 mg/ m³ (respirable particulate) for clopidol in construction, maritime, and agriculture. OSHA preliminarily concludes that these limits will protect workers in the construction, maritime, and agriculture industries from the significant risk of eye, skin, and other physical irritation associated with exposure to clopidol. OSHA considers physical irritation a material health impairment. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors. CRAG HERBICIDE (SESONE)

CAS: 136-78-7; Chemical Formula: C8H7Cl2NaO5S

H.S. No. 1102

In construction and maritime, OSHA currently applies an 8-hour TWA limit of 15 mg/m3 for the total particulate of crag herbicide; this is the Agency's generic total particulate limit for all particulates. There is no limit in agriculture. The ACGIH has a total-dust TLV*-TWA of 10 mg/m3 for this colorless, odorless,

noncombustible solid. The proposed PELs for crag herbicide are 10 mg/m³ (total particulate) and 5 mg/m³ (respirable fraction) in the construction, maritime, and agriculture industries. NIOSH concurred (Ex. 8-47, Table N4) with OSHA in the selection of these limits when the Agency recently established them in general industry.

Crag herbicide is a colorless, odorless, noncombustible solid used commercially as an herbicide (ACGIH 1986, p. 519). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and

Rodenticide Act (FIFRA).

An early study reported an oral LDso in rats of 1500 mg/kg for this herbicide (Smyth 1956/Ex. 1-759). At high concentrations, crag herbicide is a gastrointestinal irritant (NIOSH 1984, as cited in ACGIH 1986/Ex. 1-3, p. 519). Rats fed a diet containing 60 mg sesone/ 100 gm of diet experienced minor liver damage; when fed 20 mg sesone/100 gm of diet for two years, rats showed no adverse effects (ACGIH 1986/Ex. 1-3, p. 519). In 1984, NIOSH reported the oral LDso in rats to be 730 mg/kg (NIOSH 1984, as cited in ACGIH 1986/Ex. 1-3, p. 519). In addition to physical irritation, crag herbicide can affect the central nervous system and cause convulsions in experimental animals. Acutely poisoned animals showed muscular tremor, nystagmus, and convulsions before death. Autopsy of these animals showed evidence of pulmonary hemorrhage and mild liver and kidney damage. A 5 percent solution of crag herbicide dropped into rabbits' eyes caused corneal necrosis, and 0.01 ml of a 5 percent suspension in acetone caused edema and necrosis of the skin in rabbits (Carpenter et al. 1961).

There are no reported incidents of human poisoning associated with the

use of sesone.

For construction, maritime, and agriculture, OSHA is proposing 8-hour TWA PELs for crag herbicide (total particulate) of 10 mg/m³ and 5 mg/m³ (respirable particulate). OSHA preliminarily concludes that these limits will protect workers in the construction, maritime, and agriculture industries from eye, skin, gastrointestinal, and other forms of irritation caused by exposure to crag herbicide. The Agency believes that these effects constitute material health impairments. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

DICYCLOPENTADIENYL IRON (FERROCENE) CAS: 102-54-5; Chemical Formula: C₁₀H₁₀Fe H.S. No. 1133

In construction and maritime operations, OSHA currently covers dicyclopentadienyl iron (ferrocene) under its generic 8-hour TWA total particulate limit of 15 mg/m3. There is no PEL in agriculture. The ACGIH has a TLV®-TWA of 10 mg/m3 for this substance. There is no NIOSH REL. OSHA proposes a PEL for dicyclopentadienyl iron of 10 mg/m3 (total particulate) as an 8-hour TWA in the construction, maritime, and agriculture industries and a PEL of 5 mg/ m3 (respirable fraction) as an 8-hour TWA. NIOSH (Ex. 8-47, Table N4) supports the selection of these PELs, which were recently established for dicyclopentadienyl iron in general industry.

Dicyclopentadienyl iron is a bright orange crystalline solid that smells like camphor. It is used as a combustion catalyst, as an antiknock additive for gasoline, and in polymers (Hazardous Substance Fact Sheet 1986, p. 1; ACGIH

1986, p. 195).

Available evidence in animals suggests that dicyclopentadienyl iron has a moderate order of oral toxicity but a high order of intravenous and intraperitoneal toxicity. In rats, the oral LDso is 1320 mg/kg (RTECS 1991). In rats, 500 mg/kg is the LD50 by the intraperitoneal route of administration (RTECS 1991), but subacute oral toxicity tests have shown no fatalities when 10 feedings of 200 mg/kg were given to rats over a two-week period (E.I. du Pont de Nemours and Co., Inc. 1955, as cited in ACGIH 1986/Ex. 1-3, p. 195). Daily oral administration of this substance at unspecified doses caused hemosidenosis; at a dose of 300 mg/kg for one week, dogs showed decreased hemoglobin, decreased packed cell volume, and decreased erythrocyte count (HSDB 1991). Ferrocene is mutagenic in mammalian test systems (RTECS 1991).

OSHA is proposing 8-hour TWA limits of 10 mg/m3 (total particulate) and 5 mg/ m3 (respirable fraction) for dicyclopentadienyl iron in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that these limits will substantially reduce the significant risk of material health impairments, in the form of mutagenic and other effects, that are potentially associated with occupational exposure to this substance. The Agency considers these effects material health impairments and believes that these PELs are necessary to substantially reduce these risks. In

addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

EMERY

CAS: 112-62-9; Chemical Formula: Al₂O₃

H.S. No. 1155

OSHA currently covers emery in construction and maritime under the Agency's generic 15-mg/m³ total particulate limit for all particulates. There is no PEL in agriculture. The ACGIH has a TLV*-TWA of 10 mg/m³, total dust, for emery containing less than 1 percent quartz. OSHA is proposing a total particulate PEL of 10 mg/m³ as an 8-hour TWA and a respirable fraction PEL of 5 mg/m³ for emery containing less than 1 percent quartz in the construction, maritime, and agriculture sectors. These are the limits recently established in general industry.

Emery is impure corundum (aluminum oxide) and is found in certain mineralogical deposits. Natural crystalline deposits of emery are used as abrasives; fine emery is used in lens grinding and in lapidary work (ACGIH 1986, p. 229; Hawley's 1987, p. 316).

Emery dust inhalation is believed to have contributed to a case of pneumoconiosis in France, although it is questionable whether this incident was caused by emery dust alone or by the silica impurities in the dust (Archives des Maladies Professionelles de Medecin du Travail et de Securité Sociale 1970, as cited in ACGIH 1986/ Ex. 1-3, p. 229). Exposure to emery dust containing less than 1 percent silica produces little, if any, effect on the health of exposed workers; it does not affect the lungs or produce organic disease at commonly encountered levels (ACGIH 1986/Ex. 1-3, p. 229).

Rats exposed to aluminum oxide (emery is impure aluminum oxide) developed lipoid pneumonia (Stacy, King, Harrison et al. 1959/Ex. 1–761), and humans so exposed have reported skin and respiratory tract irritation.

OSHA is proposing an 8-hour TWA PEL of 10 mg/m³ TWA, total particulate, and an 8-hour TWA PEL of 5 mg/m³, respirable particulate, for emery in construction, maritime, and agriculture. OSHA preliminarily concludes that these limits will prevent the significant risk associated with exposures to emery in the workplace; these risks include skin and upper respiratory tract irritation and, perhaps, other respiratory effects, all of which constitute material health impairments. Promulgation of these limits will also make OSHA's

PELs for this substance consistent across all regulated sectors.

FERBAM

CAS: 14484-64-1; Chemical Formula: [(CH₃)₂NCS₂]₃Fe

H.S. No. 1176

In construction and maritime, OSHA currently applies its generic particulate limit of 15 mg/m³ as an 8-hour TWA (total particulate) to ferbam. There is no PEL in agriculture. The ACGIH has a TLV*-TWA of 10 mg/m³ for this substance. In construction, maritime, and agriculture, OSHA is proposing an 8-hour TWA total particulate PEL of 10 mg/m³ for ferbam as well as an 8-hour TWA respirable fraction PEL of 5 mg/m³. NIOSH concurred (Ex. 8-47, Table N1) with these limits when the Agency recently established them for ferbam in general industry.

Ferbam is an odorless, black solid used as a fungicide on fruits, nuts, vegetables, ornamental crops, and in household applications (ACGIH 1986, p. 269; HSDB 1991). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide

Act (FIFRA).

Ferbam has been reported to have an oral LD₅₀ of more than 17 mg/kg in rats, but rabbits and guinea pigs demonstrated less sensitivity to this substance (Hodge, Maynard, Downs, and Blanchet 1952/Ex. 1–861). Dogs showed no adverse effects when fed 25 mg/kg of ferbam daily for six months.

In addition to physical irritation, ferbam can cause skin sensitization, gastrointestinal effects, and reproductive effects in experimental animals. The offspring of pregnant rats exposed to high but sublethal doses of ferbam showed evidence of embryo/fetotoxicity (IARC 1982, Vol. 12, pp. 121–129). Ten of 20 rats died after ingesting a diet containing 0.5 percent ferbam for 30 days; autopsies revealed minor lung, liver, kidney, and bone marrow abnormalities in a few of these animals (Hodge et al. 1952).

Inhalation of ferbam affects the upper respiratory tract in humans in the manner typical of airborne exposures to workplace dusts (Hodge, Maynard, Downs, and Blanchet 1952/Ex. 1–861). The dust of ferbam is irritating to the eyes, nose, throat, and skin (Grant 1986, p. 431). Large oral doses of ferbam can cause gastrointestinal disturbances in humans (AMA Council on Pharmacy and Chemistry 1955, from Proctor, Hughes, and Fischman 1988, p. 257). Ferbam dust can be irritating to the skin and mucous membranes and may cause

skin sensitization (Gosselin, Smith, and Hodge 1984, p. II-311).

OSHA is proposing a total particulate PEL for ferbam of 10 mg/m3 as an 8-hour TWA and a respirable fraction PEL of 5 mg/m3 as an 8-hour TWA. The Agency preliminarily concludes that these limits are necessary to prevent the significant health and safety risks associated with exposures to ferbam in the construction, maritime, and agriculture industries. These risks include skin, eye, and upper respiratory tract irritation, which OSHA considers material health impairments. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors. GLYCERIN (MIST) CAS: 56-81-5; Chemical Formula:

CH₂OHCHOHCH₂OH

H.S. No. 1188

In construction, maritime, and agriculture, OSHA has no specific limit for glycerin mist, although this substance has been regulated in construction and maritime under the Agency's generic total particulate limit. The ACGIH has a TLV®-TWA of 10 mg/m³ (total particulate) for glycerin. OSHA is proposing a total particulate PEL of 10 mg/m³ and a respirable fraction PEL of 5 mg/m³ for glycerin mist in construction, maritime, and agriculture. These are the limits recently established for glycerin in general industry.

Glycerin is an oily, hygroscopic liquid with a warm, sweet taste. Glycerin is widely used to manufacture plastics, cosmetics, foodstuffs, confectioneries, explosives, pharmaceuticals, perfumes, inks, lubricants and softeners, and antifreeze mixtures (ACGIH 1986, p. 286;

Hawley's 1987, p. 568).

Glycerin was long considered to be nontoxic; however, there are indications that the mist may be injurious to the kidneys at very high exposure levels (Campanacci 1965/Ex. 1-1047). In addition to physical irritation and kidney effects, glycerin can affect the central nervous system, reproductive system, and gastrointestinal tract in experimental animals. Mice exposed to 8800 mg/kg glycerin experienced convulsions and skin effects (RTECS 1991). Male rats given 2-day intratesticular doses of 280 mg/kg and a 1-day dose of 1600 mg/kg showed changes in fertility (Wiebe and Barr 1984). Rabbits suffered mild skin irritation at a dermal dose of 500 mg glycerin for 24 hours and experienced mild eye irritation after 126 mg of glycerin was put into their eyes (RTECS

An oral dose of 1428 mg/kg glycerin caused headaches and gastrointestinal effects in humans (RTECS 1991).

Although glycerin's toxicity is generally considered to be low, large doses can cause hemolysis, hemoglobinuria, renal failure, convulsions, and paralysis in humans (Ex. 8-47). Oral doses of glycerin administered for therapeutic purposes can cause side effects such as headache, dizziness, vomiting, diarrhea, and fever (Gosselin, Smith, and Hodge 1984, p. II-226).

OSHA is proposing 8-hour TWA limits of 10 mg/m3 (total particulate) and 5 mg/ m3 (respirable particulate) for glycerin mist in construction, maritime, and agriculture. The Agency preliminarily concludes that these limits will provide protection for workers in these sectors against the significant risks of glycerin exposure, which include possible kidney damage and blood effects. OSHA believes that these effects constitute material health impairments and that the proposed limits are necessary to substantially reduce these risks. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

GRAPHITE, SYNTHETIC CAS: None; Chemical Formula: None H.S. No. 1191A

OSHA currently has no specific limit for synthetic graphite in construction and maritime, although this substance is covered under the Agency's generic total particulate limit. There is no PEL in agriculture, and NIOSH has no REL. The ACGIH has a TLV*-TWA of 10 mg/m³ for graphite as total dust. OSHA is proposing PELs of 10 mg/m³ and 5 mg/m³ for the total and respirable particulate, respectively; these are the limits recently established for synthetic graphite in general industry.

Synthetic graphite is a crystalline form of carbon made from the high-temperature treatment of coal or petroleum products; it has the same properties as natural graphite. Synthetic graphite is used in place of natural graphite in refractories and in electrical uses (ACGIH 1986, p. 291).

Meiklejohn reported in 1958 that synthetic graphite injected intraperitoneally in mice produced effects characteristic of those of the inert dusts (Meiklejohn 1958).

In humans, exposure to natural graphite has long been associated with the development of pneumoconiosis (Koopman 1924/Ex. 1–131; Ruttner, Bovet, and Aufdermauer 1952/Ex. 1–661; Pendergrass, Vorwald, Mishkin et al. 1967/Ex. 1–77). Lister (1961/Ex. 1–422) and Lister and Wimborne (1972/Ex. 1–423) reported fibrotic changes in the

lungs of a worker who had been engaged for 17 years in the production and milling of synthetic graphite. Other reports of lung injury caused by exposure to graphite have not distinguished between the form of the graphite (i.e., natural or synthetic) causing the injury; in addition, exposures to impurities, such as quartz silica, were involved in many of the reported cases (ACGIH 1986/Ex. 1-3, p. 291). In the prior rulemaking, NIOSH (Ex. 8-47) commented that, in its opinion, it is not appropriate to distinguish between the natural and synthetic forms of graphite and noted that the Lister and Wimborne (1972/Ex. 1-423) study described above suggests that synthetic graphite dust exposure "is capable of producing pneumoconiosis." NIOSH believes that a 2-mg/m3 8-hour TWA PEL is appropriate for synthetic graphite because this is the limit set for coal dust (respirable) to protect against pneumoconiosis (Ex. 8-47). However, because the primary objective of this proposed rule is to make OSHA's limits consistent across all industry sectors, OSHA intends as a first step to propose in construction, maritime, and agriculture the limits recently established for graphite in general industry. At the time of the first PEL update, OSHA will consider the recent toxicological literature on graphite to evaluate whether a lower limit should be considered.

At present, however, OSHA is proposing an 8-hour TWA total particulate limit for synthetic graphite of 10 mg/m3 and an 8-hour TWA respirable fraction limit of 5 mg/m3 to protect workers in construction, maritime, and agriculture against the significant health risks associated with graphite exposures in the workplace. OSHA preliminarily concludes that these limits are necessary to substantially reduce the risks of graphite-induced respiratory disease, which constitutes a material impairment of health. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

GYPSUM CAS: 7778–18–9; Chemical Formula: CaSO₄ H₂O H.S. No. 1192

The current OSHA limit for gypsum in general industry, construction, and maritime is an 8-hour TWA of 15 mg/m³. There is no PEL in agriculture. The ACGIH has a TLV*-TWA of 10 mg/m³, measured as total particulate. OSHA is proposing to extend the 8-hour TWA PELs for gypsum of 15 mg/m³ (total particulate) and 5 mg/m³ (respirable

particulate) to workplaces in agriculture. These are the limits recently established for gypsum in general industry.

Gypsum is found either as colorless or white crystals. Gypsum finds use in soil treatment, the manufacture of Plaster of Paris and Portland cement, in the production of heavy chemicals, in water clarification, and in animal feed. There is also a food and pharmaceutical-grade gypsum that is used as a source of calcium (ACGIH 1986, p. 93).

The ACGIH (1986/Ex. 1-3) states that gypsum does not "produce significant organic disease or toxic effect when exposures are kept under reasonable control." Exposures in excess of the proposed limit may result in reduced visibility, deposits of gypsum dust in the eyes, ears, and nasal passages, and skin irritation.

In agriculture, OSHA is proposing 8-hour TWA PELs for gypsum of 15 mg/m³ (total particulate) and 5 mg/m³ (respirable fraction). The Agency preliminarily concludes that these limits will protect workers in this sector from the significant risk of eye, skin, and other forms of physical irritation caused by gypsum exposure. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors. KAOLIN

CAS: None; Chemical Formula: H₂Al₂Si₂O₈O • H₂O H.S. No. 1230

OSHA's current limit for kaolin in construction and maritime is 15 mg/m³, measured as total particulate; this is the Agency's generic total particulate limit for all dusts and particulates. There is no PEL for agriculture. The ACGIH has a TLV®-TWA for kaolin of 10 mg/m³, measured as total dust. OSHA is proposing 8-hour TWA PELs for kaolin of 10 mg/m³ (total particulate) and 5 mg/m³ (respirable fraction) in construction, maritime, and agriculture. These are the limits recently established for kaolin in general industry.

Kaolin takes the form either of a white powder or a white or yellow-white earthy mass. Kaolin is used for filler and coatings for paper and rubber; in refractories, ceramics, cements, fertilizers, chemicals, anticaking preparations, cosmetics, insecticides, and electrical insulators. It is also used as a catalyst carrier, a source of alumina, and an adsorbent for the clarification of liquids (Hawley's 1987, p.

Exposure to excess amounts of kaolin dust may cause injury to the skin and mucous membranes (ACGIH 1986/Ex. 1-3). NIOSH (Ex. 8-47, Table N4) also notes that exposure to kaolin dust has

been associated with respiratory effects (Lapenas and Gale 1983).

In construction, maritime, and agriculture, OSHA is proposing 8-hour TWA PELs of 10 mg/m3 (total particulate) and 5 mg/m3 (respirable particulate) for kaolin. The Agency preliminarily concludes that these limits will protect workers in these sectors from the significant health risks associated with exposure to this substance. These risks include skin and mucous membrane injury, and, perhaps, irreversible respiratory effects, all of which constitute material health impairments. In addition, promulgation of these limits will make OSHA's PELS for this substance consistent across all regulated sectors.

LIMESTONE

CAS: 1317-65-3; Chemical Formula: CaCO₃

H.S. No. 1232

In construction and maritime, the current generic particulate PEL for limestone is an 8-hour TWA of 15 mg/m³, measured as total particulate. There is no PEL in agriculture. The ACGIH has a 10-mg/m³ TWA for limestone (total particulate). OSHA is proposing 15 mg/m³ as the 8-hour TWA PEL for total limestone particulate and 5 mg/m³ as the 8-hour TWA for the respirable fraction in construction, maritime, and agriculture; these are the limits recently established for limestone in general industry.

Limestone is rock formed by the accumulation of organic remains that consist of calcium carbonate and, less often, magnesium carbonate. Limestone finds use in metallurgy, building stone, agriculture, as a source of carbon dioxide, in cement, alkali manufacture, and in the removal of sulfur dioxide from stock gases and sulfur from coal (Hawley's 1987, p. 701).

Direct contact with limestone dust at unspecified levels has been associated with the development of severe eye irritation and moderate skin irritation (Sax and Lewis 1989). The application of 500 mg limestone to the skin of rabbits for 24 hours produced moderate irritation, and 750 mg instilled into the eves of rabbits caused severe irritation (RTECS 1990). The oral LDse in rats is 6450 mg/kg (RTECS 1990). In the earlier rulemaking, the American Iron and Steel Institute (Exs. 3-1123 and 8-22) argued that limestone dust produces effects that are "short-term and immaterial" (Ex. 8-22, pp. 29-30); however, OSHA does not agree that the physical irritant effects caused by exposure to dusts and particulates are not material impairments; such irritation affects the

skin, eyes, nose, upper respiratory tract, and mucous membranes adversely.

In construction and maritime, OSHA is retaining 8-hour TWA limits of 15 mg/m³ (total particulate) and 5 mg/m³ (respirable particulate) for limestone; the Agency is also proposing to extend these limits to agriculture. OSHA preliminarily concludes that these limits will protect workers in these sectors from the significant risk of eye and skin irritation that may be experienced by employees exposed to limestone in the workplace. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

MAGNESITE

CAS: 546-93-0; Formula: (MgCO₃)₄ • Mg(OH)₂ 5H₂O (approx.) H.S. No. 1233

In construction and maritime, OSHA's current PEL for magnesite is 15 mg/m³, measured as total particulate; this is the Agency's generic limit for all dusts and particulates. There is no PEL in agriculture. The ACGIH has a TLV*-TWA of 10 mg/m³, also measured as total particulate. The proposed PELs for magnesite are 8-hour TWAs of 15 mg/m³ (total particulate) and 5 mg/m³ (respirable fraction); these limits would apply in construction, maritime, and agriculture. These are the limits recently established for this substance in general industry.

Magnesite occurs as a white powder. It is used to produce various grades of magnesium oxide, to make carbon dioxide, and as an ingredient in refractories (Hawley's 1987, p. 718).

Magnesite is considered by both OSHA and the ACGIH to be one of the dusts that "do not produce significant organic disease or toxic effect when exposures are kept under reasonable control" (ACGIH 1986/Ex. 1-3). Exposure to excess levels of magnesite in the workplace causes skin or mucous membrane irritation resulting either from contact with the magnesite itself or from the rigorous cleansing procedures necessary for removing the dust.

In construction and maritime, OSHA is retaining its 8-hour TWA PEL of 15 mg/m³ TWA for magnesite, measured as total particulate, and its 8-hour TWA PEL of 5 mg/m³ measured as the respirable fraction; the Agency is proposing to extend these limits to agriculture, OSHA preliminarily concludes that these limits will protect workers in these sectors from the significant risk of skin, mucous membrane, and other physical irritation. In addition, promulgation of these limits will make OSHA's PELs for this

substance consistent across all regulated sectors.

MAGNESIUM OXIDE (FUME) CAS: 1309-48-4; Chemical Formula: MgO H.S. No. 1234

In construction and maritime, OSHA's current limit for magnesium oxide (as fume) is 15 mg/m³ as an 8-hour TWA, the Agency's generic limit for particulates. There is no PEL in agriculture. The ACGIH has a TLV²-TWA limit of 10 mg/m³ for magnesium oxide fume. OSHA is proposing 8-hour TWA PELs of 10 mg/m³ (total particulate) and 5 mg/m³ (respirable particulate) for magnesium oxide fume in construction, maritime, and agriculture. These are the limits recently established for this substance in general industry.

Magnesium oxide is a very fine white, odorless powder. Magnesium oxide fume is produced during the burning of magnesium. Magnesium oxide in powder form is used in ceramics, pharmaceuticals, as an acid neutralizing agent, as a food additive, and in fertilizers (ACGIH 1986, p. 351; Hawley's 1987, p. 721).

Slight reactions (not further specified) have been reported in human subjects after exposures of less than 10 minutes to freshly generated MgO fume at concentrations of from 400 to 600 mg/m3 (Drinker, Thomson, and Finn 1927/Ex. 1-356). Animal and human studies of magnesium oxide fume exposure have shown toxicities less marked than but similar to those attributable to zinc oxide fume (Drinker and Drinker 1928/ Ex. 1-314). The symptoms of exposure include those of metal fume fever (fever. chills, muscular pain, nausea, and vomiting) and leukocytosis, symptoms analogous to those caused by exposure to zinc oxide fume. NIOSH notes that exposure to magnesium oxide may also cause chronic respiratory disease (Ex. 8-

In construction, maritime, and agriculture, OSHA is proposing PELs of 10 mg/m3 TWA (total particulate) and 5 mg/m3 TWA (respirable fraction) for magnesium oxide fume. OSHA preliminarily concludes that these limits will substantially reduce the significant risks of metal fume fever, leukocytosis, and, perhaps, chronic respiratory disease associated with exposure to magnesium oxide fume in the workplace. OSHA believes that these health effects constitute material health impairments and that the proposed PELs will substantially reduce these risks. In addition, promulgation of these limits will make OSHA's PELs for this

substance consistent across all regulated sectors.

MALATHION
CAS: 121-75-5; Chemical Formula:
C₁₀H₁₉O₆PS₂
H.S. No. 1235

In construction and maritime, OSHA currently has a 15-mg/m3 total particulate limit (8-hour TWA) for malathion, with a skin notation. OSHA has no PEL in agriculture. The ACGIH TLV*-TWA for this substance is 10 mg/ m3, also with a skin notation, and the NIOSH REL is 15 mg/m3. OSHA has no PEL in agriculture. OSHA is proposing an 8-hour TWA PEL of 10 mg/m3 (total particulate) and 5 mg/m³ (respirable fraction) in the construction, maritime, and agriculture sectors. These are the limits recently established for malathion in general industry. NIOSH (Ex. 8-47, Table N4) concurs with the selection of these limits.

Malathion is a noncombustible, yellow to deep brown liquid with a skunk-like odor. Malathion finds use as an insecticide for fruits, vegetables, and ornamental plants (Clayton and Clayton 1981, p. 4825). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

In addition to physical irritation, malathion causes effects related to cholinesterase inhibition, including headaches, labored breathing, vomiting, tremors, and cardiovascular effects. The oral LD50s for mice and rats are 507 mg/ kg and 370 mg/kg, respectively (RTECS 1991). Malathion is a widely used organophosphorus insecticide having a relatively low level of toxicity; some authors have determined that malathion is approximately 1/100th as toxic as parathion (Johnson, Fletcher, Nolan, and Cassaday 1952/Ex. 1-149). Rats fed malathion at a concentration of 100 ppm for two years exhibited no toxic effects [Hazleton and Holland 1953/Ex. 1-126]. Several occupational and research studies involving human volunteers have shown that malathion exposure produced no changes in blood cholinesterase or other effects (Rider, Mueller, Swader et al. 1959/Ex. 1-189; Hayes, Mattson, Short, and Witter 1960/ Ex. 1-90; Culver, Caplan, and Batchelor 1956/Ex. 1-177). Fatalities have been reported in the Japanese and Indian literature, but these deaths have always involved extremely high doses of malathion (Chabra 1970/Ex. 1-151; Horiguchi 1973/Ex. 1-221).

In the prior rulemaking, one commenter (Ex. 3-678) questioned the need for a skin notation for a substance

with a dermal LD50 of 200 mg/kg or less in animal tests when there was no evidence of systemic effects in humans as a result of skin contact (Ex. 3-678, p. 3). OSHA explained to this commenter that its policy is to use a dermal LD50 in rabbits of 1000 mg/kg as an indicator of dermal toxicity; this is the Hazard Communication standard's upper cutoff for a toxic, rather than highly toxic, substance administered by the dermal route (see Section VI.C.16 of this preamble for a discussion of OSHA's reasoning on this issue). In addition, OSHA believes that evidence that a substance has caused systemic toxicity in humans exposed via the dermal route is sufficient reason to retain a skin notation; in the case of malathion. OSHA has received reports of exposed workers whose blood cholinesterase levels were reduced after dermal exposure to this substance. OSHA is therefore retaining the skin notation for malathion in the proposed rule.

In construction, maritime, and agriculture, OSHA is proposing PELs of 10 mg/m³ TWA (total particulate) and 5 mg/m³ TWA (respirable particulate) for malathion, with a skin notation. The Agency preliminarily finds that exposure to malathion poses a significant risk of material health impairment in the form of cholinesterase inhibition. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

MARBLE

CAS: 1317–65–3; Chemical Formula: None H.S. No. 1239

In construction and maritime, OSHA currently has no specific limit for marble dust, although this substance is currently covered under the generic total particulate limit of 15 mg/m³. There is no PEL in agriculture. The ACGIH has established an 8-hour TLV*-TWA of 10 mg/ms for marble dust containing less than 1 percent quartz (measured as total dust). OSHA is proposing to retain its 8hour TWA limits for marble dust of 15 mg/m³ as total particulate containing less than 1 percent quartz and 5 mg/m3 as the respirable fraction in construction and maritime, and to extend both limits to agriculture. These are the limits recently established for marble in general industry.

Marble dust, a metamorphic form of calcium carbonate dust, is an odorless and tasteless powder or crystal. Marble is used as a source of carbon dioxide in laboratory experiments and as building stone, monumental stone, ashlar, veneer panelling, wainscotting, and tiling

(Hawley's 1987, p. 732, Parmeggiani 1983, p. 1284).

There are no toxicity data in animals for marble dust. Exposure to this substance causes physical irritation of the eyes, nose, mucous membranes, and skin (Genium MSDS 1977).

In the proposed rule, OSHA is retaining its former total particulate limit for marble of 15 mg/m³, as well as the respirable particulate limit of 5 mg/m³ in construction and maritime and is proposing to extend these limits to agriculture. OSHA preliminarily finds that these limits will protect exposed workers in these sectors against the significant risk posed by the physical irritant properties of marble. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors. METHOXYCHLOR

CAS: 72-43-5; Chemical Formula:

C₁₆H₁₅C₁₃O₂ H.S. No. 1246

In construction and maritime, OSHA currently applies its generic 15-mg/m³ TWA limit for particulates to methoxychlor. There is no limit in agriculture. The ACGIH recommends a limit of 10 mg/m³ TWA for methoxychlor. OSHA is proposing a 10 mg/m³ limit for the total particulate of methoxychlor and a 5 mg/m³ limit for the respirable fraction in construction, maritime, and agriculture. NIOSH (Ex. 8-47, Table N4) concurs with the selection of these limits, which are identical to those recently established in general industry.

Methoxychlor is a white crystalline solid used as an insecticide on fruit and shade trees, vegetables, dairy and beef cattle, home gardens, and farm buildings (except poultry houses) (Farm Chemicals Handbook 1990, p.C191; ACGIH 1986, p. 364). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

The reported oral LD50 for methoxychlor in rats is 6000 mg/kg (Lehman 1954, as cited in ACGIH 1986/ Ex. 1-3, p.364). Lehman also determined that 100 ppm for two years is the lowest dietary level producing no effect in rats; this corresponds to a level of 350 mg/ man/day (Lehman 1954, as cited in ACGIH, 1986/Ex. 1-3, p. 364). Results of another dietary study indicated that rats fed 200 ppm methoxychlor for two years were not affected in terms of growth or survival (Hodge, Maynard, and Blanchet 1952/ Ex. 1-488). Tegeris and co-workers (1966/Ex. 1-389) reported that dogs fed 1 g/kg daily for 6 months showed weight

loss; most animals died within nine weeks when the dietary level was increased to 2 g/kg daily (Tegeris, Earl, Smalley, and Curtis 1966/Ex. 1-389). Morgan and Hickenbottom (1978/Ex. 1-351) reported that male Holtzman rats fed 10, 40, 160, or 640 mg/kg for 24 hours showed no liver abnormalities. Extrapolating from animal data, Lehman (1954) estimated the dose levels that would produce toxic effects in humans as follows: the fatal oral dose would be 450 grams; adverse health effects would occur at 6430 mg/kg orally; and 2414 mg/kg is the level at which dermal effects would be predicted to occur (Lehman 1954). Methoxychlor has been tested in carcinogenicity bioassays and the results have not provided sufficient evidence to determine the carcinogenicity of methoxychlor in animals (Sax and Lewis 1989).

In construction, maritime, and agriculture, OSHA is proposing 8-hour TWA limits for methoxychlor of 10 mg/m³ (total particulate) and 5 mg/m³ (respirable fraction). The Agency believes that these limits are necessary to reduce the significant health risks of systemic toxicity, which constitutes a material impairment of health within the meaning of the Act. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

MOLYBDENUM (INSOLUBLE COMPOUNDS)

CAS: 7439–98–7; Chemical Formula: Insoluble compounds H.S. No. 1278

In construction and maritime, OSHA currently has a limit of 15 mg/m3 TWA for the insoluble compounds of molybdenum, which include molybdenum metal dust and the dioxide; this is the Agency's generic limit for all particulates. There is no limit in agriculture. The ACGIH recommends a TLV*-TWA of 10 mg/m3; measured as molybdenum, for these substances. NIOSH has no REL. OSHA is proposing PELs of 10 mg/m3 TWA (total particulate) and 5 mg/m3 (respirable particulate) for the insoluble compounds of molybdenum, measured as molybdenum, in construction, maritime, and agriculture. These are the limits recently established for these compounds in general industry.

Molybdenum is a silver-white metal or a dark gray or black powder. The soluble molybdenum compounds include molybdenum trioxide, ammonium molybdate, the hexammonium salt of molybdic acid, and dihydrated sodium molybdate. Molybdenum trioxide is used as a source of molybdenum

compounds, in agriculture, pigments, ceramic glazes, and as a catalyst. Ammonium molybdate is used in pigments, as an analytical reagent, and in coal technology. The hexammonium salt of molybdic acid is used as an intermediate in the manufacture of pigments, as a component of fertilizers, and as a reagent in chemistry. Sodium molybdate finds use in the manufacture of pigments, as a bath additive for metal finishing, and as a micronutrient for plants and animals (Merck 1983, p. 79, 1238; Hawley's 1987, p. 68, 795).

Mogilvskaya [1950, as cited in ACGIH 1986/Ex. 1-3, p. 415) reported that the dust of molybdenum metal and molybdenum dioxide caused irritation of the mucosal surfaces in white mice after an intensive dusting for one hour; in a similar 30-day exposure, the metal and the dioxide proved only minimally poisonous. Molybdenum trioxide at 100 mg/kg/day was lethal to rats, and exposure to this substance by inhalation caused eye and nose irritation in these animals and was subsequently lethal (HSDB 1991). Molybdenum trioxide was also weakly tumorigenic (lung tumors) in Strain A mice after injection (Shimkiu et al. 1978). Rats given 1.2 g/kg ammonium molybdate orally showed trembling. signs of colic, incoordination, and dyspnea (Browning 1969).

The insoluble compounds of molybdenum are generally acknowledged to have a low order of toxicity; however, there is some evidence that respiratory effects have been caused by exposure to these compounds (Browning 1961b, Friberg and Lener 1988, Stokinger 1981d). Exposure to molybdenum trioxide is known to cause severe irritation of the eyes and mucous membranes (Parmeggiani 1983). Three of 19 workers exposed to molybdenum and molybdenum trioxide developed pneumoconiosis after 4 to 7 years of exposure to concentrations ranging from 1 to 19 mg/m³ (Parmeggiani 1983).

In construction, maritime, and agriculture, OSHA is proposing PELs for the insoluble compounds of molybdenum, measured as molybdenum, of 10 mg/m3 TWA [total particulate) and 5 mg/m3 TWA (respirable particulate). The Agency preliminarily concludes that these limits will protect workers in these sectors from the significant health risks of exposure to the insoluble compounds of molybdenum, which include eye, nose, and skin irritation, and may include chronic respiratory effects. OSHA believes that these effects constitute material health impairments and that the proposed limits are necessary to

substantially reduce the risk of these effects. In addition, promulgation of these limits will make OSHA's PELs for these substances consistent across all regulated sectors.

PARTICULATES (NOT OTHERWISE REGULATED)

CAS: None; Chemical Formula: None H.S. No. 1294

In construction and maritime, OSHA currently covers all otherwise unregulated particulates under a single 8-hour TWA PEL of 15 mg/m³ (measured as total particulate) and a single 8-hour TWA PEL of 5 mg/m³ (measured as the respirable fraction). The ACGIH has a TLV°-TWA of 10 mg/m³ (as total dust) for all not-otherwise-classified particulates having a quartz content of less than 1 percent.

OSHA is proposing to extend the permissible exposure limits (PELs) for Particulates Not Otherwise Regulated (PNORs) that were recently retained in general industry, which are 8-hour TWAs of 15 mg/ms (total particulate) and 5 mg/m3 (respirable fraction) to workplaces in the agricultural sector. OSHA is retaining these limits for workplaces in construction and maritime but changing the name given to this group of substances from "nuisance dusts" to particulates not otherwise regulated and making it clear that these limits apply to organic as well as inorganic dusts. OSHA has established PELs for particulates not otherwise regulated based on their ability to cause physical irritation of the eyes, skin, mucous membranes, and upper respiratory tract. In the earlier rulemaking, OSHA did not consider or discuss other adverse health effects caused by exposure to the PNORs. The following discussion summarizes more recent information and studies on adverse health effects that result from exposure to the so-called "nuisance," or inert dusts. This information demonstrates that these dusts have health effects and that the term "nuisance" is indeed inappropriately applied to them.

The term "lung overload" denotes a series of general responses of the pulmonary system to the presence of large quantities of respirable, insoluble, and relatively benign dusts that are retained for extended periods of time in the lungs (Muhle et al. 1989). The mechanism thought to be responsible for this phenomenon is impaired clearance. Morrow (Fundamental and Applied Tox, 1988, Possible Mechanisms to Explain Dust Overloading of the Lungs, p. 369) hypothesizes that dust overloading reflects a breakdown in alveolar macrophage (AM)-mediated dust

removal caused by the loss of AM mobility. The inability of dust-laden AMs to translocate to the mucociliary escalator correlates with the average composite particle volume per alveolar macrophage in the lung; when the distributed particulate volume exceeds a specific volume, the evidence suggests that AM-mediated particle clearance virtually ceases, causing particle-laden macrophages to remain in the alveolar region. A number of theories have been advanced to explain how these particle-laden cells become immobilized.

Even dusts thought to be benign can cause lung overload, which appears to be dependent on the amount of dust in the lung rather than the particular type of dust. Dust overload occurs when the amount of dust present overwhelms the ability of the macrophages (a type of white blood cell) to engulf and digest or move the dust particles. A wellfunctioning phagocyte engulfs dust and other foreign particles, and either digests them or moves them toward the bronchus and up the trachea so that they can be spit out or swallowed. When dust overload occurs, clearance of these particle-laden macrophages is reduced, and they remain deep in the lung. These retained particles then further reduce the ability of the lung to function normally.

To investigate lung response to high molecular weight polymers (considered biologically inert), Muhle et al. 1989 (H. Muhle, R. Mermelstein, C. Dasenbrock, S. Takenaka, U. Mohr, R. Klipper, J. MacKenzie and P. Morrow, Lung response to test toner upon 2-year inhalation in rats, Exp. Pathol. 1989; 37:239-242) exposed rats to a special test toner (35% respirable) at 0, 1, 4, or 16 mg/m3, to titanium dioxide (TiO2) at 5 mg/m³, or to silica (SiOa) at 1 mg/m³ for 8 hours/day, 5 days/week for up to 24 months. No changes in any pulmonary parameter were observed in the rats exposed to the toner at the low exposure level. In the toner mid-exposure group, a very slight to slight degree of fibrosis was detected in 20% of the rats at the termination of the study. In the toner high-exposure group, fibrosis of slight degree was observed in 65% of the animals and a moderate degree of fibrosis was seen in 18% of the rats. In the TiO2-exposed rats, a 5% prevalence of lung fibrosis was observed. Based on the volume of TiOz retained in the lungs in this study and on comparison with published values, the fibrogenic potency of the test toner and TiO, were

In the SiO₂ (positive control) group, a moderate degree of lung fibrosis was detected in 85% of the animals and a

calculated to be comparable.

slight degree of fibrosis was observed in 14% of these rats at the termination of the study. Lipoproteinaceous material in the alveoli was detected in the alveoli in many of the animals at final sacrifice, predominantly in the toner highexposure and silica exposure groups. The authors concluded that the various lung changes observed in the toner highexposure rats and to a lesser extent in the toner mid-exposure animals (including the proteinosis) are identical to the characteristic signs of lung overloading. The authors also stated that, since the observed pulmonary changes are not uniquely associated with a specific test toner, their findings are likely to be applicable to other toners and to other relatively non-toxic respirable dusts as well.

In a subsequent study, Muhle et al. (H. Muhle, B. Bellman, O. R. Klipper, J. MacKenzie, R. Mermelstein, Subchronic Inhalation Study of Toner in Rats, Inhalation Toxicology, 2:341–360, 1990, p. 341–359) exposed rats to special (35% respirable) test toner at 0, 1, 4, 16, or 64 mg/m³ for 6 hours/day, 5 days/week for 13 weeks. No exposure-related effects were seen in the test animals in terms of survival or causes of death, clinical chemistry or hematology parameters, or systemic or upper respiratory system effects. Exposure also caused no alteration in tumor frequency.

Significant pulmonary responses were seen in the rats exposed at the middle and high dose levels. At 16 mg/m³, some indications of retarded lung clearance were noted and, at 64 mg/m³, no appreciable clearance of toner was detected. Seventy-five days after the 90-day exposure interval, test toner was retained in the lungs of the rats in the 4, 16, or 64 mg/m³ groups in the ratio of 1: 10.3: 77, compared with the theoretical toner input ratio of 1: 4: 16.

The authors attributed the pulmonary changes observed at the two highest exposure levels to "lung overload." Based on the results of this study, the authors stated that both the maximum tolerated dose (MTD) and the maximum functionally tolerated dose (MFTD) of test toner were exceeded at the 64 mg/

m³ exposure level.

At a symposium organized by the International Society of Aerosols in Medicine (ISAM) and Environmental Health Sciences Center (EHSC) of the University of Rochester and held in Rochester, New York (May 17 and 18, 1990), Mermelstein and Klipper, scientists from the Xerox Corporation, presented a poster session, entitled "Particle-Lung Interactions: 'Overload' Related Phenomena." These authors also presented a paper entitled, "Xerox exposure limit for respirable dust"

(N.O.S.) (Paper 406) at the 1990
American Industrial Hygiene
Conference (AIHC), May 21–25, in
Orlando, FL. Mermelstein and Klipper
conducted a chronic inhalation study of
toner in rats (discussed above) and then
performed a recovery study to determine
the reversibility of the pulmonary
changes observed in rats after both
acute (8 days) and subchronic (13
weeks) exposure.

To simulate an acute overexposure situation, the rats were exposed to 40 mg/m³ (high level) of the test toner for 8 days. In the main recovery study, female rats were exposed either to 0 mg/m³ (control), 10 mg/m³ (low), or 40 mg/m³ (high) concentrations of toner for 13 weeks, followed by four 13 week

observation intervals.

The general results of the recovery study paralleled those of the subchronic study. In the high-dose 8-day exposure group, a slight inflammatory response was seen at the end of exposure, but the lungs returned to normal within 90 days post-exposure. In the low dose 13-week exposure group, the slight inflammatory response observed returned to normal within 180 days but the slight decrease in clearance persisted through the 15 month post-exposure period. In the high dose 13-week exposure group, a moderate inflammatory response and a decrease in clearance, both symptoms of overloading, were observed. At the end of the 15-month post-exposure period, animals in this group continued to show a decrease in clearance: the authors described these effects as "extensive symptoms of overloading." In addition, very slight fibrosis was present in the lungs of 2 of the 5 animals in the highdose subchronic group.

Researchers have attempted to correlate published accounts in the toxicologic literature that document "lung overload" in animals with the human experience. Cotes and Steel described the progressive nature of lung overload in coal miners (1987, Work-Related Lung Disorders, Blackwell Scientific Publications, Oxford, p. 178, as reported in Mermelstein and Klipper,

Paper #406: 1990 AIHC):

Coal miners and others who breathe air contaminated with coal dust retain some dust in their lungs. The dust accumulates in small foci or macules which constitute simple pneumoconiosis of coal workers * * *. Simple pneumoconiosis is not associated with respiratory symptoms, does not shorten life and in the absence of chest radiograph may not even be suspected. However, with passage of time, following heavy dust exposure one or more macules enlarge or a number coalesce to form progressive massive fibrosis (PMF); the lesions progressively disrupt the normal function of the lung, give rise to respiratory symptoms and reduce life

expectancy. This sequence constitutes classical pneumoconiosis of coal workers.

Morrow et al. (Morrow, Muhle, Mermelstein, 1991, Chronic Inhalation Study Findings as a Basis for Proposing a New Occupational Dust Limit, Journal of the American College of Toxicology) assumes that there may be a human counterpart to the dust overloading seen in animals that occurs at the same milligram dust per gram lung concentration. Applying extrapolation modeling to determine a likely correlate value for humans, these authors conclude that an exposure limit of 1 mg/ ms, measured as respirable dust, would be appropriate in industrial settings. Based on these considerations, Xerox Corporation has established an internal respirable dust limit of 0.4 mg/m3.

Pulmonary Alveolar Proteinosis

Pulmonary alveolar proteinosis (PAP). also referred to as phospholipidosis, is a syndrome that occurs as a result of the abnormal accumulation of surfactant phospholipids and proteins in the alveolar spaces of the lung. This condition was first described by Rosen et al. in 1958. Since then, numerous case reports have appeared in the literature. The symptoms of PAP are similar to those of other progressive restrictive lung diseases: nonproductive cough, progressive dyspnea on exertion, and fatigue. Depending on the severity of the disorder, weight loss, hemoptysis, chest pain, and fevers may be experienced. No single etiologic agent has been identified. In fact, the broad spectrum of etiologic agents and disease progression found in alveolar proteinosis suggest that it represents one mechanism by which the lung responds to a variety of insults (Rosen, et al., 1958; Fishman, Pulmonary Diseases and Disorders, 2nd Edition, 1988, p. 893).

The material that fills the alveolar spaces in PAP is granular, protein-lipid in nature, and stains positive with the PAS stain. In most respects, the material in the alveoli is qualitatively similar to normal surfactant. Because of the excess of this material in the alveolar spaces, however, profound alterations occur in gas exchange and exercise tolerance, and it is also likely that its presence contributes to a marked decline in alveolar antimicrobial defenses. Surfactant is a substance formed in the lungs that helps to keep the small air sacs expanded by virtue of its ability to reduce the surface tension. Most evidence suggests that PAP is due to decreased removal of alveolar surfactant rather than to an increase in its production (Fishman, Pulmonary Diseases and Disorders, 1988).

There are several steps in the intraalveolar and intra-cellular regulation of the quantity of surfactant in the alveolar spaces. Interference with the cycle, particularly in the return phase, by diverse stimuli ranging from inorganic particulates, fibrogenic dusts, and wood products to viral infections could lead to a decrease in the uptake of the surfactant phospholipid from the alveolar spaces at the level of the surfactant apoproteins or the apoprotein-phospholipid product.

PAP has been associated with exposure to various occupational substances. Case reports have implicated coal, tin, and uranium, as well as cement, silica, bentonite, and alumina (Rosen Samuel H; Benjamin Castleman and Averill A. Liebow, "Pulmonary Alveolar Proteinosis," N Eng J Med, 258, 23;1123-1142, June, 1958; Rubin, Ava Gordon, L. Weisbrod and Douglas E. Sanders, "Pulmonary Alveolar Proteinosis: Relationship to Silicosis and Pulmonary Infection,' Radiology, 135:35-41, April 1980; Gough, I., "Correspondence concerning silicosis and alveolar proteinosis, Brit Med J. 1:629, March 1967; Davidson, Jean M. and W.M. Macleod, "Pulmonary Alveolar Proteinosis," Brit J Dis Chest, 63:13-28, 1969; Miller, Roberta R., Andrew M. Churg, Marion Hutcheon and Stephen Lam, "Pulmonary Alveolar Proteinosis and Aluminum Dust Exposure," Am Rev Resp Dis, 130:312–315, 1984). Most case reports characterize the dust exposures involved in these cases only as "heavy." However, one case study involving alumina (aluminum oxide dust) did characterize the dust obtained by lung biopsy as consisting of spheres less than 1 micron in diameter.

Rubin et al., 1980, report on the clinical course and treatment of 13 cases of pulmonary proteinosis seen at Toronto General Hospital from 1974 to 1978. The authors report that PAP appears to be a disorder of the alveolar lining cells that is characterized by an increase in the number of cells resembling granular Type II pneumocytes and inadequate clearance of pulmonary lipoproteins, and particularly of palmitoyl lecithin (surfactant). Treatment for the disease is palliative and consists of pulmonary lavage.

Davidson and Macleod reviewed the literature on PAP in 1969; these authors substantiate Rosen's original claim that PAP is primarily a disease of males [Davidson and Macleod, 1969, Pulmonary Alveolar Proteinosis, Brit J Dis Chest, 63, 13). The male-to-female ratio among reported cases is 3 to 1.

This ratio is most likely to be due to the fact that men rather than women generally work in dusty jobs. The authors also report that an analysis of the reported cases shows that nearly half of the affected individuals had been exposed to dusty environments or solvents.

Animal studies have demonstrated that PAP develops after exposure to a variety of mineral dusts and fumes. The condition has often been described in rats that have inhaled silica dust (Gross and de Treville, 1968; Heppleston et al., 1970, 1974; Heppleston, 1975).

Corrin and King (1970, Pathogenesis of experimental pulmonary alveolar proteinosis) exposed rats to pyro aluminum powder, pure quartz, quartz of 60% and 5% cristobalite content, or a non-fibrogenic feldspar. Alveolar proteinosis developed, in these animals and could be traced to the earliest stages of dust exposure. There was an increase in alveolar macrophages in all dust-exposed animals, especially in those who later developed proteinosis.

In the Muhle et al. study discussed earlier, lipoproteinaceous material was detected in the alveoli at the final sacrifice, predominantly in animals from the high toner and quartz exposure groups. A very slight to slight degree of lipoproteinosis was also seen in the high toner group animals, while lipoproteinosis of slight to moderate degree was observed in the quartz-exposed rats.

Researchers have concluded that there is an association between alveolar proteinosis and the development of fibrosis, although the nature of that relationship remains unclear. Hudson et al. (1974) suggest that the typical histological picture of PAP is an early stage of a disease in which the end stage is fibrosis (Hudson et al., Pulmonary Interstitial Fibrosis Following Alveolar Proteinosis, Chest, 65: June 6, 1974).

OSHA preliminarily concludes that there is ample evidence of dust overloading of the lung and pulmonary alveolar proteinosis to provide additional support for a total particulate PEL of 15 mg/m3 as an 8-hour TWA and a respirable dust PEL of 5 mg/m3, also as an 8-hour TWA, for all Particulates Not Otherwise Regulated. These limits are necessary to reduce the significant risk of dust overloading and PAP, as well as other dust-related effects such as physical irritation, reduced vision, etc. Consequently, OSHA is proposing to retain these limits in workplaces in construction and maritime and to propose them in agriculture. These limits cover both organic and inorganic PNORs. OSHA will continue to monitor

the research in these areas and may elect to revisit these issues in the future to determine whether these limits are adequately protective.

OSHA believes that good industrial hygiene practice requires that exposures to particulates be controlled in the workplace to or below the 15-mg/m3 level as an 8-hour TWA to protect workers in construction, maritime, and agriculture from the broad range of adverse effects associated with exposure to these substances. In the past, these particulates were often called "nuisance" or "inert" substances. These terms are misleading, however, because exposures to these substances in the workplace may cause serious and sometimes disabling effects. Further, good industrial hygiene and public health practice require that workplace exposures to particulates be maintained below the level associated with physical irritation, accidents, and respiratory effects.

PENTAERYTHRITOL
CAS: 115-77-5; Chemical Formula:
C(CH₂OH)₄
H.S. No. 1305

In construction and maritime, OSHA currently has no separate limit for pentaerythritol, although this substance is covered by an 8-hour TWA PEL of 15 mg/m3 TWA, the Agency's generic total particulate limit in these sectors. There is no PEL in agriculture. The ACGIH has a TLV®-TWA of 10 mg/m3 for pentaerythritol (total dust) containing less than 1 percent quartz. For construction, maritime, and agriculture, OSHA is proposing PELs of 10 mg/m3 TWA (total particulate) and 5 mg/m³ (respirable particulate) for this substance. These are the limits recently established for pentaerythritol in general industry.

Pentaerythritol is an odorless, white crystalline solid. It is used in making insecticides, lubricants, alkyd resins, explosives, tall oil esters, pharmaceuticals, and paint swelling agents (ACGIH 1986, p. 462). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Rats exposed to pentaerythritol at 11,000 mg/m³ for 6 hours showed no ill effects from a single exposure, and rats, dogs, and guinea pigs exposed 6 hours daily for 90 days also showed no effects (Keplinger and Kay 1964/Ex. 1–743). The oral LD50s in guinea pigs and mice were 11.3 and 22.5 g/kg, respectively; rats survived oral doses as high as 16 g/kg. At higher doses, animals displayed

diarrhea, tremors, ataxia, and loss of righting reflex (Keplinger and Kay 1964/ Ex. 1-743). Daily applications of a saturated aqueous solution of technical pentaerythritol to rabbit skin produced no significant irritation; a single application of 10 g/kg aqueous paste on intact or abraded rabbit skin produced no evidence of percutaneous absorption (Keplinger and Kay 1964/Ex. 1-743; Hercules, Inc., as cited in ACGIH 1986/ Ex. 1-3, p. 462). Instillation of a 50percent aqueous suspension into the conjunctival sac of rabbits' eyes resulted in slight transient irritation (Hercules, Inc., as cited in ACGIH 1986/ Ex. 1-3, p. 462).

Human volunteers are reported to have eliminated 85 percent of dietary pentaerythritol unchanged in the urine within 30 hours. A slight and transient increase in apparent blood sugar that was proportional to the ingested dose appeared in these subjects soon after administration (Berlow, Barth, and Snow 1958, as cited in ACGIH 1986/Ex.

1-3, p. 462).

In construction, maritime, and agriculture, OSHA is proposing 8-hour TWA PELs of 10 mg/m3 (total particulate) for pentaerythritol and 5 mg/m³ (respirable fraction). The Agency believes that these limits will protect employees in these sectors from the significant risks of physical irritation potentially associated with exposure to pentaerythritol at higher levels. OSHA believes that physical irritation constitutes a material impairment of health within the meaning of the Act. Promulgation of these limits will also make OSHA's PELs for this substance consistent across all regulated sectors.

CAS: None; Chemical Formula: None H.S. No. 1310

In construction, maritime, and general industry, OSHA covers perlite under its generic total particulate limit of 15 mg/m³. There is no PEL in agriculture. The ACGIH has a TLV*-TWA of 10 mg/m³ for perlite as total dust containing less than 1 percent quartz. OSHA is proposing TWA PELs of 15 mg/m³ for perlite as total particulate containing less than 1 percent quartz and 5 mg/m³ for perlite as the respirable fraction. These are the limits recently established for perlite in general industry.

Perlite is a natural volcanic glass; it is essentially an amorphous mineral consisting of fused sodium-potassium-aluminum silicate. Perlite has a wide variety of uses, which include use as an abrasive; in plaster and tile; in fertilizer; in concrete construction aggregates; as a filter aid, pipe insulator, soil conditioner, cleaner base, and insulation board filler;

in refractory products; and as tile mortar aggregate (Clayton and Clayton 1981, p. 3027; ACGIH 1986, p. 467).

Perlite is reported to have a free-silica content varying from zero to 3 percent (Anderson, Selvig, Baur et al. 1956 and the Perlite Institute, both as cited in ACGIH 1986/Ex. 1–3, p. 467). In its processed crude and expanded forms, perlite is reported to have a measurable quartz content of 0.4 percent quartz and 0.2 percent cristobalite (Sheckler 1977, as cited in ACGIH 1986/Ex. 1–3, p. 467). There are no published reports of adverse physiologic effects from exposure to perlite dust.

In construction, maritime, and agriculture, OSHA preliminarily finds that perlite is nontoxic when airborne total particulate concentrations are maintained at levels of 15 mg/m3 or below (as an 8-hour TWA) and when its quartz content is limited to a level below 1 percent crystalline silica. For these reasons, OSHA is proposing an 8hour TWA PEL of 15 mg/m3 for total perlite dust containing less than 1 percent quartz and a 8-hour TWA PEL of 5 mg/m3 for the respirable fraction in these sectors. OSHA preliminarily concludes that these limits will protect workers from the significant risk of eye, skin, and other forms of physical irritation associated with exposure to this substance. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

PICLORAM
CAS: 1918-02-1; Chemical Formula:
C₆H₃Cl₃N₂O₂
H.S. No. 1328

In construction and maritime, OSHA currently has no specific limit for picloram, although this substance has been covered by the Agency's generic total particulate limit of 15 mg/m3 (8hour TWA). There is no PEL in agriculture. The 1987-1988 ACCIH TLV®s for this substance are 10 mg/m3 as an 8-hour TWA and 20 mg as a 15minute STEL (both for total dust). In construction, maritime, and agriculture, OSHA is proposing a 10-mg/m3 8-hour TWA PEL for picloram (total dust) and a 5-mg/m3 8-hour TWA for the respirable fraction. These are the limits recently established in general industry.

Picloram is a white powder with an odor like that of chlorine. This substance is used as an herbicide and defoliant. It is used as a growth regulator on apricots, figs, and cherries and is used to control various weeds in the western states (ACGIH 1986, p. 489; HSDB 1986). When used in pesticidal applications and as directed on the label, this substance is regulated by the

EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Picloram has low acute oral toxicity. with LDso values of 3.75 g/kg for rats, 1.5 g/kg for mice, and 2.0 g/kg for rabbits (NIOSH 1979b, as cited in ACGIH 1986/ Ex. 1-3, p. 489). Two-year feeding studies revealed no ill effects in albino rats and beagle dogs from ingestion of doses up to and including 150 mg/kg/ day [McCollister and Leng 1969, as cited in ACGIH 1988/Ex. 1-3, p. 489). At 225 mg/kg/day, rats displayed moderate liver and kidney changes and, in females, slight body weight loss after 90 days. These authors [McCollister and Leng 1969, as cited in ACGIH 1986/Ex. 1-3, p. 489) also reported no fertility, reproduction, or lactation effects in albino rats fed at levels of up to 3000. ppm (0.3 percent) in a three-generational study. Although maternal toxicity in rats was reported at picloram dietary levels of 750 or 1000 mg/kg administered during days 6 through 15 of gestation, neither teratogenic nor neonatal effects were observed when subtoxic or maternally toxic doses of picloram were administered during organogenesis (Thomson et al. 1972, as cited in ACGIH 1986/Ex. 1-3, p. 489). The National Cancer Institute (NCI) (1977d) found a dose-related increase in benign liver tumors in female rats only and concluded that "under the conditions of the bioassay, the findings are suggestive of the ability of the compound to induce benign tumors in the livers of female Osborne-Mendel rats." Based on these results, NIOSH (Ex. 8-47, Table N4) concluded that "picloram is not a nuisance particulate and is not without toxic effects." OSHA notes that picloram must therefore be added to the list of substances formerly believed to be inert but subsequently shown to be toxic.

Based on this evidence, OSHA is proposing 8-hour TWA limits of 10 mg/ m3 (total particulate) and 5 mg/m3 (respirable fraction) for picloram in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that these total and respirable particulate limits will minimize the significant risk of material health impairment in the form of systemic effects, such as liver and kidney damage, that are potentially associated with exposure to this substance at higher levels. OSHA believes that these effects constitute material health impairments and that the proposed limits are necessary to substantially reduce these risks. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

PLASTER OF PARIS CAS: 7778-18-9; Chemical Formula: CaSO₄ H.S. No. 1331

In construction and maritime, OSHA's current 8-hour TWA exposure limit for Plaster of Paris is 15 mg/m3 (total particulate). The ACGIH has a 10-mg/ m3 TLV*-TWA for Plaster of Paris, measured as total dust. OSHA is retaining its current limit in construction and maritime and is proposing to extend this limit to agriculture, as well as the 5mg/m³ limit for the respirable fraction. These are the limits recently established for this substance in general industry.

Plaster of Paris is a fine, white powder used in wall plasters and wallboard, in the building industry for tiles and blocks, in moldings and statuary, and in the paper industry (Merck 1983, p. 234).

Where occupational exposures to Plaster of Paris have been limited, no toxic effects or organic diseases of the lungs have occurred. Exposure to excessive levels of dust in the workplace may result in reduced visibility or injury to the skin or mucous membranes from the dust itself, or in damage to the skin from the rigorous skin-cleansing procedures required to remove the dust (ACGIH 1986/Ex. 1-3).

In construction and maritime, OSHA is retaining both the 8-hour TWA of 15 mg/m³ (total particulate) and the 8-hour TWA PEL of 5 mg/m3 (respirable particulate) for Plaster of Paris and is proposing to extend these limits to agriculture. The Agency preliminarily concludes that these limits will protect workers in these industries from the significant risks of skin, eye, and other forms of physical irritation associated with exposure to this substance. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

PORTLAND CEMENT CAS: 65997-15-1; Chemical Formula: None H.S. No. 1333

In construction and maritime, OSHA currently has a limit of 50 mppcf (approximately 15 mg/m³) for Portland cement containing less than 1 percent crystalline silica. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 10 mg/m³ for Portland cement as total dust containing less than 1 percent quartz. OSHA is proposing PELs of 10 mg/m3, measured as total particulate, for Portland cement in the construction, maritime, and agriculture industries and of 5 mg/m3, measured as the respirable fraction. These are the limits recently established in general industry.

Portland cement refers to a class of cements that consist of odorless gray powders containing less than 1 percent crystalline silica. Portland cement is insoluble in water and contains tri-and dicalcium silicate, in addition to varying amounts of alumina, tricalcium aluminate, and iron oxide. Portland cement is used to manufacture mortar for building blocks, stone and pre-cast items and as a moisture sealant for the exterior of concrete blocks (NIOSH/ OSHA Occupational Health Guideline 1981, p. 3).

Intraperitoneal injection of Portland cement in guinea pigs produced an absorptive reaction, which is an effect typical of inert particulates. Portland cement is eventually eliminated from the tissue and is generally not considered harmful when ingested (Miller and Sayers 1941/Ex. 1-595).

In a study of industrial exposures, Gardner and associates (1939/Ex. 1-589) found no evidence of Portland-cementrelated pneumoconiosis in 2,278 workers who had been heavily exposed to this substance for prolonged periods of time (Gardner, Durkan, Brumfiel, and Sampson 1939/Ex. 1-589). Conflicting reports of pneumoconiosis (Parmeggiani 1951, as cited in ACGIH 1986/Ex. 1-3, p. 494; Prosperi and Barsi 1957/Ex. 1-1093) are attributed to the presence of silica in the inhaled dust rather than to exposure to Portland cement itself (ACGIH 1986/ Ex. 1-3, p. 494). Cement dermatitis does occur among exposed workers, however, as a consequence of the alkaline, abrasive, and hygroscopic properties of the wet cement, which cause irritation of the skin (Schwartz, Tulipan, and Birmingham 1957a/Ex. 1-1168).

In the construction, maritime, and agriculture industries, OSHA is proposing 8-hour TWA PELs of 10 mg/ m3 (total particulate) and 5 mg/m3 (respirable fraction) for Portland cement containing less than 1 percent quartz. The Agency preliminarily concludes that these limits will protect workers in these sectors against the significant risks associated with on-the-job exposures to Portland cement dust. These risks include eye, skin, and mucous membrane irritation, and may include more severe respiratory effects, all of which constitute material health impairments. Revising the total particulate limit to 10 mg/m3 as an 8hour TWA will also simplify employee exposure monitoring for Portland cement, since gravimetric rather than impinger methods can then be used. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

ROUGE CAS: None; Chemical Formula: None H.S. No. 1351

In construction and maritime, OSHA currently has no specific limit for rouge, although rouge is covered under the Agency's generic total particulate standard of 15 mg/m3 as an 8-hour TWA. There is no PEL in agriculture. The ACGIH has an 8-hour TLV®-TWA limit of 10 mg/m3 for rouge as total dust containing less than 1 percent quartz. OSHA is proposing 10 mg/m3 as the 8hour TWA PEL for the total particulate of rouge and 5 mg/m3 as the 8-hour TWA for the respirable fraction of rouge in construction, maritime, and agriculture. These are the limits recently established for these substances in general industry.

Rouge is a high-grade red pigment, composed mainly of ferric oxide, that is used as a polishing agent for glass. jewelry, etc., as an ingredient in pigments and magnetic tapes, and in metallurgy (ACGIH 1986, p. 325; Hawley's 1987, p. 1016).

There is evidence showing that exposure to hematite dust (ferric oxide) increases the risk of lung cancer in hematite miners, and this human evidence is consistent with the results of two recent animal studies: Warshawsky. Bingham, and Niemeier (1984), which showed that intratracheal administration of ferric oxide and exposure to benzo(a)pyrene (BaP) "enhances the metabolic activation of BaP"; and Niemeier, Mulligan, and Rowland (1986), which also found that ferric oxide has co-carcinogenic potential. In this rulemaking, OSHA's principal concern is to make the Agency's limits consistent across all regulated sectors; OSHA will consider rouge's carcinogenicity in the future in connection with the first PEL update rulemaking

Accordingly, OSHA is proposing an 8hour TWA PEL of 10 mg/m3 for the total particulate of rouge and an 8-hour TWA PEL of 5 mg/m3 for the respirable fraction in the construction, maritime, and agriculture industries. OSHA preliminarily concludes that these limits will protect workers in these sectors from the significant risks of physical irritation associated with workplace exposure to higher levels of rouge. These effects include eye, nose, and upper respiratory irritation and, perhaps, other more serious chronic diseases, all of which constitute material health impairments within the meaning of the Act. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all

regulated sectors.

SILICON CAS: 7440-21-3; Chemical Formula: Si H.S. No. 1359

In construction and maritime, OSHA currently has no specific limit for silicon; however, silicon is covered under OSHA's generic particulate limits of 15 mg/m³ TWA (total particulate) and 5 mg/m³ (respirable fraction). There is no limit in agriculture. The ACGIH has a 10-mg/m³ 8-hour TLV®-TWA for silicon, measured as total dust. In construction, maritime, and agriculture, OSHA is proposing a particulate PEL for silicon of 10 mg/m³ as an 8-hour TWA, as well as the 5-mg/m³ respirable fraction limit. These are the limits recently established for this substance in general industry.

Silicon is a black to gray, lustrous, needle-like crystal that is used in the manufacture of semiconductors, transistors, for making alloys such as ferrosilicon and silicon copper, and as a reducing agent in high-temperature reactions (ACGIH 1986, p. 526(86)).

The evidence of silicon's toxicity in animals is conflicting. An early study by McCord, Fredrick, and Stolz (1937/Ex. 1–640) reported no response in guinea pigs and rats injected intraperitoneally with silicon. A more recent study (Schepers 1971/Ex. 1–570) demonstrated pulmonary lesions in rabbits administered an intratracheal dose of 25

mg silicon dust.

OSHA is proposing an 8-hour TWA PEL of 10 mg/m3 (total particulate) and an 8-hour TWA PEL of 5 mg/m3 (respirable fraction) for silicon in the construction, maritime, and agriculture sectors. The Agency preliminarily concludes that these limits will reduce the significant health risks potentially associated with exposure to this substance at higher levels. These risks include eye, skin, mucous membrane and other forms of physical irritation and may include chronic respiratory effects. OSHA believes that these effects constitute material health impairments and that the proposed PELs will substantially reduce the risk of these health effects. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors. SILICON CARBIDE CAS: 409-21-2; Chemical Formula: SiC

H.S. No. 1360
In construction and maritime, OSHA currently covers silicon carbide under its generic 15-mg/m³ total particulate limit. There is no limit in agriculture.
The ACGIH TLV®-TWA is 10 mg/m³ over 8 hours, measured as total dust. In construction, maritime, and agriculture, OSHA is proposing an 8-hour TWA total particulate PEL for silicon carbide of 10

mg/m³ and an 8-hour TWA respirable fraction limit of 5 mg/m³. These are the limits recently established for this substance in general industry.

Silicon carbide is a green to blueblack iridescent crystal. It is used for polishing glass and granite, smoothing bisque ware, sharpening stones, and as an abrasive; it also finds use in the manufacture of porcelain, shoe soles, furnace linings, and antiskid pavements, and in semiconductor technology (Merck

1983, p. 1220).

An animal study (Gardner 1923/Ex. 1-737) showed that, although exposure to silicon carbide alone produced no fibrosis of the lungs, exposure of guinea pigs infected with tuberculosis to silicon carbide (six hours/day, five days/week for one year) aggravated pulmonary tuberculosis to the extent that extensive fibrosis occurred. Guinea pigs exposed to silicon carbide dust and infected with the tubercle bacteria developed tuberculopneumoconiotic lesions (Gross, Westrick, and McNerney 1959/Ex. 1-697). Miller and Sayers (1941/Ex. 1-595) observed that silicon carbide dust administered by intraperitoneal injection to guinea pigs produced no reaction.

Bruusgaard (1949/Ex. 1-1143) found that X-rays of 10 out of 32 workers exposed to average levels of 34 mppcf of silicon carbide for 15 years or more demonstrated pulmonary changes; these 10 workers were also tuberculinpositive. Miller, Davis, Goldman, and Wyatts (1953/Ex. 1-40) described three cases of pulmonary reactions and hyperglobinemia in tungsten carbide industry workers; these authors concluded that exposure to silicon carbide was not a hazard unless the exposed workers already had pulmonary tuberculosis. However, a recent case study (Hayashi and Kajita 1988) reports the case of a 36-year-old abrasives plant worker who developed cough and sputum and showed apical lesions on x-ray; the lesions were excised and were found to consist primarily of silicon carbide. The authors concluded that silicon carbide was responsible for this worker's pneumoconiosis. Another study Osterman, Greaves, Smith, Hammond, Robins, and Theriault 1989) has shown that workers in a silicon carbide factory with long-term exposure develop parenchymal changes leading to fibrosis.

In construction, maritime, and agriculture, OSHA is proposing a 10-mg/m³ TWA total particulate limit for silicon carbide and a 5-mg/m³ TWA respirable fraction limit. The Agency preliminarily concludes that these limits will protect workers in these sectors from the significant risk of material

health impairment in the form of physical irritation and, perhaps, of respiratory effects, that are associated with exposure to this particulate. These are the limits recently established for silicon carbide in general industry. STARCH

CAS: 9005-25-8; Chemical Formula: $(C_6H_{10}O_8)_n$

H.S. No. 1369

In construction and maritime, OSHA's limit for starch is 15 mg/m3 as an 8-hour TWA, the Agency's generic limit for all particulates. There is no PEL in agriculture. The ACGIH has a TLV®-TWA of 10 mg/m3 for starch as total dust that contains no asbestos and less than 1 percent crystalline silica. OSHA is retaining its current total dust and respirable fraction limits for starch in construction and maritime and is proposing to extend them to agriculture. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

Starch is a white, odorless powder. Starch has many uses, including use as an adhesive, textile filler and sizing agent, gelling agent, food product thickener, baking powder filler, fabric stiffener, indicator in analytical chemistry, anticaking agent, polymer base, and in face powders (Hawley's

1987, p. 1090).

Exposure to high concentrations of starch dust may result in impaired vision or may cause injury to the mucous membranes or skin. Injury may also result from the vigorous skincleansing procedures necessary for the complete removal of starch (ACGIH 1986/Ex. 1–3).

OSHA is retaining both the 8-hour TWA total particulate PEL of 15 mg/m³ and the 5-mg/m³ respirable particulate limit for starch in construction and maritime and is proposing these limits in agriculture. The Agency preliminarily concludes that these limits will reduce the significant risk of eye, skin, and other physical irritation that may result from exposure to high levels of starch in the workplace. In addition, promulgation of these limits will make OSHA's PELs for starch consistent across all regulated sectors.

SUCROSE CAS: 57-50-1; Chemical Formula:

C₁₂H₂₂O₁₁ H.S. No. 1374

In construction and maritime, OSHA's 8-hour TWA limit for sucrose is 15 mg/m³ as total particulate, the Agency's generic limit for all particulates. There is no limit in agriculture. The ACGIH includes sucrose among the group of

particulates that "do not produce significant organic disease or toxic effect when exposures are kept under reasonable control" (ACCIH 1986/Ex. 1-3) and has a TLV*-TWA limit of 10 mg/m³ for sucrose as total particulate containing no asbestos and less than 1 percent quartz. OSHA is retaining the 8-hour TWA PEL of 15 mg/m³ to*al particulate and the 8-hour TWA PEL 5 mg/m³ respirable fraction for sucrose in construction and maritime and is proposing these limits in agriculture. These are the limits recently established for sucrose in general industry.

Sucrose is found in the form of white crystals. It is used as a sweetening agent and food, as a starting material in fermentation, as a pharmaceutical preservative, and as an antioxidant, a demulcent, a glycerol substitute, a granulation agent, and an excipient for tablets (Merck 1983, p. 1273).

Exposure to excess levels of sucrose dust can cause skin and eye irritation, interference with vision, and distraction from the task at hand. The LD₅₀ in rats is 29, 700 mg/kg (RTECS 1991). Acutely poisoned animals showed prostration, diarrhea, cyanosis, convulsions, and stupor before death (HSDB 1991).

OSHA is retaining its 8-hour total particulate TWA of 15 mg/m³ and its 8-hour TWA respirable fraction limit of 5 mg/m³ for sucrose in construction and maritime and is proposing to extend these limits to agriculture. The Agency preliminarily concludes that these limits will protect exposed workers in these sectors from the significant risk of physical irritation associated with sucrose exposure. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

2.4.5-T (TRICHLOROPHENOXYACETIC

ACID)
CAS: 93-76-5; Chemical Formula:
C₈H₅C₁₃O
H.S. No. 2148

In general industry, construction, and maritime, OSHA's permissible exposure limit for 2,4,5-T is 10 mg/m³ as an 8-hour TWA. There is no limit in agriculture. The ACGIH has an 8-hour TLV*-TWA of 10 mg/m³ for 2,4,5-T. NIOSH has no REL for this substance but concurs (Ex. 8-47) with the limit being proposed. OSHA is proposing an 8-hour TWA limit of 10 mg/m³ for 2,4,5-T in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

2,4,5-T, which is 2,4,5trichlorophenoxyacetic acid, is an odorless, colorless to tan solid. This substance is a phenoxy acid herbicide that is used to control woody plants (ACGIH 1986, p. 549; NIOSH/OSHA Occupational Health Guideline 1981, p. 1). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

2,4,5-T causes irritation, chloracne, and systemic effects in humans and central nervous system and teratogenic effects in animals. In early studies of 2,4,5-T, dioxin was a common contaminant; the role of dioxin must therefore always be considered in evaluating early reports of 2,4,5-T's toxicity (Proctor, Hughes, and Fischman 1988, p. 490). The oral LD50 values in rats, mice, dogs, guinea pigs, and hamsters are 300 mg/kg, 242 mg/kg, 100 mg/kg, 381 mg/kg, and 425 mg/kg, respectively (RTECS 1991). The dermal LD50 in rats is 1535 mg/kg (RTECS 1991). A single oral 2,4,5-T dose of 100 mg/kg given to pigs caused signs of anorexia, vomiting, diarrhea, and ataxia; at autopsy, hemorrhagic enteritis and congestion of the liver and kidney were seen Björklund and Erne 1966, in IARC 1977, Vol. 15, p. 280). In groups of rats maintained on diets containing 2,4,5-T, changes were observed in male and female animals receiving 100 mg/kg; these changes included a reduction in weight gain, a decrease in food intake, elevated serum alkaline phosphatase levels, and, in males, increased serum glutamic-pyruvic transaminase levels (IARC 1977, Vol. 15, p. 281). Dogs fed daily doses of 20 mg/kg 2,4,5-T died 11 to 75 days after dosing began (Drill and Hiratzka 1953, in IARC 1977, Vol. 15, p. 282). A dose of 100 mg/kg given subcutaneously to pregnant mice on the 6th through the 15th days of gestation produced an increased incidence of cleft palate in the offspring (Moore and Courtney 1971, in Proctor, Hughes, and Fischman 1988, p. 490). In hamsters administered oral doses of 100 mg/kg/ day 2,4,5-T on days 6 to 10 of gestation, this substance caused signs of feticidal and teratogenic effects (Collins and Williams 1971, in Proctor, Hughes, and Fischman 1988, p. 490). A significant increase in the occurrence of cleft palate and embryotoxic effects was seen in mice after the oral administration of 35 to 130 mg/kg 2,4,5-T during days 6 to 15 of gestation (Roll 1971, in IARC 1977, Vol. 15, p. 285). Rats, rabbits, and monkeys appear to be relatively resistant to 2,4,5-T's teratogenic effects (Proctor, Hughes, and Fischman 1988, p.

The effects most frequently reported in workers exposed to 2,4,5-T include chloracne, liver disorders, neurological and behavioral changes, fat metabolism disorders, and porphyria cutanea tarda

(IARC 1977, Vol. 15, p. 288). However, the role of dioxin in the etiology of these disorders should not be overlooked. In 1964, an outbreak of chloracne affected 60 workers at a 2,4,5,-T factory of the Dow Chemical Company in Michigan (Firestone 1977, in IARC 1977, Vol. 15, p. 289). In 1969, employees of the same Michigan factory were reexamined and of 73 workers, 13 were found to have chloracne. Several of these workers had hyperpigmentation or facial hypertrichosis and one worker showed mild porphyrinuria. About 30 percent of these workers suffered from gastrointestinal symptoms such as nausea, vomiting, diarrhea, abdominal pain, and bloody stools; approximately 10 percent had symptoms including lower extremity weakness, headache, and decreased auditory acuity (Poland et al. 1971, in IARC 1977, Vol. 15, p. 289). In a factory in the USSR where 2,4,5-T was produced, 128 workers had skin lesions, and 69 of those examined had acne; many with severe lesions also suffered liver impairment. In 18 of these workers, a neurasthenic syndrome was observed (Telegina and Bikbulotova 1970, in IARC 1977, Vol. 15, p. 290). Among 228 people affected in an accident at a 2,4,5-T-producing factory in West Virginia, symptoms included chloracne, melanosis, muscular aches and pain, fatigue, nervousness, and cold intolerance (Firestone 1977, in IARC 1977, Vol. 15, p. 290). Eleven male volunteers showed no clinical effects after ingesting 5 mg/kg of 2,4.5-T: however, most did report having a metallic taste in the mouth which lasted 1 to 2 hours after ingestion (Gehring et al. 1973; Kohli et al. 1974a, in Hayes 1982, p. 530). A study of chemical application workers using 2,4,5-T in New Zealand revealed no significant differences in the rates of congenital defects, stillbirths, or miscarriages when compared with controls (Smith et al. 1981, in Proctor, Hughes, and Fischman 1988, p. 490). The International Agency for Research on Cancer has determined that the evidence for the carcinogenicity of 2,4,5-T in humans and animals is inadequate (IARC 1982, Suppl. 4, pp. 235-238).

Based on this evidence in humans and animals, OSHA preliminarily concludes that 2,4,5-T potentially causes irritation, neurological effects, and liver damage in exposed individuals. OSHA preliminarily finds that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that the proposed limit of 10 mg/m³ for 2,4,5-T in agriculture is necessary to significantly reduce these

risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for 2,4,5-T consistent across all regulated sectors.

TEMEPHOS

CAS: 3383-96-8; Chemical Formula: C₁₆H₂₀O₆P₂S₃

H.S. No. 1383

There is no specific limit for temephos in construction or maritime, although this substance is covered under OSHA's generic particulate limit of 15 mg/m3. There is no PEL in agriculture. The ACGIH limit is 10 mg/m3 (total dust) as an 8-hour TWA. In construction and maritime, OSHA is proposing an 8-hour TWA of 10 mg/m3 (total particulate) and is retaining the 5-mg/m3 limit for the respirable fraction of temephos dust; the Agency also proposes to extend both limits to agriculture. NIOSH (Ex. 8-47, Table N4) concurs with the selection of these PELs, which were recently established in general industry.

Temephos may be a white crystalline solid or a viscous brown liquid.

Temephos is used as an insecticide for the control of mosquito larvae, flies, and midges (Clayton and Clayton 1981, p. 4807; ACGIH 1986, p. 557). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide

Act (FIFRA).

In rats and mice, temephos has an acute oral LD50 of 400 mg/kg or greater. Various animal species tolerated doses of 10 mg/kg without clinical effect and 1 mg/kg without effect on cholinesterase activity (Gaines, Kimbrough, and Laws 1967/Ex. 1-553). Laws, Morales, Hayes, and Joseph (1967/Ex. 1-562) revealed that human volunteers consuming oral doses of temephos at levels of either 256 mg/person/day for five days or 64 mg/ person/day for four weeks evidenced no detectable effects on erythrocyte or plasma cholinesterase levels. Murphy and Cheever (1972/Ex. 1-567) reported that 1 mg of temephos per liter of drinking water produces no effect. These authors found that rat liver carboxylesterases were at least 30 times more sensitive to inhibition from temephos than were rat cholinesterases. Assuming that human liver carboxylesterases are proportionately more sensitive than cholinesterases, it is estimated that significant inhibition of these carboxylesterases could occur as a result of consuming 2 liters of drinking water containing 1 mg/L of temephos. Although nonspecific liver carboxylesterase is not critical for normal physiologic function, adverse effects on this enzyme could increase the susceptibility of exposed individuals

to chemicals and drugs that contain carboxylesterase linkages (ACGIH 1986/Ex. 1–3, p. 557).

OSHA is proposing an 8-hour TWA limit of 10 mg/m3 (total particulate) and 5 mg/m³ (respirable fraction) for temephos in construction, maritime, and agriculture. The Agency preliminarily concludes that these limits will protect workers in these sectors from the significant risk of cholinesterase inhibition and reduction in carboxylesterase activity, which together constitute material health impairments within the meaning of the Act and are potentially associated with exposure to this substance. In addition, promulgation of these limits will make OSHA's PELs for temephos consistent across all regulated sectors.

4,4'-THIOBIS (6-TERT-BUTYL-n-CRESOL)

CAS: 96-69-5; Chemical Formula: C₂₂H₃₀O₂S

H.S. No. 1391

In construction and maritime, OSHA is currently covering 4,4'-thiobis under the Agency's generic total particulate limit of 15 mg/m3 TWA. There is no PEL in agriculture. The ACGIH limit is 10 mg/m3 as an 8-hour TWA, the limit established by the ACGIH for all of the nuisance dusts. OSHA proposes a 10mg/m3 total particulate TWA limit and a 5-mg/m3 respirable fraction TWA PEL for 4,4'-thiobis in the construction, maritime, and agriculture industries, and NIOSH concurs (Ex. 8-47, Table N4) with the selection of these limits. These are the limits recently established for this substance in general industry.

4,4'-Thiobis is a light gray to tan powder with a slightly aromatic odor. This substance is an antioxidant for polyolefins, polyethylenes, and polypropylenes (ACGIH 1986, p. 570).

The intraperitoneal LD50 in mice is 50 mg/kg (RTECS 1991). The lethal oral dose in rats is approximately 5 g/kg (RTECS 1991). In a 30-day study, rats fed diets of 500 ppm 4,4'-thiobis exhibited normal weight gain; those rats fed five times this amount developed enlarged livers and had a reduced rate of weight gain (Lefaux 1968/Ex. 1-814). In a 90-day study reported by the same author, rats fed 50 ppm showed no toxic effects, but male rats fed 500 ppm ate and grew at a slightly lower rate. No pathologic changes were observed in the 500-ppm group. A dose of 5 g/kg of 4,4'-thiobis proved lethal to rats, with the predominant symptom being gastroenteritis.

In construction, maritime, and agriculture, OSHA is proposing exposure limits of 10 mg/m³ TWA (total particulate) and 5 mg/m³ TWA

(respirable fraction) for 4.4'-thiobis. The Agency preliminarily concludes that these limits will protect workers in these sectors from the significant risk of material health impairment, in the form of eye, skin, and other physical irritation, which is associated with exposure to this substance. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

TITANIUM DIOXIDE

CAS: 13463-67-7; Chemical Formula: TiO₂

H.S. No. 1396

In construction and maritime, OSHA's current PEL for titanium dioxide is 15 mg/m³ as an 8-hour TWA; this is the Agency's generic exposure limit for particulates. There is no PEL in agriculture. A 10-mg/m³ 8-hour TWA, measured as total dust, has been established by the ACGIH. The Agency is proposing 8-hour TWA PELs of 10 mg/m³ (total particulate) and 5 mg/m³ (respirable particulate) for titanium dioxide in construction, maritime, and agriculture; these are the limits recently established in general industry.

Titanium dioxide is a white crystalline solid. Titanium dioxide is used in paints paper, rubber, plastics, cosmetics, floor coverings, glassware and ceramics, printing inks, and welding rods (ACGIH 1986, p. 576; Hawley's 1987, p. 1159).

Miller and Sayers (1941/Ex. 1-595) reported that titanium dioxide injected intraperitoneally in guinea pigs remained in the tissues at the injection site but did not produce a proliferative response. A study by Grandjean, Turrian, and Nicod (1956/Ex. 1-638) in which rats were administered 50 mg of titanium dioxide intratracheally showed pigmented dust deposits in the lungs. In addition, evidence of infection appeared in the alveoli of one rat and diffuse fibrosis was found in the lungs of another test animal. No nodule formation was observed (Grandjean, Turrian, and Nicod 1956/Ex. 1-638). Another study by Dale (1973/Ex. 1-624) revealed thickening of the walls of the alveoli in the lungs of rabbits injected with titanium dioxide dust; however, the lungs of these animals had returned to normal by three months post-treatment. Feeding studies of rats and mice at doses of 2.5 percent or 5 percent titanium dioxide for 103 weeks revealed no signs of carcinogenicity in either species (National Cancer Institute 1979d/Ex. 1-947).

In the prior rulemaking, NIOSH (Tr. p. 3–95) testified that exposure to this substance is associated with "a risk of cancer. . . . The incidence of tumors in

animals exposed to titanium dioxide (Lee, Trochimowicz, and Reinhardt 1985) meets the . . . criteria for . . . [a] potential occupational carcinogen. Because OSHA's primary objective in the proposed rulemaking is to make the Agency's PELs for individual substances consistent across all regulated sectors, OSHA is proposing for construction, maritime, and agriculture the same limits as those recently established for titanium dioxide in general industry. In the first PEL update project, however, OSHA will evaluate the toxicologic literature on this substance to determine whether further reduction in the PEL is warranted in all sectors.

Accordingly, OSHA is proposing at this time 8-hour TWA PELs of 10 mg/m3 (total particulate) and 5 mg/m3 (respirable particulate) for titanium dioxide in the construction, maritime, and agriculture industries. OSHA preliminarily concludes that these limits will protect workers in these sectors from the significant health risks associated with exposure to titanium dioxide at higher levels. These risks include material impairments of health in the form of eye, skin, and other physical irritation, and, perhaps, of carcinogenicity. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors. VEGETABLE OIL MIST (EXCEPT

CASTOR OIL, CASHEW NUT, OR SIMILAR IRRITANT OILS) CAS: None; Formula: None H.S. No. 1423

OSHA has no limit for vegetable oil mist in construction, maritime, or agriculture. The ACGIH has established a 10-mg/m³ 8-hour TLV*-TWA for all nuisance particulates. OSHA is proposing a 10 mg/m³ 8-hour TWA PEL for total particulate and a 5 mg/m³ 8-hour TWA PEL for the respirable fraction in the construction, maritime, and agriculture sectors. NIOSH concurs (Ex. 8-47, Table N4) with the proposed limits. These are also the limits recently established in general industry.

Vegetable oil is a pale yellow, oily liquid. Vegetable oils are used in paints, shortenings, food products, rubber softeners, dietary supplements, and as pesticide carriers (Hawley's 1987, p.

Oil mist presents the same safety and health hazards as all of the physical irritants. Occupational exposure to vegetable oil mist is associated with interference with vision, eye tearing, and skin and other forms of physical irritation.

In construction, maritime, and agriculture, OSHA is proposing 8-hour

TWA limits of 15 mg/m³ (total particulate) and 5 mg/m³ (respirable particulate) for vegetable oil mist (except castor oil, cashew nut, or similar irritant oils). The Agency preliminarily concludes that these limits will protect workers in these sectors from the significant risks of physical irritation described above. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors. ZINC STEARATE

CAS: 557-05-1; Chemical Formula: Zn(C₁₅H₃₅O₂)₂ H.S. No. 1434

In construction and maritime, OSHA currently covers zinc stearate under its generic total particulate limit of 15 mg/m³ TWA. There is no PEL in agriculture. The ACGIH has established an 8-hour TWA of 10 mg/m³ for zinc stearate, measured as total dust. OSHA is proposing 8-hour TWA PELs of 10 mg/m³ (total dust) and 5 mg/m³ (respirable fraction) for zinc stearate in the construction, maritime, and agriculture industries. NIOSH concurred (Ex. 8-47, Table N4) that these PELs were appropriate when OSHA established them recently in general industry.

Zinc stearate is a white hydrophobic powder. Zinc stearate is used in cosmetics, lacquers, and ointments. It is also used as a dusting powder, lubricant, mold-release agent, filler, heat and light stabilizer, in the manufacture of tablets and dietary supplements (Hawley's 1987, p. 1257; ACGIH 1986, p.

A single intratracheal administration of 50 mg zinc stearate killed 50% of all exposed rats (Ueda et al. 1984). A report in Folia Medica (Volita and Noro 1957, as cited in ACGIH 1986/Ex. 1-3, p. 646) documented the case of a worker exposed to zinc stearate dust for 30 years who died from extensive fibrosis of the lungs. More recent studies have revealed incidences of pulmonary fibrosis associated with encephalopathy that stemmed directly from exposure to aluminum dust, which is frequently coated with stearic acid (British Journal of Industrial Medicine 1962, as cited in ACGIH 1986/Ex. 1-3, p. 646). Observations of long-term worker exposures to this dust in the rubber industry revealed no adverse effects of exposure (B.F. Goodrich Rubber Company, private communication, as cited in the ACGIH 1986/Ex. 1-3, p. 646).

In construction, maritime, and agriculture, OSHA is proposing a 10-mg/m³ TWA limit for zinc stearate (measured as total particulate) and a 5-mg/m³ TWA limit (measured as the respirable fraction). The Agency

preliminarily concludes that these limits will prevent the significant health risks associated with workplace exposures to zinc stearate dust at higher levels. OSHA believes that the pulmonary effects potentially associated with exposure to zinc stearate constitute material impairments of health within the meaning of the Act and that the proposed limits are necessary to reduce this risk. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

ZINC OXIDE DUST CAS: 1314–13–2; Chemical Formula: ZnO H.S. No. 1438

In construction, maritime, and agriculture, OSHA has no exposure limit specifically for zinc oxide dust. The ACGIH has a TLV*-TWA of 10 mg/m³ for zinc oxide, measured as total dust. In construction, maritime, and agriculture, OSHA is proposing an 8-hour TWA of 10 mg/m³ (measured as total particulate) and an 8-hour TWA of 5 mg/m³ (measured as the respirable fraction). These are the limits recently established in general industry.

Zinc oxide dust is a white or pale yellow powder. Zinc oxide is used as a pigment and reinforcing agent in rubber, and ointments, in plastics, ceramics, floor tile, glass, as a food additive, dietary supplement, and in seed treatment, cosmetics, copier machines, photography and paints (Hawley's 1987, p. 1255; Merck 1983, p. 1457).

In contact with the skin of rabbits, zinc oxide causes mild irritation; in the eyes, it also causes a mild reaction (RTECS 1991). The LD50 in mice is 7950 mg/kg (RTECS 1991). According to Turner and Thompson (1926/Ex. 1-1124). exposure to finely divided zinc oxide dust can produce symptoms similar to those of metal fume fever. Beeckmans and Brown (1963/Ex. 1-775) reported that catalytically active zinc oxide dust is more toxic when treated with ultraviolet light. Metal fume fever, the principal health effect of zinc oxide exposure, causes chills, fever, dry cough, and substernal pain (Rohrs 1957). Leukocytosis occurs in severe attacks (McCord 1960). Several recent studies suggest that exposure to zinc oxide dust causes respiratory effects (Gupta, Pandey, Misra, and Viswanathan 1986; Lam, Conner, Rogers et al. 1985; and NIOSH 1975d). The PEL for zinc oxide may have to be reduced further if toxicological review at the time of OSHA's first PEL update indicates that further reduction is warranted.

In construction, maritime, and agriculture, OSHA is proposing limits of

10 mg/m³ TWA (total particulate) and 5 mg/m³ TWA (respirable particulate) for zinc oxide. The Agency preliminarily concludes that these limits will protect workers in these sectors from the significant risk of material health impairment in the form of physical irritation and, perhaps, of respiratory effects. The Agency believes that the proposed PELs are necessary to reduce these risks. In addition, promulgation of these limits will make OSHA's PELs for zinc oxide consistent across all regulated sectors.

Preliminary Conclusions

OSHA's current generic 8-hour TWA particulate standard (29 CFR 1910.1000, Table Z-3) in construction and maritime was adopted from the 1970 ACGIH TLV*-TWA of 15 mg/m3 for total dust and 5 mg/m3 for respirable dust. At the time, the ACGIH considered the 15-mg/ m3 value to be "an acceptable limit of good hygienic practice," based on the then-prevailing "lack of knowledge" of any adverse exposure-related effects at levels below this value (Documentation of the Threshold Limit Values and Biological Exposure Indices, ACCIH 1966/Ex. 1-13). Shortly after OSHA adopted the ACGIH's 1970 limit, the ACCIH revised its limit downward to 10 mg/m3 for total dust and 5 mg/m3 for respirable dust. In justifying this reduction, the ACGIH noted that the lower levels would "result in appreciable improvement of working conditions in plants where the old limit

of 15 mg/m³ formerly prevailed"
[Documentation of the Threshold Limit Values for Substances in Workroom Air, 3rd ed., p. 190, ACGIH 1971).

In this proposed rule, OSHA has preliminarily determined that it is appropriate to set a 10-mg/m3 total particulate limit and to retain the 5-mg/ m3 respirable fraction limit for those particulates demonstrated to have, in addition to physical-irritant properties, specific adverse health effects. This is the policy OSHA followed in the recent air contaminants rulemaking for general industry. These substances will also be identified separately in Tables Z, Construction; Z, Shipyards; Z, Longshoring & Marine Terminals; and Z. Agriculture. For the substances in this section that are physical irritants but for which other health effects have not specifically been identified, OSHA is retaining the 8-hour TWA total particulate limit of 15 mg/m3 and the 8hour TWA respirable fraction limit of 5 mg/m3 in construction and maritime and is proposing to extend these limits to agriculture. For those particulates not otherwise regulated, which includes all workplace particulates, both organic and inorganic that are not separately identified on Tables Z, Construction; Z, Shipyards; Z. Longshoring & Marine Terminals; and Z, Agriculture, OSHA is proposing a generic total particulate limit of 15 mg/m3. For all particulates, OSHA is retaining the 5-mg/m3 TWA limit for the respirable fraction in construction and maritime and is

proposing this limit in agriculture. Promulgation of these limits will make OSHA's PELs for these substances consistent across all regulated sectors.

11. Substances for Which Proposed Limits Are Based on Analogy to Related Substances

Introduction

OSHA is proposing limits for 96 substances on the basis of their toxicologic and structural similarities to other chemical substances that create significant risks of systemic toxicity. ocular effects, kidney or liver damage. and other similarly adverse health effects. For many of these substances, OSHA has not previously had permissible exposure limits (PELs) in construction and maritime; for others, limits are currently in place in these sectors. The Agency has no PELs for any of these substances in agriculture. OSHA is proposing to establish PELs in construction, maritime, and agriculture that are identical to their limits in general industry. Promulgation of these PELs would thus make OSHA's limits for these substances consistent across all OSHA-regulated sectors.

Table C11–1 shows these substances, their CAS and HS numbers, and their 1987–1988 ACGIH TLV*s and NIOSH RELs. The table also shows the current limits for these substances in construction and maritime and the limits OSHA is proposing for them in construction, maritime, and agriculture.

*OSHA's PELs do not currently apply in Agriculture; OSHA's TWA limits are for 8-hour exposures; its STELs are for 15 minutes unless otherwise specified; and its ceilings are peaks not to be exceeded for any period of time.

**The ACGIH TLV*-TWA is for an 8-hour exposure; its STELs are 15-minute limits not to be exceeded more than 4 times per day with a minimum of 60 minutes between successive STEL exposures; and its ceilings are peaks not to be exceeded for any period of time. An A2 designation means that the ACGIH has designated the substance a suspected human carcinogen.

*NIOSH TWA limits are for 10 hour/day, 40 hour/week exposures unless otherwise specified, and its ceilings are peaks not to be exceeded for any period of time unless a duration is specified in parentheses.

*1888 NIOSH considers this substance a potential occupational carcinogen and recommends that exposures be reduced to the lowest feasible concentration.

Description of the Health Effects

The health effects associated with occupational exposures to the diverse group of substances shown in Table C11-1 vary widely, ranging from sensory irritation, systemic toxicity, ocular effects, and neuropathy to renal and

liver damage. This variation in target organs reflects the fact that the substances in this group have not been grouped on the basis of similarity in toxic effects, target organs, or mechanism of action; instead, they are considered together because the specific limits being proposed for them have

been set on the basis of toxic effects observed after exposure to analogous chemicals. Table C11-2 shows these substances, along with their adverse health effects and the substances with which they share structural and toxicological similarities.

TABLE C11-2.—SUMMARY OF RATIONALE FOR PROPOSED LIMITS BASED ON ANALOGY TO RELATED SUBSTANCES

	H.S. No./chemical name	Substance with analogous structure or activity	Associated health effects
1003	Acetic anhydride	Acetic acid	Sensory irritation.
1009	Acrylic acid		Sensory irritation.
1015	Aluminum (alkyls)		
1018	Aluminum (soluble salts)	Hydrogen chloride	Sensory irritation.
2006	sec-Amyl acetate	Amyl acetates	Sensory irritation.
1040	Boron tribromide		
1043	Bromine pentafluoride		
2022	sec-Butyl acetate		
2023	tert-Butyl acetate		
1048	Butyl acrylate		
1055	o-sec-Butylphenol		
1059	Calcium hydroxide		
1060	Calcium oxide		
1074	Carbonyl fluoride		Sensory irritation.
1075	Catechol	Phenol	Peripheral vaso-constriction, renal tubule dege eration.

TABLE C11-2.—SUMMARY OF RATIONALE FOR PROPOSED LIMITS BASED ON ANALOGY TO RELATED SUBSTANCES—Continued

	H.S. No./chemical name	Substance with analogous structure or activity	Associated health effects
0.4	1-Chloro-1-nitropropane	Nitropropane	Damage to heart muscle, liver, and kidneys.
81	Cobalt carbonyl	Nickel carbonyl	
98	Cobalt hydrocarbonyl	Nickel carbonyl	
12	Cresol (all isomers)	Phenol	
	Crotonaldehyde	Acrolein	
43	Demeton	Parathion	
19	Diazinon	Parathion	
18	1,1-Dichloro-1-nitroethane	Related compounds	Systemic toxicity.
21	p-Dichlorobenzene	o-Dichlorobenzene

The use of structural analogy is a reasonable methodology for limit-setting because of the similarities in structure and activity between each substance in this group and at least one other toxic substance. Industrial hygienists and toxicologists frequently use this approach when dealing with lesser known substances either in the workplace or the laboratory. The limits for the substances in this group are being proposed based on dose-response information for other compounds that have a similar chemical structure or are known to have a similar mechanism of action. For example, limits are being proposed for a number of substances that are known cholinesterase inhibitors (including diazinon, disulfoton, and monocrotophos); however, since direct dose-response data are not available for these substances specifically, OSHA has proposed limits that are similar to the proposed limit for parathion, another cholinesterase inhibitor for which adequate dose-response data are available.

It is important to note that the setting of a limit on the basis of analogy to other substances does not mean that no information is available to demonstrate that the substance is toxic: acute animal data are available to demonstrate the toxicity of all of the substances for which limits are being proposed in this category, and, for several substances, there are case reports of human poisonings caused by exposure. Thus, the limits being proposed for these substances reflect much more than a theoretical consideration of chemical structure and physiologic reaction: the hazardous nature of exposure to every substance in this category has been demonstrated beyond doubt, although the precise level at which these effects will occur has not been established with certainty.

The following sections describe
OSHA's preliminary findings for the
substances in this group. They also
discuss the material health impairments
likely to occur among workers in
construction, maritime, and agriculture
as a consequence of occupational
exposure to these substances.

ACETIC ANHYDRIDE

CAS: 108-24-7; Chemical Formula:
(CH₃CO)₂O

H.S. No. 1003

The OSHA PEL for acetic anhydride in construction and maritime operations is 5 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV* of 5 ppm as a ceiling, based on analogy with acetic acid's (TLV=5 ppm ceiling) irritant potential. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. In construction, maritime, and agriculture, OSHA is proposing a 5 ppm ceiling for acetic anhydride. This is the limit recently established for this substance in general industry.

Acetic anhydride is a colorless, mobile, strongly refractive liquid with a strong odor. Acetic anhydride is used in the manufacture of plastics and cellulose acetate fibers, in the synthesis of vinyl acetate, and as a dehydrating and acetylating agent in the production of insecticides, pharmaceuticals, dyes, explosives, perfumes, and aspirin (ACGIH 1986, p. 5).

In one study, rats inhaling 1000 ppm of acetic anhydride for 4 hours survived. but 2000 ppm was fatal (Smyth 1956/Ex. 1-759). In human studies, eye, nose, and throat irritation has been observed, and it has been suggested that bronchial and lung injury may occur as a consequence of exposure (Henderson and Haggard 1943j, as cited in ACGIH 1986/Ex. 1-3, p. 5). Skin burns and serious corneal injury have been reported in industrial settings when workers came into contact with the liquid (McLaughlin 1946/Ex. 1-641). and acetic anhydride is a marked lacrimator (Fairhall 1949b, as cited in ACGIH 1986/Ex. 1-3, p. 5).

In light of acetic anhydride's potential for acute toxicity, OSHA is proposing a 5-ppm ceiling limit in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors from the significant risk of ocular and respiratory effects associated with high, short-term exposures to acetic anhydride. OSHA believes that ocular and respiratory effects constitute material impairments of health. The proposed limit will substantially reduce these risks among workers exposed to this substance in these sectors. In

addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

ACRYLIC ACID
CAS: 79-10-7; Chemical Formula:
CH₂=CHCO₂H
H.S. No. 1009

OSHA has no permissible exposure limit for acrylic acid in construction, maritime, or agriculture operations. The ACGIH has an 8-hour TLV*-TWA of 10 ppm. NIOSH has no REL. OSHA is proposing an 8-hour TWA of 10 ppm. with a skin notation, for acrylic acid in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry.

Acrylic acid is a colorless, corrosive liquid with a distinctive acrid odor. Acrylic acid is known to polymerize explosively with amines, ammonia, oleum, and chlorosulfonic acid, and it is incompatible with strong alkalis and pure nitrogen. Occupational exposure to acrylic acid usually occurs when the chemical is used in the form of methyl, ethyl, or butyl esters in the manufacture of acrylic resins. It is also used in coatings, paints, adhesives, polishes, general finishes, and in binders (ACGIH 1986, p. 14.1(87)).

Data indicate that the oral LD₅₀ in rats is between 0.25 and 0.5 mg/kg (Dow Chemical Company 1977f, as cited in ACGIH 1986/Ex. 1–3, p. 14), and the skin absorption LD₅₀ in rabbits is 0.95 ml/kg (Smyth, Carpenter, Weil et al. 1962/Ex. 1–441). Another study indicates that rabbits given acrylic acid orally showed no ill effects at a level of 0.025 mg/kg (Klimkina et al. 1969, as cited in ACGIH 1986/Ex. 1–3, p. 14), and Gage (1970/Ex. 1–318) reports that rats exposed to 80 ppm for 6 hours daily for 20 days showed no adverse effects.

Case reports indicate that acute exposures to acrylic acid in workers have caused skin burns, eye burns, and upper respiratory tract effects (ACGIH 1986/Ex. 1–3, p. 14). NIOSH (Ex. 8–47, Table N2) believes that the PEL for acrylic acid should be lower than the limit being proposed, based on recent studies demonstrating degeneration of the nasal mucosa, changes in pulmonary function, and skin absorption in animals exposed to this substance (Miller, Ayres, Jersey, and Mckenna 1981 and Silver.

Leith, and Murphy 1981, both as cited in ACCIH 1986/Ex. 1-3, p 14.1). OSHA is aware of the recent literature on acrylic acid; however, the primary objective of this rulemaking is to make the Agency's limits consistent across sectors. In a future PEL update rulemaking, OSHA will evaluate the evidence for acrylic acid to determine whether a reduction in the PEL is warranted.

At the present time, however, OSHA preliminarily concludes that an 8-hour TWA PEL of 10 ppm and a skin notation are necessary to protect workers in construction, maritime, and agriculture from the significant risk of nasal and eye irritation, both material health impairments that are potentially associated with exposure to acrylic acid. The Agency believes that this limit will substantially reduce this risk and prevent recurrences of the burns and irritation previously associated with occupational exposures to acrylic acid. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

ALUMINUM (ALKYLS) CAS: 7429-90-5 Chemical Formula: Al H.S. No. 1015 ALUMINUM (SOLUBLE SALTS) CAS: 7429-90-5 Chemical Formula: Al H.S. No. 1018

OSHA has no permissible exposure limits in construction, maritime, or agriculture for either the soluble salts of aluminum or the aluminum alkyls. The ACGIH has an 8-hour TLV®-TWA limit of 2 mg/m3 for aluminum (soluble salts) and of 2 mg/m³ for the aluminum alkyls. There is no NIOSH REL, but NIOSH concurs (Ex. 8-47, Table N1) that the limits being proposed are appropriate. OSHA is proposing a 2 mg/m3 8-hour TWA PEL for the aluminum alkyls and the soluble salts of aluminum in construction, maritime, and agricultural operations. This is the limit recently established for these substances in general industry.

Aluminum in its elemental form is a white, malleable, ductile metal (ACGIH 1986, p. 22). Aluminum alkyls are organic compounds containing aluminum; the decomposition products of the alkyls (such as aluminum trioxide) are mucous membrane and pulmonary irritants. The soluble salts (e.g., aluminum sulfate, aluminum trichloride) form hydrolyzed acid in contact with

OSHA's limits for the aluminum soluble salts were set for general industry workplaces on the basis of the amount of hydrolyzed acid, such as

hydrochloric acid or sulphuric acid, in their acid compounds. For example, three mols of hydrogen chloride (HCl) hydrolize from one mol of aluminum chloride; since HCl has a PEL of 5 ppm, a PEL of 2 mg/m3 for aluminum chloride (which is a soluble salt of aluminum) would provide the same degree of protection from irritation as that provided by OSHA's limit for HCl. The acute toxicity of aluminum chloride is generally representative of the toxicity of all of the soluble salts of aluminum. For the aluminum alkyls, toxicity data are sparse. However, all of the nonhalogenated alkyls decompose into aluminum oxide fume, and the halogenated alkyls are even more irritating because of acid hydrolysis.

OSHA is proposing an 8-hour TWA limit of 2 mg/m3, for both the soluble salts of aluminum and the aluminum alkyls, in construction, maritime, and agriculture. The Agency preliminarily concludes that these limits will protect workers in these sectors against the significant risk of irritation and skin burns, which constitute material health impairments that are associated with exposure to these substances. In addition, promulgation of these limits will make OSHA's PEL for these substances consistent across all regulated sectors.

sec-AMYL ACETATE CAS: 628-63-7; Chemical Formula: CH3COOCH(CH3)C3H7 H.S. No. 2006

In general industry, construction, and maritime, OSHA's permissible exposure limit for sec-amyl acetate is 125 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV® of 125 ppm (665 mg/m3) as an 8-hour TWA for this substance; NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 125 ppm for sec-amyl acetate in agriculture. This is the limit recently established for this substance in general industry.

sec-Amyl acetate is a colorless, volatile liquid with a mild, non-residual, fruity odor. This substance is used as a solvent for nitrocellulose and ethyl cellulose cements, coated papers, lacquers, leather finishes, nail enamels, plastic wood, textile sizing, printing compounds, washable wallpaper, and chlorinated rubber. sec-Amyl acetate also finds use in metallic paints. perfumes, and pearlescent coatings for artificial pearls (ACGIH 1986, p. 29; Hawley's 1987, p. 75; HSDB 1989).

sec-Amyl acetate is an irritant of the eyes, skin, and respiratory tract; at high concentrations, it causes narcosis. The lowest lethal concentration in guinea

pigs is 10,000 ppm for 5 hours (RTECS 1990). Much of the toxicological literature does not distinguish between the isomers of amyl acetate; however, all of the industrially important amyl acetate isomers have similar toxicological effects (AIHA 1978; Pagnotto 1964). Guinea pigs exposed to a 10,000-ppm concentration of sec-amyl acetate for 5 hours showed signs of eye and nose irritation, became narcotized, and died (Clayton and Clayton 1981, p. 2274). When the concentration was lowered to 5000 ppm for 13 hours, guinea pigs developed the same signs and symptoms but subsequently recovered (Clayton and Clayton 1981, p. 2274).

Humans exposed to a 5000- to 10,000ppm concentration of sec-amyl acetate for short periods of time (not further specified) experienced irritation of the eyes and nasal passages (van Oettingen, 1960); however, exposure to a 1000-ppm concentration for 1 hour caused toxic effects described as "serious" (Amor 1950). A 200-ppm concentration of secamyl acetate is reported to have caused eye, nose, and upper respiratory tract irritation in one individual exposed for an unspecified amount of time (RTECS

Based on this evidence in humans and animals, and by analogy to effects caused by exposure to n-amyl acetate, OSHA is proposing to establish an 8hour TWA PEL for sec-amyl acetate of 125 ppm in agriculture; adoption of this limit would establish the same PEL for workplaces in all OSHA-regulated industry sectors. The Agency preliminarily concludes that occupational exposure to sec-amyl acetate causes irritation of the eyes and respiratory tract, and, at high concentrations, narcosis. Accordingly. OSHA believes that, in the absence of a permissible exposure limit, workers in agriculture are potentially at significant risk of these exposure-related effects and that the proposed PEL will substantially reduce these risks.

BORON TRIBROMIDE CAS: 10294-33-4; Chemical Formu.a: BBra H.S. No. 1040

In construction and maritime, OSHA has a limit of 1 ppm as an 8-hour TWA for boron tribromide. There is no limit in agriculture. The ACGIH has a 1-ppm TLV*-ceiling limit for boron tribromide. NIOSH has no REL for this substance. The proposed PEL in construction, maritime, and agriculture, with which NIOSH concurs (Ex. 8-47, Table N1), is a ceiling of 1 ppm. This is the limit recently established for boron tribromide in general industry.

Boron tribromide is a colorless, fuming liquid used primarily in the manufacture of diborane and high-purity

boron (ACGIH 1986, p. 62).

Boron tribromide has a high potential for acute local irritation, and its potential for systemic toxicity is analogous with that of hydrogen bromide (HBr). On decomposition, one molecule of boron tribromide would be expected to produce three molecules of HBr (ACGIH 1986/Ex. 1-3, p. 62). Animals repeatedly exposed to boron tribromide develop pneumonia, and exposure to 100 ppm caused a uniformly high mortality rate in animals of six laboratory species (Stokinger, Spiegel et al. 1953, as cited in ACGIH 1986/Ex. 1-3, p. 63). Rats, rabbits, and mice exposed to 1.5, 3.4, or 12.8 ppm boron trifluoride developed pneumonitis and dental fluorosis, although the evidence of pneumonitis was described as "marginal" at the lowest level tested (Torkelson, Sadek, and Rowe 1961, as cited in ACGIH 1986/Ex. 1-3, p. 63).

Based on this evidence of boron tribromide's severe pulmonary toxicity at exposure levels of 3.4 ppm, OSHA is proposing a ceiling limit of 1 ppm for this substance in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors from the significant risk of serious pulmonary damage, a material health impairment that is associated with exposure to this substance at levels above the proposed PEL. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. BROMINE PENTAFLUORIDE CAS: 7789-30-2; Chemical Formula: BrF5 H.S. No. 1043

In construction and maritime, OSHA's limit for bromine pentafluoride is 0.1 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 0.1 ppm for this substance. NIOSH has no REL, but concurs (Ex. 8-47, Table N1) with the proposed limit. OSHA is proposing an 8-hour TWA of 0.1 ppm for this substance in agriculture. This is the limit recently established for this substance in general industry.

Bromine pentafluoride is a highly reactive pale yellow liquid at temperatures below 40.3 °C; above this temperature, it is a colorless, pungent, corrosive gas. It is used in organic synthesis and as an oxidizer in liquid rocket propellants (Hawley's 1987, p.

Bromine pentafluoride has been shown to be acutely toxic in animals. Animals exposed to bromine

170).

pentafluoride vapor at 500 ppm exhibited immediate symptoms of gasping, swollen eyelids, clouded corneas, tearing, salivation, and acute distress; these symptoms appeared after exposure for a period as short as three minutes. Exposures to 50 ppm were fatal after 30 minutes, and chronic exposures above 3 ppm resulted in severe nephrosis (in some animals), as well as marked hepatosis and severe respiratory involvement (The Matheson Co., Inc., as cited in ACGIH 1986/Ex. 1-3, p. 66). Bromine pentafluoride is toxicologically more active than free, elemental fluorine, and its toxicity appears to be closely related to that of chlorine trifluoride (Horn and Weir 1955/Ex. 1-592; Horn and Weir 1956, as cited in ACGIH 1986/Ex. 1-3, p. 66). Chlorine trifluoride has caused severe toxicity and some fatalities in dogs and rats exposed over a period of 8 months to an average concentration of 1.17 ppm for 6 hours daily (Horn and Weir 1955/ Ex. 1-592).

OSHA is proposing a PEL of 0.1 ppm as an 8-hour TWA for bromine pentafluoride in agriculture to prevent the significant risk of serious systemic injury potentially associated with exposure to this substance at levels above the proposed limit. The Agency preliminarily concludes that this limit will substantially reduce this risk of systemic toxicity, which constitutes a material impairment of health, among agricultural workers. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. sec-BUTYL ACETATE CAS: 105-46-4; Chemical Formula:

CH₃COOCH(CH₃)CH₂CH₃ H.S. No. 2022

OSHA's PEL for sec-butyl acetate in general industry, construction, and maritime is 200 ppm as an 8-hour TWA; there is no PEL in agriculture. The ACGIH TLV*-TWA for sec-butyl acetate is 200 ppm as an 8-hour TWA. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 200 ppm for sec-butyl acetate in agriculture. This is the limit recently established for this substance

in general industry.
sec-Butyl acetate is a colorless liquid
with the fruity odor that is characteristic
of acetates (ACGIH 1986, p. 73). secButyl acetate is widely used as a
solvent; some materials that contain this
substance are thinners, nitrocellulose
lacquers, nail enamels, and leather

finishes (HSDB 1990).

In both humans and animals, secbutyl acetate causes irritation of the

eyes, mucous membranes, and respiratory tract; at high concentrations, it is believed to cause narcosis (ACGIH 1986, p. 73; Proctor, Hughes, and Fischman 1988, p. 105). By analogy with the effects of exposure to other acetates, overexposure to sec-butyl acetate causes the gradual onset of narcosis; the oral administration of acetates (form and dose not specified) caused a progressive loss of coordination in rabbits (Clayton and Clayton 1981, pp. 2268-2269). The vapor of sec-butyl acetate is reported to be less irritating to humans than the vapor of n-butyl acetate (ACGIH 1986, p. 73). Repeated contact of the skin with this substance causes irritation and dermatitis; possible allergic reactions have also been reported (Genium MSDS 1983, No. 519; New Jersey Fact Sheet 1985, p. 2).

Based on this evidence, OSHA preliminarily concludes that agricultural workers exposed to this substance at the levels permitted by the absence of a limit are at significant risk of experiencing irritation of the eyes, skin, mucous membranes, and upper respiratory tract. At very high concentrations, they may also be at risk of experiencing narcotic effects. The Agency believes that establishing a PEL of 200 ppm as an 8-hour TWA will protect workers in agriculture from these significant risks, which OSHA considers material health impairments. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

tert-BUTYL ACETATE
CAS: 540-88-5; Chemical Formula:
CH₃COOC(CH₃)₃
H.S. No. 2023

In general industry, construction, and maritime, OSHA's permissible exposure limit for tert-butyl acetate is 200 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 200 ppm for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL in agriculture of 200 ppm for tert-butyl acetate. This is the limit recently established for this substance in general industry.

The principal use for tert-butyl acetate is as a gasoline additive; however, this substance is also used as a solvent (HSDB 1986), tert-Butyl acetate is a colorless liquid with a fruity, acetate-like odor (ACGIH 1986, p. 74).

tert-Butyl acetate is an irritant of the eyes, mucous membranes, and upper respiratory tract in both animals and humans; at high concentrations, this substance is believed to be a depressant

of the central nervous system (Proctor, Hughes, and Fischman 1988, p. 105; ACGIH 1986, p. 74). The vapors of tertbutyl acetate are reported to be less irritating to the throat than those of nbutyl acetate (ACGIH 1986, p. 74). The administration of excessive (dose not further specified) quantities of acetates initially causes eye, throat, and nose irritation, followed by the gradual onset of narcosis; these effects reverse when exposure ceases (Clayton and Clayton 1981, p. 2268). Human subjects exposed for 2 to 3 hours to butyl acetate concentrations (isomer not specified) of 400 to 600 ppm did not experience symptoms of narcosis, although eye irritation was experienced at a 200- to 300-ppm concentration (Clayton and Clayton 1981, p. 2271).

Based on this evidence, OSHA preliminarily concludes that, in the absence of a permissible exposure limit, workers in agriculture are at significant risk of experiencing the eye, nose, and throat irritation associated with exposure to tert-butyl acetate and that they may also be at significant risk of experiencing central nervous system depression. The Agency believes that establishing an 8-hour TWA PEL of 200 ppm will substantially reduce this risk. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

BUTYL ACRYLATE
CAS: 141-32-2; Chemical Formula:
H₂C=CHCO₂(CH₂)₃CH₃
H.S. No. 1048

In construction, maritime, and agriculture, OSHA has no limit for butyl acrylate. The ACGIH's TLV*-TWA is 10-ppm. NIOSH has no REL. The proposed PEL, with which NIOSH concurs (Ex. 8-47, Table N1), is 10 ppm as an 8-hour TWA; this limit would apply in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry.

Butyl acrylate is a colorless, flammable liquid. Butyl acrylate is used in the manufacture of polymers and resins and is also used in paint formulations (ACGIH 1986, p. 75).

Butyl acrylate is a skin and eye irritant and is toxic to animals. The LC₅₀ for a 4-hour exposure is 1000 ppm (Carpenter, Weil, and Smith 1974/Ex. 1–304). In rabbits, the dermal LD₅₀ for butyl acrylate is approximately 1800 mg/kg, compared with 1235 mg/kg for methyl acrylate (Smyth, Carpenter, and Weil 1951/Ex. 1–439). Butyl acrylate has also been found to be mildly irritating to the skin and to produce corneal necrosis in the unwashed eyes of rabbits

(Holland 1974, as cited in ACGIH 1986/ Ex. 1-3, p. 75).

OSHA is proposing an 8-hour TWA PEL of 10 ppm for butyl acrylate, based on the similarity of the toxicological response of butyl acrylate to methyl acrylate, for which OSHA also has a 10ppm TWA limit. The Agency preliminarily concludes that this limit is necessary to reduce the significant risk of skin irritation and corneal necrosis, which constitute material health impairments that are associated with exposure to butyl acrylate. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. o-sec-BUTYLPHENOL CAS No. 89-72-5; Chemical Formula:

CAS No. 89-72-5; Chemical Form C₂H₅(CH₃)CHC₆H₄OH

H.S. No. 1055

In construction, maritime, and agriculture, OSHA has no limit for o-sec-butylphenol. The ACGIH has a 5-ppm 8-hour TLV*-TWA, with a skin notation. NIOSH has no REL, but concurs (Ex. 8-47, Table N1) with the proposed limit. The proposed PEL for o-sec-butylphenol in the construction, maritime, and agriculture industries is an 8-hour TWA of 5 ppm, with a skin notation. This is the limit recently established for this substance in general industry.

o-sec-Butylphenol is a colorless liquid. It is used as a chemical intermediate for preparing resins, plasticizers, surface active agents, and other products

(ACGIH 1986, p. 84). Animal studies indicate that contact with o-sec-butylphenol causes irritation of the skin, eyes, and respiratory tract and may result in skin burns. A Dow Chemical Company study (1977i, as cited in ACGIH 1986/Ex. 1-3, p. 84) showed that the oral and skin absorption LD50s for guinea pigs ranged between 0.6 and 2.4g/kg. Prolonged contact of o-sec-butylphenol with the skin of these animals resulted in burns, whereas direct application to the eyes did not cause corneal injury. The oral LD₅₀ for rats is 2700 mg/kg (RTECS 1990), and rats exposed to saturated air levels of this chemical survived for seven hours (Dow Chemical Company 1977i, as cited in ACGIH 1986/Ex. 1-3, p. 84). The intravenous LDso for mice is 6 mg/kg (RTECS 1990). Acute workplace exposures to o-sec-butylphenol have resulted in mild respiratory irritation and skin burns (ACGIH 1986/Ex. 1-3, p.

OSHA is proposing an 8-hour TWA limit of 5 ppm for o-sec-butylphenol, with a skin notation, in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that this limit is necessary to protect workers in

construction, maritime, and agriculture from the significant risks of eye and respiratory tract irritation and skin burns potentially associated with exposure to this substance. OSHA believes that eye and mucous membrane irritation and skin burns constitute material health impairments within the meaning of the Act. Promulgation of this limit will also make OSHA's PEL for this substance consistent across all regulated sectors.

CALCIUM HYDROXIDE CAS: 1305–62–0; Chemical Formula: Ca(OH)₂

H.S. No. 1059

In construction, maritime, and agriculture, OSHA has no limit for calcium hydroxide; the ACGIH has a TLV*-TWA of 5 mg/m³. There is no NIOSH REL, but NIOSH concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing a PEL of 5 mg/m³ as an 8-hour TWA for calcium hydroxide in the construction, maritime, and agriculture industries. This is the limit recently established for this substance in general industry.

Calcium hydroxide is a soft, white, odorless, crystalline powder with an alkaline, bitter taste. It is used in building and paving materials, in lubricants, in drilling fluids, in pesticides, and in the manufacture of paper. There are many other industrial uses for this substance (ACGIH 1986, p. 91).

Calcium hydroxide is a moderate to severe caustic and irritant when it comes into contact with the skin, eyes, or mucous membranes of the upper respiratory tract (ACGIH 1986/Ex. 1-3, p. 92; Sax and Lewis 1989, p. 682). The oral LD₅₀ in rats is reported to be 7.34 g/kg (Smyth, Carpenter, Weil et al. 1969/Ex. 1-442). Industrial experience with this substance has not shown a high incidence of adverse health effects, although Sax (1984) reports that it is known to cause dermatitis (p. 621). Calcium hydroxide is also mutagenic (Sax 1984).

In the prior rulemaking, one commenter argued that calcium hydroxide should be regulated as a nuisance dust, i.e., should have a PEL of 10 mg/m³. In response, OSHA stated that the Agency does not agree that calcium hydroxide is a biologically inert substance. Instead, OSHA agrees with Sax (1984), who reports that, "in the form of dust, it [calcium hydroxide] is considered to be an important industrial hazard." OSHA believes that a PEL of 5 mg/m³, half that of the inert particulate limit, is appropriate for this well-known eye, skin, and upper respiratory tract

irritant. OSHA is proposing an 8-hour TWA limit for calcium hydroxide of 5 mg/m³ to protect workers in construction, maritime, and agriculture from the significant risk of skin, eye, and mucous membrane irritation, which OSHA considers material impairments of health. The Agency preliminarily concludes that this limit will reduce these risks substantially. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. CALCIUM OXIDE

CAS: 1305–78–8; Chemical Formula: CaO H.S. No. 1080

In general industry, construction, and maritime, OSHA's 8-hour TWA permissible exposure limit for calcium oxide is 5 mg/m³. There is no limit in agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. The ACGIH TLV* for calcium oxide, which was set on the basis of analogy with sodium hydroxide, a widely recognized sensory irritant, is 2 mg/m³ as an 8-hour TWA. OSHA is proposing a 5-mg/m³ 8-hour TWA PEL for calcium oxide in agriculture. This action will make OSHA's PEL for calcium oxide consistent across all regulated sectors.

Calcium oxide (lime) is a white or grayish-white powder. It is produced when limestone is calcined to drive off carbon dioxide. Calcium oxide is used as a refractory material; as a flux in steelmaking; as a binding agent in building, pulp and paper manufacture, sugar refining, and leather tanning; as the raw material for chlorinated lime bleaching powder, and as a soil treatment in agriculture (Parmeggiani

1983).

The amount of information that has been published specifically about calcium oxide's toxicological effects in animals or humans is limited. In direct contact with tissues, calcium oxide can result in burns and severe irritation because of its high reactivity and alkalinity. The major complaints of workers exposed to lime consist of irritation of the skin and eyes, although inflammation of the respiratory passages, ulceration and perforation of the nasal septum, and even pneumonia have been attributed to inhalation of the dust (ACGIH 1986/Ex. 1-3, p. 92). The Pennsylvania Department of Health reported that strong nasal irritation occurred as a consequence of exposure to a mixture of calcium-oxide-containing dusts at a concentration of approximately 25 mg/m3, but that exposure to concentrations of 9 to 10 mg/m³ produced no observable irritation (Wands 1981a, in Clayton and

Clayton 1981, p. 3054). By comparison, exposure to airborne sodium hydroxide at a concentration of between 0.005 and 0.7 mg/m³ produced burning/redness of the nose, throat, or eyes in workers engaged in cleaning operations (Hervin and Cohen 1973/Ex. 1–945, as cited in NIOSH 1976k/Ex. 1–965). Thus, the demonstrated effect level for sensory irritation caused by exposure to sodium hydroxide is below 1 mg/m³, while that for calcium oxide is above 9 mg/m³.

Based on evidence that exposure to calcium oxide at levels above 9 mg/m3 may cause tearing of the eyes and mucous membrane irritation, OSHA preliminarily concludes that the proposed 8-hour TWA limit of 5 mg/m3 is appropriate for agricultural workplaces. The Agency believes that this limit will protect exposed workers in agriculture from the significant risk of sensory irritation known to occur at concentrations of 9 to 10 mg/m3. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. CARBONYL FLUORIDE CAS: 353-50-4; Chemical Formula: COF2 H.S. No. 1074

In construction, maritime, and agriculture, OSHA has no limit for carbonyl fluoride. The ACGIH has an 8-hour TLV*-TWA of 2 ppm and a 15-minute TLV*-STEL of 5 ppm for this substance. There is no NIOSH REL. The PELS OSHA is proposing for construction, maritime, and agriculture are an 8-hour TWA of 2 ppm and a 15-minute STEL of 5 ppm. NIOSH concurs (Ex. 8-47, Table N1) with these limits, which are identical to those recently established for this substance in general industry.

Carbonyl fluoride is a colorless gas. This substance is used in organic synthesis (Hawley's 1987, p. 223).

The 1-hour LC₅₀ for carbonyl fluoride in rats is 360 ppm, and the 4-hour LC₅₀ for the same species is 90 ppm (ACGIH 1986/Ex. 1–3, p. 111). Carbonyl fluoride hydrolyzes instantly on contact with moisture. The ACGIH (1986/Ex. 1–3, p. 14) reports that carbonyl fluoride is "about as toxic as hydrogen fluoride as a respiratory irritant gas."

Repeated exposure of animals to carbonyl fluoride is known to have metabolic effects; this substance inhibits the fluoride-sensitive enzyme succinic dehydrogenase via hydrolysis of carbonyl fluoride to hydrogen fluoride (Scheel, McMillan, and Phipps 1968/Ex. 1–364). Carbonyl fluoride is described as a "potent" irritant (Sax and Lewis 1989, p. 717).

OSHA is proposing an 8-hour TWA limit of 2 ppm and a 15-minute STEL of 5 ppm for carbonyl fluoride inconstruction, maritime, and agriculture. The Agency preliminarily concludes that both a TWA and a STEL are necessary to provide workers in these sectors with protection against the significant risks of marked irritation and metabolic effects. OSHA considers these effects material health impairments. In addition, promulgation of these limits will make OSHA's PELs for carbonyl fluoride consistent across all regulated sectors. CATECHOL (PYROCATECHOL) CAS: 120-80-9; Chemical Formula: C₆H₄(OH)₂

H.S. No. 1075

In construction, maritime, and agriculture, OSHA has no limit for catechol. The ACGIH has a TLV*-TWA of 5 ppm. There is no NIOSH REL but NIOSH concurs (Ex. 8-47, Table N1) with the limit being proposed. The proposed PEL for this substance in construction, maritime, and agriculture is 5 ppm as an 8-hour TWA. In addition, the Agency is proposing to add a skin notation to the PEL, in accordance with its policy on skin designations, discussed in Section IV.C.16.

Catechol is a colorless crystalline solid that sublimes readily and thus occurs in the vapor state at room temperature. This substance finds use as an antiseptic and in organic synthesis. It is also used in electroplating and photography, and as an ingredient in dyestuffs, specialty inks, antioxidants, and light stabilizers (Hawley's 1987, p. 984).

Catechol is approximately 1.1 to 2.2 times more toxic than phenol, depending on the route of exposure (Industrial Bio-Test Laboratories 1974, as cited in ACGIH 1986/Ex. 1-3, p. 112). The oral LD50 in rats is 300 mg/kg, or approximately half that of phenol. Percutaneous toxicity for catechol in rabbits is 800 mg/kg; catechol's dermal LD₅₀ in rabbits of 0.8 g/kg places this substance in the category of "toxic" by the percutaneous route of administration, as discussed in Section VI.C.16. In addition, the Agency is concerned by reports of catecholinduced central nervous system effects (i.e., convulsions) in humans; this effect is said to occur as a result of skin absorption and to be "more marked" than the CNS effects produced by phenol (Deichmann and Keplinger 1981, in Clayton and Clayton 1981, p. 2586). OSHA is therefore proposing a skin notation for catechol to protect workers in these sectors from the serious CNS effects that may potentially occur from percutaneous absorption of this substance. Eye and nose irritation, as

well as muscular spasms and tremor, have been observed in rats at a concentration of 2800 mg/m3 catechol, indicating that the acute respiratory toxicity of catechol is approximately one-third that of phenol (Industrial Bio-Test Laboratories 1974, as cited in ACGIH 1986/Ex. 1-3, p. 112). In mice, catechol is easily absorbed through the skin and gastrointestinal tract (Forsyth and Quesnel 1957/Ex. 1-978). Additional data document a variety of dermal, respiratory, and systemic toxicities that are closely analogous to those of phenol in their metabolic actions (Harold, Nierenstein, and Roaf 1910/Ex. 1-1111; Dietering 1938/Ex. 1-1019; Cushny et al. 1940, as cited in ACGIH 1986/Ex. 1-3, p. 112). Exposure to catechol causes an increase in blood pressure, and, at high doses, kidney damage, eczematous dermatitis, and systemic illness (Harold, Nierenstein, and Roaf 1910/Ex. 1-1111; Dietering 1938/Ex. 1-1019; Cushny et al. 1940, as cited in ACGIH 1986/Ex. 1-3, p. 112).

Based on this evidence in humans and animals, OSHA is proposing an 8-hour TWA permissible exposure limit of 5 ppm for catechol, with a skin notation, in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that these limits will protect workers in these sectors from the significant risks of dermal and upper respiratory tract irritation, convulsions, and other central nervous system effects, all of which constitute material impairments of health that are potentially associated with exposure to catechol. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

1-CHLORO-1-NITROPROPANE CAS: 600-25-9; Chemical Formula: CH₂CH₂CHClNO₂ H.S. No. 1081

In construction and maritime, OSHA's time-weighted average permissible exposure limit for 1-chloro-1-nitropropane is 20 ppm. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 2 ppm for this substance (ACGIH 1986/Ex. 1-3). There is no NIOSH REL. For construction, maritime, and agriculture, OSHA is proposing a PEL of 2 ppm as an 8-hour TWA, and NIOSH concurs (Ex. 8-47, Table N1) with this limit, which was recently established for this substance in general industry.

1-Chloro-1-nitropropane is a flammable liquid (ACGIH 1986, p. 132.2). This substance finds use as a fungicide (Hawley's 1987, p. 676). When used in pesticidal applications and as directed on the label, this substance is regulated

by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

1-Chloro-1-nitropropane is the most acutely toxic of the fungicides known as the chloronitropropanes. In an inhalation experiment, two rabbits were exposed for 6 hours to a concentration of 393 ppm, after which one rabbit died; at an average concentration of 2574 ppm, both rabbits died. Guinea pigs tested under the same conditions survived these exposures. The oral LD50 in rabbits is between 50 and 100 mg/kg (Machle, Scott, Treon et al. 1945/Ex. 1-349). Other members of this family of fungicides cause a lesser degree of skin and lung irritation but have higher ingestion toxicities (Patty 1963i, as cited in ACGIH 1986/Ex. 1-3, p. 132). Exposure to high concentrations (not further specified) of 1-chloro-1nitropropane can cause heart muscle, liver, and kidney damage (Patty 1963i, as cited in ACGIH 1986/Ex. 1-3, p. 132).

OSHA is proposing an 8-hour TWA PEL of 2 ppm for 1-chloro-1-nitropropane in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect employees in these sectors from the significant risk of skin and upper respiratory tract irritation and of systemic toxicity, which constitute material health impairments within the meaning of the Act. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. COBALT CARBONYL (as Co) CAS: 10210-68-1; Chemical Formula:

Co₂(CO)₄ H.S. No. 1098

In construction, maritime, and agriculture, OSHA has no limit for cobalt carbonyl. The ACGIH has a TLV*-TWA of 0.1 mg/m³ (measured as cobalt) for this substance. There is no NIOSH REL. In construction, maritime, and agriculture, OSHA is proposing a PEL of 0.1 mg/m³ as an 8-hour TWA (measured as cobalt), and NIOSH concurs (Ex. 8-47, Table N1) with this limit. This is the limit recently established for this substance in general industry.

Cobalt carbonyl takes the form of orange or brown crystals (Weast 1984, p. B-89). It is formed by vacuum sublimation.

Sax and Lewis (1989, p. 938) report that the LC_{50} in mice is 27 mg/m³ for 2 hours. The oral LD_{50} in mice is 377.7 mg/kg; in rats, it is 753.8 mg/kg (Spiridonova and Shabalina 1973/Ex. 1–1098). Exposure to cobalt carbonyl causes chemical pneumonitis (Stokinger 1981e). The hazards of exposure to the metal

carbonyls range from relatively low (for iron pentacarbonyl) to extremely serious (for nickel carbonyl) (Stokinger 1981e, in Clayton and Clayton 1981, pp. 1797–1806); the greater the toxicity of the metal and the more stable and volatile the carbonyl, the more hazardous the compound. Exposure to any of the metal carbonyls causes the same symptoms of nausea, dizziness, headache, substernal pain, coughing, and dyspnea (Stokinger 1981e). Evidence concerning any chronic effects of long-term exposure is lacking (ACGIH 1986/Ex. 1–3, p. 145).

OSHA is proposing an 8-hour TWA PEL of 0.1 mg/m³ for cobalt carbonyl in construction, maritime, and agriculture to protect against the significant risk of headache, nausea, and pulmonary effects, all of which are material impairments of health that are associated with occupational exposure to this substance. The Agency preliminarily concludes that this limit is necessary to substantially reduce these significant risks among workers in these sectors. In addition, promulgation of this limit will make OSHA's PEL for cobalt carbonyl consistent across all regulated sectors.

COBALT HYDROCARBONYL (as Co) CAS: 16842-03-8; Chemical Formula: HCo(CO)₄ H.S. No. 1099

In construction, maritime, and agriculture, OSHA has no limit for cobalt hydrocarbonyl. The ACGIH has a TLV*-TWA of 0.1 mg/m³ (measured as cobalt) for this substance. There is no NIOSH REL. OSHA is proposing an 8-hour TWA PEL of 0.1 mg/m³ for cobalt hydrocarbonyl (measured as cobalt) in construction, maritime, and agriculture; NIOSH concurs (Ex. 8-47, Table N1) with this limit, which was recently established for cobalt hydrocarbonyl in general industry.

Cobalt hydrocarbonyl is a gas that behaves like a strong acid and decomposes rapidly in air (Clayton and Clayton 1981, pp. 1793–1796). Cobalt hydrocarbonyl is the catalyst for the OXO process that converts olefins to oxidized products (Clayton and Clayto 1981, p. 1795).

Cobalt hydrocarbonyl is approximately half as toxic as nickel carbonyl in terms of acute effects; in animals, it produces clinical signs and symptoms very similar to those produced by nickel carbonyl (OSHA PEL of 0.007 mg/m³) and iron pentacarbonyl (OSHA PEL of 0.8 mg/m³) (ACGIH 1986/Ex. 1–3, p. 145). These include headache, dizziness, and, after a delay in onset, liver, brain, and lung damage. The 30-minute LC₅₀ in rats is

46.2 mg/m³ (RTECS 1990). There is no evidence of chronic toxicity or of

carcinogenicity.

OSHA is proposing an 8-hour TWA limit of 0.1 mg/m³ for cobalt hydrocarbonyl in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect exposed employees in these sectors from the significant risk of pulmonary, brain, and liver damage, as well as acute effects such as headaches and dizziness, all of which constitute material health impairments. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. CRESOL (all isomers)

CAS: 1319-77-3; Chemical Formula: CH₃C₆H₄OH H.S. No. 2042

In general industry, construction, and maritime, OSHA's permissible exposure limit for all cresol isomers is 5 ppm (22 mg/m3) as an 8-hour TWA; this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. There is no limit in agriculture. The ACGIH has a TLV --TWA of 5 ppm, and a skin notation, for cresol. NIOSH has a REL for this substance of 10 mg/m3 (2.3 ppm) as a 10-hour TWA. OSHA is retaining its PEL and skin notation for cresol in construction and maritime and is proposing to extend the PEL and notation to agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHAregulated sectors.

Cresol is a colorless, yellowish, or pinkish liquid with a phenol-like odor. The commercially available substance is a mixture of the ortho-, meta-, and paraisomers, which derive from coal tar or petroleum. Cresol is used in the manufacture of herbicides and synthetic resins; as a disinfectant and fumigant; in photographic developers and explosives: as a textile scouring agent, surfactant, organic intermediate, and metal degreaser; and in synthetic food flavoring (ACGIH 1986, p. 148; Hawley's 1987, p. 320; HSDB 1991). The cresols have wide application in the agricultural industries (Clayton and Clayton 1981, p. 2597). When used in pesticidal applications and in accordance with directions on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Cresol causes eye, nose, and skin irritation, central nervous system effects, cardiovascular effects, and liver and kidney injury in humans and animals In rats, the oral LD₅₀ for ortho-

cresol is 121 mg/kg; in mice, the oral LDso is 344 mg/kg (RTECS 1990). The dermal LDso in rabbits is 890 mg/kg for the ortho-isomer (RTECS 1990 "o-Cresol"). For meta-cresol, the oral LDso values are 242 mg/kg and 828 mg/kg for rats and mice, respectively, and the dermal LDso in rabbits is 517 mg (RTECS 1990 "m-Cresol"). The oral LD50 values for para-cresol in rats and mice are 207 mg/kg and 344 mg/kg, respectively, and the dermal LDse in rabbits is 301 mg/kg (RTECS 1990 "p-Cresol"). Instilled into the eyes of rabbits, doses of cresol ranging from 103 to 105 mg in the eyes or of 517 to 524 mg placed in contact with the skin of rabbits for 24 hours caused severe irritation (RTECS 1990). Rats dermally exposed to cresol at a dose of 1.0 to 1.7 ml/kg for 1 to 2 hours developed skin discoloration and died (Campbell 1941, in Soap Sanit. Chem. 17:103-111, in NIOSH Criteria Document 1978, p. 59). Exposure to saturated airborne concentrations of cresol for 1 hour per day for 10 days caused eye and nose irritation and some deaths in mice (Campbell 1941, as above). A single oral dose of 1300 to 2700 mg/kg of p-cresol caused twitching, comas, and death in rats (Deichmann, Witherup 1944, in J. Pharmacol. Exp. Ther. 80:233-240). A group of rats exposed to concentrations of 0.05 or 0.0052 mg/m3 of tricresol (a mixture of the three isomers) for 3 months showed decreased weight gain, increased central nervous system excitability and oxygen consumption, histologic changes in the lungs and liver. and decreases in the gamma-globulin content of the serum in the high-dose group; no significant changes were seen in the low-dose group (Kurlyandskiy et al. 1975, in Gig. Sanit. 5:85-87). Guinea pigs inhaling 9.0 mg/m3 of o-cresol over a 4-month period showed changes in their ECGs, and rats exposed to the same concentration on this regimen developed both hematological and central nervous system changes (NIOSH Criteria Document 1978, p. 60).

In humans, acute exposure to cresol by any route can cause muscular weakness, gastroenteric disturbances, severe depression, collapse, lung edema, and injury to the pancreas and spleen. Fatal poisoning may occur by skin absorption if a large body area is involved (Windholz 1983, p. 369). Oral exposure to 8 g or more of cresol produces rapid circulatory collapse and is followed by death (Windholz 1983, p. 369). Eight of 10 workers exposed to 1.4 ppm o-cresol experienced upper respiratory tract irritation (NIOSH Criteria Document 1978, p. 57). Cresol is a severe skin irritant and a frequent cause of skin discoloration and dermatitis among exposed workers

(Sittig 1985, pp. 263–284). Chronic effects from cresol exposure include skin problems, central nervous system changes, and possible liver and kidney damage (Rom 1983, p. 528). Seven workers exposed to cresol for 1.5 to 3 years at unspecified concentrations had headaches and frequent nausea and vomiting. Four of the workers experienced elevated blood pressure, impaired kidney function, a blood calcium imbalance, and marked tremors (NIOSH Criteria Document 1978, p. 117).

Based on this evidence in humans and animals, OSHA preliminarily concludes that cresol causes primary irritation, central nervous system effects. cardiovascular effects, and liver and kidney injury. OSHA believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that the proposed limit for cresol of 5 ppm as an 8-hour TWA, with a skin notation, is necessary to substantially reduce the risks of material health impairment among agricultural workers. In addition, promulgation of this limit will make the PEL for cresols consistent across all OSHA-regulated sectors.

CROTONALDEHYDE

CAS: 4170–30–3; 123–73–9 (trans-isomer); Chemical Formula: CH₂CH=CHCHO H.S. No. 2043

In general industry, construction, and maritime, OSHA's permissible exposure limit for crotonaldehyde is 2 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 2 ppm for this substance; NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 2 ppm for crotonaldehyde in agriculture. This is the limit recently established for this substance in general industry.

Crotonaldehyde is a colorless, flammable liquid with a strong, pungent odor. It turns a pale yellow color in contact with air or light. The commercially available product consists more than 95 percent of the transisomer. Crotonaldehyde is primarily used as an intermediate in the manufacture of n-butanol; this substance is also used in pesticide compounds, in chemotherapeutic agents, as a warning agent in fuel gases, as a solvent, and to locate breaks and leaks in pipes (HSDB 1988; ACGIH 1986, p. 149; AIHA 1988). When used in pesticidal applications and in accordance with directions on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Crotonaldehyde is an irritant of the eyes, mucous membranes, respiratory system, and skin in both animals and humans. Central nervous system effects have been observed in exposed animals, and sensitization may occur in humans. The oral LDso in rats is 206 mg/kg, the 2hour LC50 in rats is 200 mg/m3, and the dermal LDso in rabbits is 380 mg/kg (RTECS 1990; AIHA 1988). Death occurred in rats exposed to a 1650-ppm concentration of crotonaldehyde for 10 minutes; acutely poisoned animals developed respiratory distress, excitation, and terminal convulsions, and autopsy revealed bronchiolar damage (Rinehart 1967). A single exposure to a 10-ppm concentration of crotonaldehyde for 20 minutes produced a measurable change in pulmonary performance in rats (Rinehart 1967). In contact with the skin of rabbits, crotonaldehyde caused mild irritation (RTECS 1990). The damage caused to the eyes of rabbits by liquid crotonaldehyde is severe (Grant 1986, p. 284). The mortality observed among rats in a 13-week gavage study was attributed to the corrosive action of crotonaldehyde; stomach lesions included hyperplasia of the forestomach epithelium, forestomach hyperkeratosis, ulcers, moderate necrosis, and acute inflammation (Wolfe, Rodwin, French et

Volunteers exposed for 15 minutes to a 4.1-ppm concentration of crotonaldehyde reported irritation of the nose and upper respiratory tract, and lacrimation was experienced after 30 seconds of exposure to this concentration (Sim and Pattle 1957). In eight cases of corneal injury in workers handling crotonaldehyde, complete healing occurred within 48 hours of the incident (Grant 1986, p. 284). A laboratory worker who handled small amounts of crotonaldehyde reportedly developed a sensitization reaction to this substance (ACGIH 1986, p. 149), and patch testing of a textile worker confirmed sensitization to crotonaldehyde (Shmunes and Kempton 1980).

Based on this evidence, OSHA preliminarily concludes that, in the absence of a permissible exposure limit, workers in agriculture are at significant risk of experiencing the eye, mucous membrane, respiratory system, and skin irritation associated with exposure to crotonaldehyde. The Agency believes that establishing an 8-hour TWA PEL of 2 ppm is necessary to substantially reduce this risk among agricultural workers. In addition, promulgation of this limit will make OSHA's PEL for this

substance consistent across all regulated sectors. DEMETON (Systox) CAS: 8065-48-3; Chemical Formula: C₈H₁₉O₃PS₂ H.S. No. 2049

In general industry, construction, and maritime, OSHA's permissible exposure limit for demeton (also called Systox) is 0.1 mg/m3 as an 8-hour TWA; this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. There is no limit in agriculture. The ACGIH has an 8-hour TLV*-TWA of 0.1 mg/m3, with a skin notation, for this substance; this limit was established by analogy with parathion. NIOSH has no REL for demeton but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing a PEL of 0.1 mg/m3 as an 8-hour TWA, and a skin notation, for demeton in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHAregulated sectors.

Demeton is a light brown to pale yellow oil with a sulfur-like odor; it is a mixture of two isomers. Demeton is a systemic insecticide and acaricide used against sap-feeding insects and mites (ACGIH 1986, p. 170; Hayes 1982, p. 389). When used in pesticidal applications and in accordance with directions on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Demeton causes cholinesterase inhibition, including respiratory and ocular effects, cyanosis, and central nervous system effects. The oral LDs values in rats and mice are 1700 μg/kg and 7850 µg/kg, respectively (RTECS 1990). The dermal LD50 in rabbits is 24 mg/kg (RTECS 1990). Rats fed 50 ppm demeton in the diet became sick but recovered after 3 to 4 weeks despite continued feeding of demeton (Barnes and Denz 1954, in Hayes 1982, p. 389). A dietary level of 5 ppm (0.149 mg/kg/day) caused erythrocyte cholinesterase inhibition in dogs; plasma cholinesterase inhibition was marked at 5 ppm and slight at 2 ppm (Frawley and Fuyat 1957, in Hayes 1982, p. 389). A single exposure to a concentration of 18 mg/m3 demeton was fatal to all of six rats exposed; the deaths occurred from 50 to 90 minutes after the exposure (Deichmann and Rakoczy 1955, in ACGIH 1986, p. 170). Seventeen rats exposed to a 3 mg/m3 concentration of demeton showed no signs of illness after the first exposure; following the second exposure, however, tremors were observed, and the fourth exposure caused death in 10 of the 17 rats (Deichmann and Rakoczy 1955, in

ACGIH 1986, p. 170). Doses of 7 to 10 mg/kg administered to pregnant mice during days 7 to 11 of pregnancy produced reproductive, developmental, and embryonic effects in mice (RTECS 1990).

In humans, several cases of demeton intoxication have been reported. The lowest lethal oral dose reported for humans is 171 µg/kg (RTECS 1990). The first signs and symptoms of demeton intoxication are respiratory and ocular effects, which may include a feeling of tightness in the chest, wheezing, laryngeal spasm, excessive salivation, miosis, blurred distant vision, tearing, rhinorrhea, and frontal headache (Proctor, Hughes, and Fischman 1988, p. 176). Ingestion of demeton causes symptoms, such as anorexia, nausea, vomiting, abdominal cramps, and diarrhea, which usually appear within 15 minutes to 2 hours (Proctor, Hughes, and Fischman 1988, p. 176). Absorption of demeton through the skin results in localized sweating and muscular fasciculations within 15 minutes to 4 hours after exposure (Proctor, Hughes, and Fischman 1988, p. 176). Five volunteers given oral doses of 7.125 mg/ day (about 0.1 mg/kg/day) for 25 days showed a depression of plasma and erythrocyte cholinesterase activity of 39.8 and 15.9 percent, respectively (Moeller and Rider 1965; Rider et al. 1969, in Hayes 1982, p. 389). A 16-yearold boy exposed to demeton while spraying hops was unconscious for 6 hours; 5 weeks after treatment with atropine he continued to complain about difficulty in breathing, general weakness, and lack of coordination in walking. After 3 months, the boy still had autonomic nervous system disturbances (Klimkova-Deutschova 1959, in Hayes 1982, p. 390). Twelve of 14 workers exposed to demeton in the air during aerial spraying of cotton and wheat had decreased cholinesterase levels but no signs of poisoning; demeton levels in the air breathed by these workers approached a concentration of 1 mg/m3 (Kagan 1956, in Hayes 1982, p. 390). Levels ranging from 4.3 to 6 mg/m3 were reported to have caused a reduction in the serum cholinesterase activity of workers applying demeton to trees, but no other signs or symptoms of intoxication were reported (Kagan et al. 1958, in Hayes 1982, p. 390).

Based on this evidence in humans and animals, OSHA preliminarily concludes that demeton causes cholinesterase inhibition and concomitant poisoning. OSHA preliminarily finds that, in the absence of a limit, workers in agriculture are at significant risk of

experiencing these adverse health effects. The Agency believes that establishing an 8-hour TWA PEL of 0.1 mg/m³, and a skin notation, for demeton in agriculture is necessary to significantly reduce this risk of material health impairment. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

DIAZINON
CAS: 333-41-5; Chemical Formula:
C₁₂H₂; N₂O₃PS
H.S. No. 1118

OSHA has no limit for diazinon in construction, maritime, or agriculture. The ACGIH has a TLV®-TWA of 0.1 mg/m³, with a skin notation. There is no NIOSH REL. OSHA is proposing a PEL for diazinon in construction, maritime, and agriculture of 0.1 mg/m³ as an 8-hour TWA, with a skin notation; NIOSH concurs (Ex. 8-47, Table N1) that this limit is appropriate. This is the limit recently established for this substance in general industry.

Pure diazinon is a colorless liquid, but the technical grade is pale yellow to dark brown in color and has a faint odor. Diazinon is an insecticide that is used against fire ants (Hawley's 1987, p. 364). When used in pesticidal applications and in accordance with directions on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide

Act (FIFRA).

Gaines (1960/Ex. 1-319) reports the acute oral LD50 for male and female rats to be 108 and 76 mg/kg, respectively. Other reports set the acute oral LDsos in rats, guinea pigs, and rabbits at 76 to 150, 240 to 320, and 130 mg/kg. respectively (Association of American Pesticide Control Officials, Inc. 1969, as cited in ACGIH 1986/Ex. 1-3, p. 172). The dermal LDso in rabbits is 400 mg/kg (RTECS 1990). Susceptibility to repeated doses is relatively consistent among species, with dogs showing signs of poisoning at 9.3 mg/kg per day and rats showing complete inhibition of red blood cell cholinesterase and marked inhibition of brain cholinesterase at 50 mg/kg/day (Bruce, Howard, and Elsea 1955/Ex. 1-585). Monkeys were poisoned at diazinon doses of 5 mg/kg/ day (Woodard, Woodard, and Cronin 1968/Ex. 1-458). Feeding studies in rats have shown no chronic toxicity at 10, 100, or 1000 ppm. For many mammals, diazinon is less toxic than parathion (ACGIH TLV®-TWA of 0.1 mg/m3). although this is not true under some circumstances (ACGIH 1986/Ex. 1-3, p.

In humans, Hayes (1963/Ex. 1-982) reports that two patients were poisoned

by a dermal diazinon dosage of about 1.1 mg/kg; however, Gassman (1957/Ex. 1-901) reports no ill effects from an accidental ingestion of 30 mg/kg. One man received a dose of 250 mg/kg and recovered after treatment, which included gastric lavage (Bockel 1967, as cited in ACGIH 1986/Ex. 1-3, p. 172). In tests, Geigy (1966, as cited in ACGIH 1986/Ex. 1-3, p. 172) found that a series of doses of 0.05 mg/kg/day for 28 days produced plasma cholinesterase inhibition, and it has been suggested that the no-effect level for cholinesterase inhibition in humans is 0.02 mg/kg/day. Skin absorption of diazinon occurs readily, and overexposures are associated with weakness, headache, blurred vision, salivation, sweating, nausea, vomiting, diarrhea, abdominal cramps, slurred speech, and moist rales in the lungs (ACGIH 1986/Ex. 1-3, p. 172).

The Agency is proposing an 8-hour TWA PEL of 0.1 mg/m3, with a skin notation, for diazinon in construction, maritime, and agriculture. OSHA preliminarily concludes that these limits will protect exposed workers in these sectors from the significant risk of cholinesterase inhibition, weakness, headache, nausea, vomiting, as well as the other symptoms and signs of diazinon poisoning, which together constitute material health impairments that are associated with exposure to this substance. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all

regulated sectors.

1,1-DICHLORO-1-NITROETHANE CAS: 594-72-9; Chemical Formula: CH₂CCl₂NO₂ H.S. No. 1121

In construction and maritime, OSHA currently has a ceiling limit of 10 ppm for 1,1-dichloro-1-nitroethane. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 2 ppm for this substance. There is no NIOSH REL, but NIOSH concurs (Ex. 8-47, Table N1) with the proposed limit. OSHA is proposing an 8-hour TWA PEL of 2 ppm for 1,1-dichloro-1-nitroethane in the construction, maritime, and agriculture industries. This is the limit recently established for 1,1-dichloro-1-nitroethane in general

1,1-Dichloro-1-nitroethane is a colorless liquid. It is used in organic synthesis and as a fumigant for produce. When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Toxicity data on 1,1-dichloro-1nitroethane are largely derived from the 1945 studies conducted by Machle and co-workers (Ex. 1-349). These scientists reported that both rabbits and guinea pigs died from inhaling vapors at 100 ppm for 6 hours; at a concentration of 60 ppm, the animals survived a 2-hour exposure. Four-hour inhalation exposures at 34 ppm and 8-hour daily exposures at 25 ppm for a total of 204 hours also did not kill rabbits or guinea pigs. Skin and mucous membrane irritation were not produced at the 25ppm exposure level. At survival concentrations, the primary targets of toxicity were the lungs, which showed edema, congestion, hemorrhage, and acute bronchitis. At lethal exposures, these investigators observed acute myocardial degeneration with interstitial edema, cloudy swelling of the liver with cellular degeneration, and tubular degeneration and interstitial edema of the kidney, as well as edema of the tufts of the glomeruli and kidney necrosis. The compound was also found to be a severe skin irritant when two applications were applied on two successive days (Machle, Scott, Treon et al. 1945/Ex. 1-349). The ACGIH (1986/ Ex. 1-3, p. 188) states that dichloronitroethane is more toxic than the nonchlorinated nitroalkanes.

OSHA is proposing a PEL of 2 ppm TWA for 1,1-dichloro-1-nitroethane in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risk of irritation, lung injury, and liver and kidney damage, all material health impairments that are associated with exposure to this substance. In addition, promulgation of this limit will make OSHA's PEL for 1,1-dichloro-1-nitroethane consistent across all regulated sectors.

p-DICHLOROBENZENE CAS: 108-48-7; Chemical Formula: C₈H₄Cl₂ H.S. No. 1125

In construction and maritime, OSHA has an 8-hour TWA limit of 75 ppm for p-dichlorobenzene. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 75 ppm and a TLV*-STEL of 110 ppm for this substance. NIOSH has no REL for p-dichlorobenzene. In construction and maritime, OSHA is retaining the 75-ppm TWA limit and proposing to add a STEL of 110 ppm for p-dichlorobenzene; the Agency is also proposing to extend these limits to agriculture. These are the limits recently established for p-dichlorobenzene in general industry.

p-Dichlorobenzene is a white, crystalline solid with a camphor-like

odor. It is used as a fumigant to control mildew and molds (ACGIH 1986, p. 187). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

In animal studies, an injection of 0.005 gram of p-dichlorobenzene in rats caused slight liver necrosis (Cameron, Thomas, Ashmore et al. 1937/Ex. 1-471). The intraperitoneal LD50 for rats is 2562 mg/kg (Zupko and Edwards 1949/Ex. 1-878). The oral LDso in mice is 2950 mg/kg (Domenioz 1946, as cited in ACGIH 1986/Ex. 1-3, p. 179); in rats, the oral LDso is 2512 mg/kg (Varshavskaya 1970, as cited in ACGIH 1986/Ex. 1-3, p. 179). Rabbits fed a daily dietary dose of 5 grams developed opacity of the lens in 3 weeks (Berliner 1939/Ex. 1-715); this finding was not confirmed, however, in repeated studies (Pike 1944/Ex. 1-658).

Reports of a human inhalation exposure to unspecified levels of pdichlorobenzene describe swelling of the feet, ankles, and hands after daylong use of a mothproofing agent consisting of this substance (Clayton 1935/Ex. 1-306). Other reports describe cataracts caused by exposure to unspecified concentrations of the vapor of p-dichlorobenzene (Berliner 1939/Ex. 1-715). Petit and Champaix (1948, as cited in ACGIH 1986/Ex. 1-3, p. 179) report the case of a woman who experienced tingling of the hands, vertigo, and loss of weight from working for 18 months with a mixture of 90 parts p-dichlorobenzene and 10 parts hexachloroethane (airborne concentration not specified).

Based on this evidence. OSHA is retaining the 8-hour TWA PEL of 75 ppm TWA in construction and maritime and is proposing to add a STEL of 110 ppm for p-dichlorobenzene in these sectors; the Agency is also proposing to extend these limits to agriculture. OSHA preliminarily concludes that both a TWA and a STEL are necessary to protect workers in these sectors from the significant risk of eye damage. vertigo, and neuropathic effects, which constitute material impairments of health within the meaning of the Act. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

DICHLOROMONOFLUOROMETHANE CAS: 75-43-4; Chemical Formula: CHCL.F

H.S. No. 1128

In construction and maritime, OSHA has a limit of 1000 ppm as an 8-hour TWA for dichloromonofluoromethane (FC-21). There is no limit in agriculture.

The ACGIH has a TLV*-TWA of 10 ppm 1-82; Belej and Aviado 1975/Ex. 1-462). for this substance; this limit is based on FC-21's similarity to chloroform in terms of hepatotoxic effects. There is no NIOSH REL. In construction, maritime, and agriculture, OSHA is proposing a TWA PEL for FC-21 of 10 ppm, and NIOSH concurs (Ex. 8-47, Table N1) with this limit. This is the limit recently established for FC-21 in general

Dichloromonofluoromethane is a colorless gas. It is used as a solvent and refrigerant (Hawley's 1987, p. 379).

FC-21 is considered more toxic than the related difluorinated methanes. The major health hazards associated with exposure to this substance are liver damage, cardiac sensitization, and narcosis. Freon-21 has a 4-hour LC50 of 49,900 ppm in rats (Tappan and Waritz 1964, as cited in ACGIH 1986/Ex. 1-3, p. 187). Within an hour, exposure to 100,000 ppm killed rats and guinea pigs (Weigand 1971/Ex. 1-1102); other tests with guinea pigs and mice demonstrated that concentrations of 50,000 ppm and higher cause unconsciousness or death (Nuckolls 1935, as cited in ACGIH 1986/ Ex. 1-3, p. 187; Booth and Bixby 1932/ Ex. 1-1079). The clinical signs of overexposure include loss of coordination, tremors, narcosis, and prostration, as well as possible lung and liver changes (Tappan and Waritz 1964, as cited in ACGIH 1988/Ex. 1-3, p. 187).

Two-week exposures of rats to 10,000 ppm for 6 hours daily caused hepatic failure or marked liver damage (Trochimowicz, Moore, and Chiu 1977/ Ex. 1-34). A series of 90-day exposures of rats and dogs to concentrations of

1000 or 5000 ppm dichloromonofluoromethane resulted in bilateral hair loss, cirrhosis, and excessive mortality in rats at both exposure levels; dogs exhibited weight loss at both levels, but mild liver changes were observed only at the 5000ppm level (Trochimowicz, Lyon, Kelly, and Chiu 1977, as cited in ACGIH 1986/ Ex. 1-3, p. 187). Another uncompleted study reported liver pathology in rats repeatedly exposed for 90 days at 500 ppm, and probable liver pathology from similar exposures to 200 ppm; no hepatic effects were observed after exposure to 50 ppm (Allied Chemical Company 1978, as cited in ACGIH 1986/Ex. 1-3, p. 187).

Two of 12 dogs exposed to 10,000 ppm FC-21 plus intravenous epinephrine developed serious arrhythmias (Mullin, as cited in ACGIH 1988/Ex. 1-3, p. 187). Dogs and monkeys (anesthetized) demonstrated tachycardia and hypotension after exposure to FC-21 at levels between 50,000 and 100,000 ppm: bronchoconstriction was observed at 25,000 ppm (Aviado and Smith 1975/Ex.

Anesthetized mice exposed to a concentration of 100,000 ppm FC-21 showed arrhythmia and cardiac sensitization to epinephrine (Aviado and Belej 1974/Ex. 1-615). Pre-implantation loss has been reported in pregnant rats exposed to FC-21 at 10,000 ppm on days 6 through 15 of gestation (Belej and Aviado 1975/Ex.1-462).

OSHA is proposing a TWA limit of 10 ppm for dichloromonofluoromethane in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risks of hepatotoxic effects, cardiac sensitization, and narcosis associated with exposure to this substance. OSHA believes that these exposure-related effects constitute material impairments of health within the meaning of the Act. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

DIETHYL KETONE CAS: 96-22-0; Chemical Formula: C2H5COC2H5 H.S. No. 1135

OSHA has no limit for diethyl ketone in construction, maritime, or agriculture. The ACGIH has a TLV®-TWA of 200 ppm for this substance. There is no NIOSH REL. The proposed PEL in construction, maritime, and agriculture is 200 ppm as an 8-hour TWA, and NIOSH concurs (Ex. 8-47, Table N1) with this limit. This is the limit recently established for diethyl ketone in general industry.

Diethyl ketone is a colorless liquid with an acetone-like odor. This substance is used in medicine and in organic synthesis (Hawley's 1987, p.

The oral LD50 for diethyl ketone in rats is reported to be 2.14 g/kg. Four of six rats died when exposed to diethyl ketone for four hours at 8000 ppm (Smyth, Carpenter, Weil, and Pozzani 1954/Ex. 1-440). In general, the toxicities of the methyl ketones increase with increasing molecular weight; diethyl ketone is somewhat less toxic than is methyl propyl ketone (TLV*-TWA of 200 ppm) (NIOSH 1978f, as cited in ACGIH 1986/Ex. 1-3, p. 199). Like all of the ketones, exposure to diethyl ketone causes mucous membrane and eye and skin irritation.

In construction, maritime, and agriculture, OSHA is proposing an 8hour TWA PEL of 200 ppm for diethyl ketone, the same limit being proposed for methyl propyl ketone. The Agency preliminarily concludes that this limit is necessary to reduce the significant risk of eye and skin irritation, which are material health impairments that are associated with exposure to diethyl ketone. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

DIETHYLENE TRIAMINE CAS: 111-40-0; Chemical Formula: (NH₂CH₂CH₂)₂ NH

H.S. No. 1138

OSHA has no limit for diethylene triamine (DETA) in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 1 ppm, with a skin notation, for this substance. There is no NIOSH REL. OSHA is proposing a PEL of 1 ppm as an 8-hour TWA for diethylene triamine in construction, maritime, and agriculture, and NIOSH concurs (Ex. 8-47, Table N1) with this limit. This is the limit recently established for this substance in general industry.

Diethylene triamine is a yellow liquid that has an ammonia-like odor. This substance is used as a solvent, fuel component, and saponification agent

(Hawley's 1987, p. 391).

The acute intraperitoneal LD₅₀ values for DETA are reported to be 71 and 74 mg/kg for the mouse and rat, respectively (Hine, Kodama, Anderson et al. 1958/Ex. 1–511). In the rat, the reported oral and percutaneous LD₅₀ values are the same (1080 mg/kg); the dermal LD₅₀ for the rabbit is 1090 mg/kg (Smyth, Carpenter, and Weil 1949/Ex. 1–528). Exposure to 300 ppm of diethylene triamine vapor for 8 hours failed to kill any of a group of exposed rats (Savitt 1955/Ex.1–663).

Sutton (1963/Ex. 1-1101) has reported that DETA causes severe corneal injury; solutions of 15 to 100 percent caused lasting corneal damage. If improperly controlled, the vapor and liquid cause sensitization of the respiratory tract and skin (American Industrial Hygiene Association 1960, as cited in ACGIH 1986/Ex. 1-3, p. 197). Dernehl (Ex. 1-728) demonstrated such sensitization in a

study reported in 1951.

OSHA is proposing an 8-hour TWA limit of 1 ppm for diethylene triamine in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risk of skin and respiratory tract irritation and sensitization, all of which constitute material health impairments that are associated with occupational exposure to diethylene triamine. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

DINITROBENZENE (ALL ISOMERS)
CAS: 528-29-0; 99-65-0; 100-25-4;
Chemical Formula: C₆H₄(NO₂)₂
H.S. No. 2071

In general industry, construction, and maritime, OSHA's permissible exposure limit for all isomers of dinitrobenzene is 1mg/m3 as an 8-hour TWA; this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. There is no limit in agriculture. The ACGIH has an 8-hour TLV*-TWA of 1 mg/m3, with a skin notation, for the dinitrobenzene isomers. NIOSH has no REL for dinitrobenzene but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 1 mg/ m3 for dinitrobenzene (all isomers) in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

The ortho- and para-isomers of dinitrobenzene are white crystals; the meta isomer takes the form of pale yellow crystals. Dinitrobenzene is used as a camphor substitute in the production of celluloids, in the manufacture of dyes, and in organic synthesis (ACGIH 1986, p. 214; Merck 1983, p. 477). The industrial product is usually a mixture of the three isomers (Clayton and Clayton 1981, p. 2455).

Dinitrobenzene causes eye and respiratory tract irritation, cyanosis, aplastic anemia, and liver damage in humans and animals and, in animals, testicular damage (NIOSH 1989, in J. Appl. Toxicol. 9(3):199-202). The oral LD50 for m-dinitrobenzene is 83 mg/kg in rats, and the lowest lethal oral dose of p-nitrobenzene in cats is 29 mg/kg (RTECS 1990). There are no acute toxicity data for the ortho-isomer. Dinitrobenzene is known to be readily absorbed through the skin, although specific toxicity data are not available. Rats were given a single oral dose of the m-isomer (20 mg/kg) showed cyanosis and methemoglobinemia (NIOSH 1989). Four or five 20 mg/kg doses caused ataxia (NIOSH 1989). m-Dinitrobenzene given orally to rats as a 1 percent suspension in corn oil caused signs and symptoms such as a reduction in ambulatory motion, ataxia, weakness, dyspnea, rapid heartbeat, cyanosis, coma, and respiratory failure (Cody et al. 1981, in HSDB 1985). The effects on male and female rats of oral dosing with 200 mg/l m-dinitrobenzene included reduced growth rates, weight loss, reductions in hematocrit and hemoglobin values, enlarged spleens, testicular atrophy in males, and yellow pigmentation of liver cells (Cody et al.

1981, in HSDB 1985). Rats were given single oral doses (50 mg/kg) of each of the dinitrobenzene isomers; only the mand p-isomers caused visible cyanosis within 2 hours and enlarged spleens observable at autopsy, and only the misomer caused a statistically significant decrease in testis weight (Blackburn, Gray, Lloyd, Sheard, & Foster 1988, in Toxicol. Appl. Pharmacol. 92(1):54-64). In another experiment, rats were given single oral 48 mg/kg doses of dinitrobenzene and their testes were examined histologically at intervals of 1 to 175 days thereafter. The authors concluded that acute exposure to dinitrobenzene causes rapid and extensive disruption of spermatogenesis as well as lesions and occlusion of the seminiferous tubules (Hess, Linder, Struder, & Perrcault 1988, in J. Androl. 9(5):327-342).

Most signs and symptoms of overexposure to dinitrobenzene in humans are attributable to the loss of the blood's oxygen-carrying capacity (Proctor, Hughes, and Fischman 1988, p. 215). The onset of symptoms may be delayed for up to 4 hours, and the first effect may be an increasingly intense headache (Hamblin 1963, in Proctor, Hughes, and Fischman 1988, p. 215). Symptoms of weakness and dizziness occur at methemoglobin concentrations of 40 percent; methemoglobin concentrations of 70 percent cause ataxia, dyspnea, tachycardia, nausea, vomiting, and drowsiness (Hamblin 1963, in Proctor, Hughes, and Fischman 1988, p. 215). Coma occurs at levels above 70 percent; the lethal level is in the range of 85 to 90 percent methemoglobin (Chemical Safety Data Sheet SD-21 1967, in Proctor, Hughes. and Fischman 1988, p. 215). Alcohol ingestion increases the toxic effects of dinitrobenzene (Proctor, Hughes, and Fischman 1988, p. 215). The principal clinical sign of dinitrobenzene intoxication is cyanosis, which occurs at a methemoglobin concentration of 15 percent or more (Gosselin, Smith, and Hodge 1984, p. II-213; Hamblin 1983, in Proctor, Hughes, and Fischman 1988, p. 215). Workers exposed to dinitrobenzene have reported symptoms including a burning sensation in the mouth, dry throat, thirst, and, with more intense exposure, somnolence, staggering gait, and coma (von Oettingen 1941, in Proctor, Hughes, and Fischman 1988, p. 215). In munitions factories, exposure to dinitrobenzene has been associated with toxic hepatitis and aplastic anemia; other symptoms reported in these cases included headache, burning pain and parethesias in the feet, ankles, hands, and forearms,

and visual effects (Grant 1986, p. 356; Ellenhorn and Barceloux 1988, in HSDB 1989). Workers exposed to m-dinitrobenzene dust in 1969 developed cyanosis and experienced slight to moderate anemia; 10 years later in a follow-up on the same workers, no long-term adverse effects were seen (Okubo and Shigeta 1982, in HSDB 1985). In chronically exposed workers, vision impairment appears to be common; symptoms included contracted visual fields and reduced-visual acuity with central scotomas (Hubner 1918; Lewin and Guillery 1913, in Grant 1986, p. 356).

Based on this evidence in humans and animals, OSHA preliminarily concludes that exposure to dinitrobenzene potentially causes eye and respiratory tract irritation, anoxia, anemia, and liver damage. The Agency preliminarily finds that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. OSHA believes that establishing an 8-hour TWA PEL of 1 mg/m3, and a skin notation, for dinitrobenzene in agriculture is necessary to significantly reduce these risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

DINITROTOLUENE (ALL ISOMERS) CAS: 25321-14-6; Chemical Formula: CH₃C₆H₅(NO₂)₂ H.S. No. 2072

In general industry, construction, and maritime, OSHA's permissible exposure limit for dinitrotoluene is 1.5 mg/m3 as an 8-hour TWA, with a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. There is no limit in agriculture. The ACGIH has an 8-hour TLV -TWA of 1.5 mg/m3, and a skin notation, for dinitrotoluene. The NIOSH REL for this substance is the lowest feasible level; however, NIOSH concurs (Ex. 8-47, Table N6A) with the limit being proposed. OSHA is proposing an 8-hour TWA limit of 1.5 mg/m3, and a skin notation, for dinitrotoluene in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

The commercial grade of dinitrotoluene is a mixture of the orthometa- and para-isomers and is an oily liquid; the pure isomers are yellow crystals. Dinitrotoluene is used in the manufacture of explosives and dyes and in organic synthesis (ACGIH 1986, p. 216; Hawley's 1987, p. 422).

Dinitrotoluene causes methemoglobinemia, anemia, and liver damage in humans and animals. In

animals, dinitrotoluene has also caused liver tumors and reproductive effects. The oral LDses in rats, mice, and guinea pigs are 268 mg/kg, 790 mg/kg, and 1300 mg/kg, respectively (RTECS 1990). Cats tolerated repeated doses of 2 or 4 ml of 1 percent dinitrotoluene in cod liver oil up to a total of 24 ml and showed no signs of toxic effects (Kuhls 1905, in ACGIH 1986, p. 216). When administered cutaneously at a dose of 0.3 g/kg, cats showed no signs of toxic effects, but cats given two doses of 5 g died in 8 hours (Zieger 1913, in ACGIH 1986, p. 216). After oral treatment at unspecified doses for 5 days, male rats showed significantly elevated cytochrome P-450dependent enzyme activities (Dent and Graichen 1982, in HSDB 1988). Hepatotoxic effects have also been observed in dogs, mice, and rats orally exposed to dinitrotoluene (NIOSH CIB 44 1985). In rats (130/sex/group) administered dietary doses of 3.5 or 14 mg/kg/day, a decrease in mean body weight and a high incidence of hepatic neoplasms and hepatotoxicity were observed, in addition to an increased incidence of mammary fibroadenomas and subcutaneous sarcomas (Chemical **Industry Institute of Toxicology Report** 1982, in HSDB 1988). Oral administration of dinitrotoluene caused reproductive effects, such as testicular and ovarian atrophy, decreased fertility, and decreased sperm count among rats, mice, and dogs (NIOSH CIB 44 1985). Block et al. (1988) evaluated the effects of 2,4-dinitrotoluene on the rat testis. Adult Sprague-Dawley rats were fed diets containing 0.1 or 0.2 percent dinitrotoluene for 3 weeks. Among rats fed the higher dose, the authors reported finding marked changes in sertpli cell morphology, including swollen mitochondria and distended endoplasmic reticulum. In addition, reduced weights of the epididymides and decreased sperm reserves were observed. These results indicate that dinitrotoluene can induce testicular injury and interfere with late-stage spermatogenesis.

In humans, exposure to dinitrotoluene causes anemia, methemoglobinemia. and liver damage. The effects of methemoglobinemia may include headache, fatigue, nausea, vomiting. chest pain, and weight loss (Proctor, Hughes, and Fischman 1988, p. 218). At a methemoglobin concentration of 15 percent, cyanosis occurs, with blueness of the lips, nose, and earlobes as the first signs of overexposure to dinitrotoluene; at a methemoglobin level of 40 percent, there is weakness and dizziness; and at a 70-percent concentration, methemoglobinemia causes ataxia, dyspnea, tachycardia,

nausea, vomiting, and drowsiness (Hamblin 1963, in Proctor, Hughes, and Fischman 1988, p. 218). Ingestion of alcohol and high ambient temperatures can increase the toxic effects of dinitrotoluene exposure (von Oettingen 1941; Linch 1974, in Proctor, Hughes, and Fischman 1988, p. 218). Severe burns of the skin and eyes, with permanent scarring, were caused by hot fumes of dinitrotoluene (Smejkal 1949, in Grant 1986, p. 416). A workman employed in a dinitrotoluene production facility for a year developed tingling and numbness in the toes and legs; after 2 years, the symptoms became worse and vision decreased, but these disorders improved within a year after the cessation of exposure (Hamilton and Nixon 1918, in Grant 1986, p. 416). Chronic exposure to dinitrotoluene has been reported to cause jaundice and anemia (Clayton and Clayton 1982, p. 2483). A medical survey conducted in Kentucky where workers were exposed to dinitrotoluene and toluenediamine revealed a significant reduction in sperm count among males, suggesting that these substances may adversely affect the male reproductive system (Ahrenholz 1980, in HSDB 1988).

Based on this evidence in humans and animals, OSHA preliminarily concludes that dinitrotoluene causes methemoglobinemia, anemia, and liver injury. OSHA preliminarily finds that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that establishing a permissible exposure limit of 1.5 mg/m3 as an 8-hour TWA for dinitrotoluene is necessary to significantly reduce the risks of these material health impairments. In addition, promulgation of this PEL for dinitrotoluene will make the PEL for this substance consistent across all OSHAregulated sectors.

DIPROPYL KETONE CAS: 123–19–3; Chemical Formula:

(CH₃CH₂CH₂)₂CO H.S. No. 1148

OSHA has no limit for dipropyl ketone in construction, maritime, or agriculture. The ACGIH has a TLV* of 50 ppm TWA for this substance. NIOSH has no REL. In construction, maritime, and agriculture, OSHA is proposing a PEL of 50 ppm as an 8-hour TWA, and NIOSH concurs (Ex. 8-47, Table N1) with this limit. This is the limit recently established for this substance in general industry.

Dipropyl ketone is a colorless liquid with a pleasant odor. It finds use as a solvent for nitrocellulose, raw and blown oils, resins, and polymers. It is also used in lacquers and flavorings

(Hawley's 1987, p. 431).

Dipropyl ketone has a moderate oral and inhalation toxicity. In rats, the oral LD50 is 3.35 g/kg, and the dermal LD50 in rabbits is 9.5 g/kg. Tests have indicated that rats inhaling 2000 ppm for 4 hours survived, but at 4000 ppm all animals died (Carpenter, Weil, and Smyth 1974/ Ex. 1-304). Methyl isobutyl ketone (MIBK) has a similar acute toxicity (ACGIH 1986/Ex. 1-3, p. 221); OSHA is establishing a 50 ppm 8-hour TWA and

a 75 ppm STEL for MIBK.

OSHA is proposing to establish an 8hour TWA PEL of 50 ppm TWA for dipropyl ketone in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit is necessary to protect workers in these sectors from the significant risk of narcosis and irritation, both material health impairments that are associated with exposure to dipropyl ketone. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

CAS: 85-00-7; Chemical Formula: C12H12Br2N2

H.S. No. 1150

OSHA has no PEL for diquat in construction, maritime, or agriculture. The ACGIH has a TLV®-TWA of 0.5 mg/m3 for this substance. The proposed PEL is 0.5 mg/m3 as an 8-hour TWA, and NIOSH concurs (Ex. 8-47, Table N1) with this limit. OSHA is proposing this limit for diquat in the construction, maritime, and agriculture industries. This is the limit recently established for this substance in general industry.

Diquat is a yellow crystalline solid that is used as a herbicide and as a plant growth regulator (Hawley's 1987, p. 431). When used in pesticidal applications and in accordance with directions on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide

In most species, the acute oral toxicity of diquat is similar to that of paraquat; the LD₅₀ for diquat ranges from 100 to 400 mg/kg in rats, mice, rabbits, and dogs. The 24-hour percutaneous LD50 in rabbits is greater than 400 mg/kg; no skin irritation or other ill effects were demonstrated at this level (Clark and Hurst 1970/Ex. 1-135; Rowe and Wright 1965, as cited in ACGIH 1986/Ex. 1-3, p. 222). Rats fed 1000 ppm of diquat daily (about 50 mg/kg/day) for two years survived; reduced food intake and growth were the only consequences observed. At 500 ppm (about 25 mg/kg/ day), the only ill effect observed was a pathologic change in the eye. A dietary

level of 10 ppm (about 0.5 mg/kg/day) for 2 years did not induce cataract formation, but cataracts do occur at higher levels, with pathology observed at 500 ppm; one in four animals demonstrated complete corneal opacity in one or both lenses after 6 months at the 1000-ppm level. Cataract formation requires prolonged exposure and is not induced by single high-level exposures (ACGIH 1986/Ex. 1-3, p. 222).

Unlike paraquat, diquat does not produce lung damage in exposed humans or animals. Acute poisoning may produce nonspecific respiratory distress as well as other nonspecific signs of poisoning. In humans, accidental ingestion has produced less toxic reactions than those associated with paraquat ingestion (Orepoulos and

McEvoy 1969/Ex. 1-429).

In construction, maritime, and agriculture, OSHA is proposing an 8hour TWA PEL of 0.5 mg/m3 TWA for diquat. The Agency preliminarily concludes that this limit will protect workers in these sectors from the significant risk of ocular damage, which constitutes a material health impairment that is associated with chronic exposure to diquat. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

DISULFOTON CAS: 298-04-4; Chemical Formula:

C₈H₁₉O₂PS₃ H.S. No. 1152

OSHA has no exposure limit for disulfoton in construction, maritime, or agriculture. The ACGIH has a TLV®-TWA of 0.1 mg/m3 for this substance. There is no NIOSH REL. The proposed PEL for disulfoton in construction, maritime, and agriculture is 0.1 mg/m3 as an 8-hour TWA, with a skin notation. This is the limit recently established for this substance in general industry.

Pure disulfoton is an oily, colorless liquid; the technical grade is a brown liquid. This substance is a systemic insecticide and acaricide (Hawley's 1987, p. 435). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

The acute toxicity of disulfoton is very high by all laboratory-tested routes of administration. For weanling rats, the intraperitoneal LD50 is reported to be 5.4 mg/kg; for adult rats, it is 9.4 mg/kg (Brodeur and Dubois 1963/Ex. 1-718). The acute dermal LD50 is 6 mg/kg for adult female rats and 25 mg/kg for adult male rats (Gaines 1969/Ex. 1-320). The acute oral LD50s for male and female rats are reported as 6.8 mg/kg and 2.3

mg/kg, respectively (Brodeur and Dubois 1964/Ex. 1-1015). Rats have demonstrated an acquired tolerance for disulfoton (Brodeur and Dubois 1964/Ex.

Metabolically, disulfoton is highly fatsoluble, and the compound apparently interferes with mixed-function oxidase activity in the same manner shown to be the case for parathion; with respect to median lethal doses, parathion and disulfoton are similar (Stevens et al. 1973, as cited in ACGIH 1986/Ex. 1-3, p. 226).

OSHA is proposing an 8-hour TWA PEL for disulfoton of 0.1 mg/m3, with a skin notation, in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will prevent the significant risk of acute toxicity and metabolic injury, which are material impairments of health that are associated with exposure to this substance. The skin notation is included to protect workers in these sectors against the dermal toxicity that has been demonstrated in animal tests. Promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

DIVINYL BENZENE CAS: 108-57-6; Chemical Formula: C6H4(CHCH2)2 H.S. No. 1154

OSHA has no limit for divinvl benzene in construction, maritime, or agriculture. The ACGIH has a TLV®-TWA of 10 ppm, based on this substance's similarity to styrene. There is no NIOSH REL. In construction, maritime, and agriculture, OSHA is proposing an 8-hour TWA PEL of 10 ppm. NIOSH concurs (Ex. 8-47, Table N1) with this limit, which was recently established for this substance in general industry.

The commercial grade of divinyl benzene is a pale-straw-colored liquid; it contains all three isomers, but the meta isomer predominates. This substance is used as a polymerization monomer for various materials (Hawley's 1987, p.

The oral LD50 in rats is reported to be 4.1 g/kg, and an acute inhalation study showed no ill effects from a single 7hour exposure at 351 ppm. However, repeated or prolonged contact with the liquid may cause skin burns (Dow Chemical Company 1977j, as cited in ACGIH 1986/Ex. 1-3, p. 228).

Industrial experience indicates that irritation of the respiratory system, skin, and eyes can result from inhalation exposures to divinyl benzene, but there are no data concerning chronic exposures in humans.

OSHA is proposing a PEL of 10 ppm (8-hour TWA) for divinyl benzene in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risk of irritation to the respiratory tract, eyes, and skin; such irritation constitutes a material impairment of health within the meaning of the Act. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. **ENDOSULFAN** CAS: 115-29-7; Chemical Formula: CoHsCloO3S

OSHA has no permissible exposure limit for endosulfan in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 0.1 mg/m³, with a skin notation. There is no NIOSH REL. The proposed PEL is 0.1 mg/m³ as an 8-hour TWA, with a skin notation; NIOSH concurs (Ex. 8-47, Table N1) with this limit. This is the limit recently established for this substance in general industry.

H.S. No. 1156

Technical endosulfan is a tan, semiwaxy solid mixture; it may have a slight odor similar to that of sulfur dioxide. This substance is used as an insecticide (Hawley's 1987, p. 462). When used in pesticidal applications and in accordance with directions on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Endosulfan is similar in its acute oral toxicity to the related insecticides aldrin and dieldrin (TLV*-TWAs of 0.25 mg/ m³), except that it is slightly more toxic than these substances in female laboratory animals. In rats, the oral LD50 for endosulfan is 43 mg/kg for males and 18 mg/kg for females (Farm Chemicals Handbook 1974/Ex. 1-1147a). The dermal LDsos in male and female rats are 130 mg/kg and 74 mg/kg, respectively (Farm Chemicals Handbook 1974/Ex. 1147a). The respiratory LC50 for male rats is 50 mg/ kg for 4 hours of exposure (Association of American Pesticide Control Officials, Inc. 1969, as cited in ACGIH 1986/Ex. 1-3, p. 230).

In laboratory tests of chronic exposure, rats tolerated oral doses of up to 3.2 mg/kg/day for 3 months without injury (Gaines 1975, as cited in ACGIH 1986/Ex. 1–3, p. 230), and dogs tolerated doses up to 0.75 mg/kg for 1 year (Ely, MacFarlane, Galen, and Hines 1967/Ex. 1–414). A 2-year dietary level at 10 ppm (approximately 0.5 mg/kg/day) in rats was associated with a statistically insignificant decline in female survival rates and a reduction in testis weights in

males. At 5.0 mg/kg/day, histopathologic findings showed renal tubular damage and some hydropic changes in rat livers (Czech 1958, as cited in ACGIH 1986/Ex. 1-3, p. 230).

Inhalation of endosulfan dust by humans has been associated with slight nausea, confusion, excitement, flushing, and dry mouth (State of California, Department of Industrial Relations/Ex. 1–8). Nine employees who had been working with 50-percent water-wettable endosulfan powder for only a few days had convulsions (Association of American Pesticide Control Officials, Inc. 1969, as cited in ACGIH 1986/Ex. 1–3, p. 230).

OSHA preliminarily concludes that exposure to endosulfan poses a significant risk of systemic poisoning and renal and testicular damage, and the Agency therefore is proposing a PEL of 0.1 mg/m3 TWA for endosulfan in construction, maritime, and agriculture. with a skin notation; these effects constitute material impairments of health within the meaning of the Act. OSHA preliminarily finds that this limit will substantially reduce the significant risk associated with exposure to this substance at the levels permitted by the absence of a limit. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. EPN (Ethyl-p-

nitrophenylthionobenzenephosphate) CAS: 2104-64-5; Chemical Formula:

C₁₄H₁₄NO₄PS H.S. No. 2074

In general industry, construction, and maritime, OSHA's permissible exposure limit for EPN is 0.5 mg/m3 as an 8-hour TWA; this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. There is no limit in agriculture. The ACGIH has an 8-hour TLV*-TWA of 0.5 mg/m3, with a skin notation, for EPN. The limit for EPN was set based on analogy with parathion, which appears to be about five times more toxic than EPN but causes similar effects (ACGIH 1986, p. 234). NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing to establish an 8-hour TWA PEL of 0.5 mg/ m³, with a skin notation, for EPN in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated

EPN is a light yellow solid or brown crystalline substance. It is used as an acaricide and as an insecticide in cotton insect pest control (ACGIH 1986, p. 234; Hawley's 1987, p. 466). When used in pesticidal applications and in accordance with directions on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

EPN is an anticholinesterase agent and neurotoxin in humans and animals. The oral LD50 in rats is 7 mg/kg; in dogs. it is 20 mg/kg (RTECS 1990). Dermal LDsos in rats and rabbits are 25 mg/kg and 30 mg/kg, respectively (RTECS 1990). Administration of a single dermal dose of 22.5 to 225 mg/kg or of 0.5 to 2.0 mg/kg/day for 90 days caused delayed neurotoxicity in cats; these animals developed leg weakness and ataxia. At autopsy, histological changes were seen in the central and peripheral nervous systems of subchronically exposed animals (Abou-Donia 1983). Although a dietary level of 50 ppm for 1 year (equivalent to 210 mg/person/day) caused no observable effects in rats, 180 ppm (equivalent to 630 mg/person/day) caused damage to the adrenal cortex tissue within 52 weeks (Lehman 1952, in ACGIH 1986, p. 234). In a study in which rats were maintained on a dietary EPN level of 25 ppm for 13 weeks, some cholinesterase inhibition was observed; the same results were seen in rats given 5 ppm (0.24 mg/kg/day) or more for 13 weeks (DuBois et al. 1986; Suzuki 1973. in Hayes 1982, p. 410).

In humans, ingestion, inhalation, or dermal absorption of EPN produces signs and symptoms of anorexia. nausea, vomiting, abdominal cramps, diarrhea, chest tightness, wheezing, bronchial secretions, excessive salivation, cyanosis, slurred speech, confusion, convulsions, and coma (Proctor, Hughes, and Fischman 1988, p. 226). A 73-year-old man who ingested a dose of EPN estimated to be about 1429 mg/kg showed typical signs of anticholinesterase poisoning, including muscle spasms and coma; the patient died after 14 days (Hosaka and Yamaura 1976, in Hayes 1982, pp. 410-411). In studies with volunteers who ingested EPN doses beginning at 3 mg/ person/day, the toxicity threshold appeared to be 9 mg/person/day (≈0.13 mg/kg/day) (Rider et al. 1959; Moeller and Rider 1959, 1962a, in Hayes 1982, p. 410). Ten volunteers ingested 6 mg/ person/day of EPN for 47 days without observable effects on their cholinesterase activity (Rider et al. 1959; Moeller and Rider 1959, 1962a, in Hayes 1982, p. 410). An accidental release of EPN at a manufacturing facility caused muscle weakness and cerebellar effects in exposed workers (Froines 1979, in NIOSH Testimony on Neurotoxic Chemicals).

Based on this evidence in humans and animals, OSHA preliminarily concludes that exposure to EPN causes cholinesterase inhibition. OSHA preliminarily finds that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that establishing a PEL of 0.5 mg/m3 as an 8-hour TWA, and a skin notation, for EPN in agriculture is necessary to substantially reduce these risks of material health impairment. In addition, establishing this limit for EPN in agriculture will make OSHA's PEL for this substance consistent across all OSHA-regulated sectors.

FONOFOS CAS: 944-22-9; Chemical Formula: C₁₀H₁₅OPS₂ H.S. No. 1181

OSHA has no limit for fonofos in the construction, maritime, or agriculture industry. The ACGIH has a TLV*-TWA of 0.1 mg/m³, with a skin notation, for this substance. There is no NIOSH REL. The proposed PEL is an 8-hour TWA of 0.1 mg/m³, with a skin notation; NIOSH concurs (Ex. 8-47, Table N1) with this limit. This is the limit recently established for this substance in general industry.

Fonofos is a light-yellow liquid (ACGIH 1986, p. 275). This substance is used as a soil insecticide (Hawley's 1987, p. 449). When used in pesticidal applications and in accordance with directions on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide

Act (FIFRA).

In male rats, the average acute oral LD50 of technical fonofos has been reported to be 13.2 mg/kg (Stauffer Chemical Co. 1974, as cited in ACGIH 1986/Ex. 1-3, p. 275). For female rats, an average oral LDso of 3 mg/kg has been reported (NIOSH 1974d). The acute dermal LD50s reported for rats and guinea pigs are 147 and 278 mg/kg, respectively (Weir and Hazleton 1981/ Ex. 1-1135). Weir and Hazleton reported that no localized eye irritation occurred when 0.1 ml of technical fonofos was instilled into rabbit eyes; however, death resulted in these animals within 24 hours after the instillation (1981/ Ex.1-1135). Dietary studies in rats lasting 105 weeks have shown 10 ppm (about 0.2 mg/kg) to be a no-effect level. Dogs fed fonofos for 14 weeks showed no-effect dietary levels of 8 ppm; no carcinogenic effects were observed. Rats showed reproductive effects at dietary levels of 10 ppm and 31.6 ppm (about 0.7 mg/kg) (Stauffer Chemical Co. 1974, as cited in ACGIH 1986/Ex. 1-3, p. 275).

There are no reports of human poisonings caused by fonofos, although it is known to be a cholinesterase inhibitor (ACGIH 1986/Ex. 1-3, p. 275).

OSHA is proposing an 8-hour PEL of 0.1 mg/m3 TWA for fonofos to protect exposed workers in construction, maritime, and agriculture from the significant risk of cholinesterase inhibition that is characteristic of exposure to this and other organophosphate pesticides. OSHA considers cholinesterase inhibition a material impairment of health. A skin notation is also proposed, based on evidence in animals that fonofos can readily penetrate the skin and cause death. The Agency preliminarily concludes that this limit will substantially reduce this significant risk. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. FORMAMIDE

CAS: 75-12-7; Chemical Formula: CH₅NO

H.S. No. 1182

OSHA's limit for formamide in the construction and maritime industries is 20 ppm as an 8-hour TWA. The ACGIH has a TLV*-TWA of 20 ppm and a TLV*-STEL of 30 ppm for this substance. There is no NIOSH REL. OSHA is proposing PELs of 20 ppm as an 8-hour TWA and 30 ppm as a 15-minute STEL for formamide in construction, maritime, and agriculture. These are the limits recently established for this substance in general industry.

Formamide is a colorless, oily liquid that is odorless (ACGIH 1986, p. 278.5). This substance is used as a solvent, a softener, and a chemical intermediate

(Hawley's 1987, p. 537).

Formamide has an LD50 of approximately 6 g/kg for rats (Thiersh 1962/Ex. 1-690; Zaeva, Vinogradova, Savina, and Osipenko 1969/Ex. 1-1026). Dietary administration at 1.5 g/kg for 2 weeks resulted in fatalities in rats; pathologic examination revealed cumulative changes characteristic of gastritis and malnutrition (E.I. du Pont de Nemours and Company, Inc., as cited in ACGIH 1986/Ex. 1-3, p. 278). Czajkowska (1981, as cited in ACGIH 1986/Ex. 1-3, p. 278) reports the dermal LDo for skin absorption in rabbits as 6 g/kg. Eye, mucous membrane, and skin irritation occur on exposure to this substance (Sax and Lewis 1989, p. 1766). Eye irritation tests in rabbits showed only slight, temporary irritation (Carpenter and Smyth 1946/Ex. 1-303). No signs of toxicity were detected in rats in single 6-hour exposures at 3900 ppm formamide dispensed as a mist, or in 6-hour daily exposures for 10 days at

approximately 1500 ppm formamide vapor (equivalent to air saturated with formamide at room temperature); no indications of organ damage were seen in these animals on pathologic examination (E.I. du Pont de Nemours and Company, Inc., as cited in ACGIH 1986/Ex. 1–3, p. 278).

Gross fetal malformations were not noted following dermal applications of formamide to the skin of pregnant rats; the effects that were observed were weak and were produced at overwhelming concentrations (Stula and Krauss 1977/Ex. 1–1068). The no-observed-effect level in a rabbit developmental toxicity study was 22 mg/kg orally (Merkle and Zeller 1980/Ex. 1–683).

According to the ACGIH, there are no reports of industrial poisoning by formamide (E.I. du Pont de Nemours and Company, Inc., as cited in ACGIH 1986/Ex. 1-3, p. 278).

In the prior rulemaking, NIOSH pointed out (Ex. 8-47, Table N2) that formamide is a testicular toxin and has been identified as a teratogen in mice. OSHA is aware of the developing literature on both formamide and dimethyl formamide; however, the primary objective of the present rulemaking is to make OSHA's limits consistent across all regulated sectors. At the present time, OSHA is proposing a PEL of 20 ppm TWA and a STEL of 30 ppm for formamide in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risks of eye and skin irritation as well as other health effects associated with occupational exposure to formamide at levels above the proposed PELs. OSHA considers sensory irritation, testicular toxicity, and teratogenicity material impairments of health within the meaning of the Act. Promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors. At the time of the first PEL update, OSHA will review the literature on the toxicity of formamide to determine whether a further reduction in the PEL is necessary.

GERMANIUM TETRAHYDRIDE CAS: 7782-65-2; Chemical Formula: GeH₄ H.S. No. 1186

OSHA has no limit for germanium tetrahydride in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 0.2 ppm for this substance. There is no NIOSH REL. The proposed PEL is an 8-hour TWA of 0.2 ppm, with which NIOSH concurs (Ex. 8-47, Table

N1). OSHA is proposing this limit for germanium tetrahydride in the construction, maritime, and agriculture industries. This is the limit recently established for this substance in general industry.

Germanium tetrahydride is a colorless gas. This substance is used in the electronics industry (ACGIH 1986, p.

284).

An early study indicated that germanium tetrahydride has a toxicity between that of tin hydride and arsine (Flury and Zernik 1931e/Ex. 1-993). In this study, a rabbit survived exposure to 100 ppm for one hour. One-hour exposures at 150 and 185 ppm caused fatalities in mice, and similar exposures involving guinea pigs resulted in sickness at the 150-ppm level and death at 185 ppm (Flury and Zernik 1931e/Ex. 1-993). On the other hand, Webster (1946/Ex. 1-399) reported that germanium tetrahydride is less toxic than both tin hydride and arsine. The effect of exposure to germanium tetrahydride is hemolysis. Data concerning chronic or subacute toxicities are not available. Based on germanium's acute toxicity, which is approximately half that of stibine, the ACGIH recommends an 8-hour TLV® of 0.2 ppm TWA.

In construction, maritime, and agriculture, OSHA is proposing a PEL of 0.2 ppm as an 8-hour TWA for germanium tetrahydride to reduce the significant risk of hemolytic effects, which constitute material impairments of health that are associated with occupational exposure to this substance. The Agency preliminarily concludes that implementation of this limit will substantially reduce this significant risk for workers in these sectors. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

INDENE

CAS: 95-13-6; Chemical Formula: C₉H₈ H.S. No. 1212

OSHA's current limit for indene in the construction and maritime industries is 10 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 10 ppm for this substance. The proposed PEL for indene in construction, maritime, and agriculture is 10 ppm as an 8-hour TWA, a limit with which NIOSH concurs (Ex. 8-47, Table N1). This is the limit recently established for indene in general industry.

Indene is a colorless liquid. This substance is used as a chemical intermediate (Hawley's 1987, p. 634).

Early inhalation studies of indene reported injury to the spleen, liver, and

kidneys of rats exposed to indene vapor concentrations of 800 to 900 ppm for six 7-hour periods (Cameron and Doniger 1939/Ex. 1-470). Some animals were found at necropsy to have severe necrosis of the liver with hemorrhage; kidney necrosis was also observed. No other organ damage was found and no deaths occurred as a result of these exposures (Cameron and Doniger 1939/ Ex. 1-470). By analogy with the effects of exposure to other monoaromatic hydrocarbons, exposure to indene is likely to irritate the mucous membranes. In laboratory animals, chemical pneumonitis, pulmonary edema, and hemorrhage have resulted from the aspiration of indene liquid into the lung, and repeated skin contact has caused dermatitis as a result of the defatting properties of indene (Gerarde 1960b/Ex. 1-738b). In dermal studies of rats, one to eight applications of 0.1 ml to the shaved skin were reported to have no effect; three applications of 0.5 ml to guinea pig skin also produced no effect (Cameron and Doniger 1939/Ex. 1-470). The oral toxicity of indene appears to be moderate, with adult rabbits tolerating a single dose of 1 gram without signs of systemic toxicity (Gerarde 1960b/Ex. 1-738b). Subcutaneous injection of 1 gram, however, caused liver pathology and fatalities; high oral doses (2.5 ml of a 1:1 v/v mixture in olive oil) were uniformly fatal, with characteristic liver, lung, and gastrointestinal changes. Chronic administration of 3 mg/m3 indene for 105 days caused catalase inhibition and stimulation of blood cholinesterase in rats, but no effects were observed in rats exposed at 0.6 mg/m³ (Dyshinevich 1976/Ex. 1-631).

OSHA is proposing to establish an 8-hour TWA PEL of 10 ppm for indene in construction, maritime, and agriculture. OSHA preliminarily concludes that this limit will reduce the significant risks of irritation, pulmonary effects, and systemic toxicity, which constitute material impairments of health that are associated with occupational exposure to this substance. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. IODOFORM

CAS: 75-47-8; Chemical Formula: CHI₃ H.S. No. 1214

OSHA has no limit for iodoform in construction, maritime, or agriculture. The ACGIH has an 8-hour TLV*-TWA limit of 0.6 ppm for this substance. The proposed PEL for iodoform in construction, maritime, and agriculture is 0.6 ppm as an 8-hour TWA; NIOSH concurs (Ex. 8-47, Table N1) with this limit, which is identical to the PEL

recently established for this substance in general industry.

Iodoform is a yellow-green solid with a penetrating odor. It is used in medicine as an external antiseptic (Hawley's 1987, p. 643).

The subcutaneous LD50 for rabbits is 50 mg/kg, and the oral LDLo for iodoform in dogs is 1000 mg/kg (Kutob and Plaa 1962/Ex. 1-61). These authors also report that, on a molar basis, iodoform has an acute toxicity in mice similar to that of methyl iodide; this conclusion is based on parameters of lethality, barbiturate sleeping time, and bromsulphalein (BSP) retention time. An NCI bioassay (1978c/Ex. 1-1117) of iodoform indicates that the substance is not carcinogenic nor of high systemic toxicity, although histopathological examination of laboratory animals in this bioassay was judged by NCI to be inadequate.

No human data are available for this compound.

OSHA is proposing an 8-hour TWA limit of 0.6 ppm for iodoform; OSHA preliminarily concludes that this limit will protect workers in construction, maritime, and agriculture from the significant risks of irritation and hepatotoxicity, both material impairments of health that are associated with exposure to iodoform. The Agency has preliminarily determined that this limit will substantially reduce these significant risks for workers in these sectors. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

ISOBUTYL ACETATE
CAS: 110–19–0; Chemical Formula:
CH₃COOCH₂CH(CH₃)₂
H.S. No. 2097

In general industry, construction, and maritime, OSHA currently has an 8-hour TWA limit of 150 ppm for isobutyl acetate. The Agency has no PEL for this substance in agriculture. The 1987-1988 ACGIH TLV*-TWA for isobutyl acetate was 150 ppm as an 8-hour TWA and 187 ppm as a STEL. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the PEL being proposed for this substance. OSHA is proposing an 8-hour TWA PEL of 150 ppm for isobutyl acetate in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Isobutyl acetate is a colorless liquid with a fruity odor similar to that of the acetate esters. Isobutyl acetate is used in thinners, sealants, and topcoat lacquers. It is also used as a solvent for nitrocellulose, as a flavoring agent in

beverages, and in the manufacture of perfume (ACGIH 1986, p. 330; Genium MSDS 1990, No. 396).

Isobutyl acetate causes skin, eye, and mucous membrane irritation and, at high concentrations, this substance causes central nervous system depression in humans and animals (Proctor, Hughes, and Fischman 1988, p. 289; NIOSH/ OSHA Occupational Health Guideline 1981, p. 1). This substance appears to be more acutely toxic than n-butyl acetate but less irritating to the eyes, mucous membranes, and skin than the n-isomer (ACCIH 1986, p. 330). The oral LDsos in rats and rabbits are 13,400 mg/kg and 4763 mg/kg, respectively (RTECS 1990). The lowest lethal concentration in rats is 8000 ppm for 4 hours; no deaths occurred in rats exposed to 4000 ppm (Smyth et al. 1962, in Proctor, Hughes, and Fischman 1988, p. 289; RTECS 1990). Rabbits showed moderate skin irritation when 500 mg of isobutyl acetate was left on their skin for 24 hours; moderate eye irritation was observed when the same dose was instilled into rabbit eves (RTECS 1990). Exposure to 21,000 ppm of isobutyl acetate for 150 minutes caused narcosis and death in six of six rats exposed; no symptoms were observed at a concentration of 3000 ppm for 6 hours (Clayton and Clayton 1981, p. 2273).

In humans, exposure to isobutyl acetate causes mild irritation of the eyes and mucous membranes; at high but unspecified concentrations, this substance causes central nervous system depression (HSDB 1985). The acute symptoms of central nervous system depression include headache, muscle weakness, confusion, giddiness, and delirium (Genium MSDS 1990, No. 396). The onset of isobutyl acetateinduced narcosis is gradual, and recovery after the cessation of exposure is likely to be slow (Clayton and Clayton 1982, p. 2268). Liquid isobutyl acetate defats the skin, and repeated contact causes irritation and may lead to dermatitis (Genium MSDS 19890, No.

Based on this evidence in humans and animals, OSHA preliminarily concludes that isobutyl acetate is a skin, eye, and mucous membrane irritant and, at high concentrations, a narcotic. The Agency concludes that, in the absence of a limit for this substance, workers in agriculture are at significant risk of experiencing these effects, which constitute material impairments of health. OSHA believes that the proposed 8-hour TWA PEL of 150 ppm will substantially reduce these significant risks. In addition, promulgation of this limit will make

OSHA's PEL for this substance consistent across all regulated sectors. ISOBUTYL ALCOHOL CAS: 78-83-1; Chemical Formula: [CH₃]₂CHCH₂OH

H.S. No. 1219

In construction and maritime, OSHA currently has a limit of 100 ppm as an 8-hour TWA for isobutyl alcohol. There is no limit in agriculture. The ACGIH has a limit of 50 ppm TLV*-TWA for this substance. In construction, maritime, and agriculture, OSHA is proposing 50 ppm as an 8-hour TWA; NIOSH concurs (Ex. 8-47, Table N1) with this limit. This is the limit recently established for this substance in general industry.

Isobutyl alcohol is a colorless liquid that is used as a solvent, in organic synthesis, and as an ingredient in a wide variety of consumer products (Hawley's 1987, p. 653).

Limited inhalation studies have reported a somewhat higher acute toxicity for isobutyl alcohol than for nbutyl alcohol (which has a ceiling of 50 ppm) (Smyth, Carpenter, and Weil 1951/ Ex. 1-439; Smyth, Carpenter, Weil, and Pozzani 1954/Ex. 1-440). A 4-hour LC50 of 8000 ppm has been reported for isobutyl alcohol in rats. Ingestion studies in rabbits have reported an acute oral toxicity of 3.75 g/kg for isobutyl alcohol (Smyth, Carpenter, and Weil 1951/Ex. 1-439; Smyth, Carpenter, Weil, and Pozzani 1954/Ex. 1-440). The dermal LD50 is 4.2 g/kg (Stokinger 1976, as cited in ACGIH 1986/Ex. 1-3, p. 331). Weese (1928/Ex. 1-1073) reported that the narcotic inhalation dose over a total of 136 hours is 6400 ppm in mice. Slight changes in the liver and kidneys were reported at autopsy, but no fatalities occurred after repeated narcotizing doses (Weese 1928/Ex. 1-1073).

The effects of liquid isobutyl alcohol on the human eye appear to be comparable to those of n-butanol; no data are available on ocular exposure to the isobutyl alcohol vapor. Dermal application of isobutyl alcohol has caused slight erythema and hyperemia in humans (Schwartz and Tulipan 1939/Ex. 1–1167; Oettel 1936/Ex. 1–921).

OSHA is proposing to reduce the 8-hour TWA PEL for isobutyl alcohol of 100 ppm to 50 ppm in construction and maritime and also proposes a 50-ppm limit in agriculture. The Agency preliminarily concludes that a 50-ppm limit will reduce the significant risk of skin irritation, which is a material impairment of health that is associated with exposure to concentrations at levels above the revised PEL. Promulgation of this limit will also make OSHA's PEL for this substance consistent across all regulated sectors.

ISOOCTYL ALCOHOL

CAS: 26952–21–6; Chemical Formula:

CH₃(CH₂)₃CH(C₂H₅)CH₂OH

H.S. No. 1220

OSHA has no PEL for isooctyl alcohol in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 50 ppm, with a skin notation, for this substance. The proposed PEL is 50 ppm as an 8-hour TWA, with a skin notation, for isooctyl alcohol in construction, maritime, and agriculture. NIOSH concurs (Ex. 8-47, Table N1) with this limit, which was recently established for this substance in general industry.

Isooctyl alcohol is a clear, combustible liquid. It finds use as an ingredient in plasticizers, an intermediate for nonionic detergents and surfactants, and as an ingredient in a variety of oils and fluids (Hawley's 1967, p. 658).

The single-dose oral LDzos for isooctyl alcohol reported for rats and mice are between 3.2 and 6.4 g/kg; intraperitoneal injection LD50s for these species range from less than 0.4 g/kg to 1.6 g/kg (Hodge 1943/Ex. 1-700; Fassett 1951, as cited in ACGIH 1986/Ex. 1-3, p. 332). The dermal LD50 for the guinea pig is greater than 10 ml/kg (Fassett 1951, as cited in ACGIH 1986/Ex. 1-3, p. 332); in the rabbit, the dermal LD50 is 2.38 ml/kg (Smyth, Carpenter, Weil et al. 1969/Ex. 1-442). Moderate skin irritation from exposure to isooctyl alcohol has also been reported. Rats and rabbits have shown skin irritation at exposure levels ranging from 1.7 to 3.34 ml/kg (Smyth, Carpenter, Weil, et al. 1969/Ex. 1-442). Passett (1951, as cited in ACGIH 1986/ Ex. 1-3, p. 332) also reported no fatalities in rats after an 8-hour inhalation test at 235 ppm.

OSHA is proposing to establish an 8-hour TWA PEL of 50 ppm, with a skin notation, for isooctyl alcohol in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will reduce the significant risks of skin irritation, a material impairment of health that is associated with exposure to this substance at levels above the new PEL. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. N-ISOPROPYLANILINE

CAS: 768-52-5; Chemical Formula: C₆H₆NHCH(CH₅)₂ H.S. No. 1229

OSHA has no limit for Nisopropylaniline in construction, maritime, or agriculture. The ACGIH recommends a TLV®-TWA of 2 ppm, with a skin notation, for this substance. There is no NIOSH REL for this substance. OSHA is proposing an 8-hour TWA PEL of 2 ppm, with a skin notation, for this substance in construction, maritime, and agriculture; NIOSH concurs (Ex. 8-47, Table N1) with the proposed limit. This is the limit recently established for this substance in general industry.

N-Isopropylaniline is a yellowish, combustible liquid that is used as an intermediate and fiber dye (Hawley's

1987, p. 661)

The oral LDso for rats exposed to Nisopropylaniline is between 0.25 and 0.5 g/kg. Slight irritation of the skin and eyes has been reported in animals as a result of direct contact with this chemical (Dow Chemical Company 1977k, as cited in ACGIH 1986/Ex. 1-3. p. 338). No other data concerning chronic toxicity or human exposure are available (ACGIH 1986/Ex. 1-3, p. 338).

Chemical analysis shows Nisopropylaniline to have toxicologic properties similar to those of its parent compound, aniline. The oral LD508 for the two chemicals are approximately equal. OSHA has established a 2-ppm 8hour TWA PEL for N-isopropylaniline on the basis of its structural analogy with aniline (which has the same PEL) and N,N-dimethylaniline (which has a 5ppm 8-hour TWA PEL and a 10-ppm 15minute STEL); exposure to these substances has been shown to cause hemolytic and central nervous system effects in animals and humans. These substances are also toxic when absorbed through the skin.

OSHA is proposing an 8-hour PEL of 2 ppm for N-isopropylaniline, with a skin notation, in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors from the significant risk of irritation and systemic and hemolytic effects, all material health impairments that are caused by inhalation, ingestion, or dermal absorption of N-isopropylaniline. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

CAS: 463-51-4; Chemical Formula: CH2=C=0

H.S. No. 1231

OSHA's 8-hour TWA limit for ketene in construction and maritime is 0.5 ppm. There is no limit in agriculture. The ACCIH has a TLV*-TWA of 0.5 ppm and a TLV®-STEL of 1.5 ppm for this substance. There is no NIOSH REL. In construction and maritime, OSHA is retaining the 8-hour TWA and proposing to add a 15-minute STEL of 1.5 ppm; the Agency is also proposing to extend both limits to agriculture. NIOSH concurs (Ex. 8-47, Table N-1) with the proposed limits, which are those recently established for this substance in general industry.

Ketene is a colorless gas with a sharp, penetrating odor. Ketene is used as an acetylating agent and as a starting point in the production of products such as acetic anhydride and acetate esters (ACGIH 1986, p. 341; Hawley's 1987, p.

Ketene is highly irritating to the respiratory tract [Mendenhall and Stokinger 1959/Ex. 1-428), and the effects of its action are delayed (Treon, Sigmon, Kitzmiller 1949/Ex. 1-769). Mendenhall and Stokinger (1959/Ex. 1-428) have reported a 10-minute LCso for mice of 17 ppm. Chronic exposure to 1 ppm for six months on a schedule of 6 hours/day, 5 days/week, was tolerated by animals of several species (Mendenhall and Stokinger 1960, as cited in ACGIH 1986/Ex. 1-3, p. 341). Similar results have been reported in monkeys exposed repeatedly (55 exposures) for seven hours at each exposure (Treon, Sigmon, and Kitzmiller 1949/Ex. 1-769). Evidence strongly suggests that the development of emphysema and fibrosis may occur in individuals who have developed a tolerance to the acute effects of ketene exposure (Stokinger, Wagner, and Dobrogarski 1957/Ex. 1-139).

In construction and maritime, OSHA is retaining the 8-hour TWA PEL of 0.5 ppm and proposing to add a 15-minute STEL of 1.5 ppm for ketene; OSHA is also proposing to extend both limits to agriculture. The Agency preliminarily concludes that workers exposed to this highly irritating and toxic gas are at significant risk of developing respiratory irritation, pulmonary edema, and other severe pulmonary effects that constitute material health impairments. OSHA preliminarily finds that both a TWA and STEL are required to protect workers in construction, maritime, and agriculture from ketene's acute and chronic health effects. The proposed limits are necessary to substantially reduce these risks. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all

regulated sectors.

METHACRYLIC ACID CAS: 79-41-4; Chemical Formula: $CH_2 = C(CH_3)COOH$

H.S. No. 1244

OSHA has no limit for methacrylic acid in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 20 ppm for this substance. There is no NIOSH REL. OSHA is proposing an 8-hour TWA PEL of 20 ppm for methacrylic acid in construction,

maritime, and agriculture, and NIOSH concurs (Ex. 8-47, Table N1) that this limit is appropriate. This is the limit recently established for this substance in general industry.

Methacrylic acid is a liquid with an acrid, disagreeable odor. Metacrylic acid is used as a monomer for large volume resins and polymers and in organic synthesis (ACGIH 1988, p. 362;

Hawley's 1987, p. 751).

The primary toxic hazard associated with exposure to methacrylic acid is irritation, although the degree of irritation from exposure to this substance is significantly less than that from exposure to acrylic acid (ACGIH 1986/Ex. 1-3, p. 362). Direct contact of methacrylic acid with the skin or eye can cause corrosion of the skin or blindness. In rabbits, the skin absorption LD50 for methacrylic acid is 0.5 to 1g/kg (Dow Chemical Company 1977m, as cited in ACGIH 1986/Ex. 1-3. p. 362). Rats exposed by inhalation to approximately 1000 ppm of methacrylic acid exhibited eye irritation (Dow Chemical Company 1977m, as cited in ACGIH 1986/Ex. 1-3, p. 362). Rats exposed to a 300 ppm concentration of this substance for 6 hours daily for 20 days showed slight congestion of the kidneys at autopsy (Gage 1970/ Ex. 1-

Medical reports of workers exposed acutely to concentrations of up to 113 ppm methacrylic acid in an industrial setting revealed that these workers experienced no respiratory symptoms; however, skin responses and a severe corneal burn were reported (Dow Chemical Company 1977m, as cited in ACGIH 1986/Ex. 1-3, p. 362).

OSHA is proposing a PEL of 20 ppm as an 8-hour TWA for methacrylic acid. with a skin notation, in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors from the significant risk of severe eye and skin irritation, which are material health impairments that are associated with occupational exposure to methacrylic acid. The skin notation is necessary to prevent dermal absorption and systemic toxicity. Promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

4-METHOXYPHENOL CAS: 150-76-5; Chemical Formula: CH4OC6H4OH H.S. No. 1247

OSHA has no limit for 4methoxyphenol in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 5 mg/m3 for this

substance. There is no NIOSH REL, but NIOSH concurs with the proposed limit (Ex. 8-47, Table N1). In construction, maritime, and agriculture, OSHA is proposing a PEL of 5mg/m³; this is the limit recently established for this substance in general industry.

4-methoxyphenol is a white, waxy solid used in the manufacture of antioxidants, pharmaceuticals, plasticizers, and dyestuffs. 4-methoxyphenol is also used as a stabilizer for chlorinated hydrocarbons, as an inhibitor for acrylic monomers and acrylonitriles, and as a UV inhibitor (ACGIH 1986, p. 367; Hawley's 1987, p. 620).

In rats, the oral LD₅₀ for 4-methoxyphenol is between 1 and 2 g/kg; the skin absorption LD₅₀ in rabbits is greater than 1 g/kg. Results of a two-month dietary study demonstrated no ill effects at 0.1 ppm (approximately 50 mg/kg/day). Direct contact of 4-methoxyphenol with the skin or eyes causes burns or moderate corneal damage (Hodge, Sterner, Maynard, and Thomas 1949/Ex. 1–41; Dow Chemical Company 1977n, as cited in ACGIH 1986/Ex. 1–3, p. 367).

To reduce the risk of dermal and ocular effects resulting from exposure to 4-methoxyphenol, a compound similar in chemical structure and toxicity to hydroquinone, OSHA is proposing to establish a permissible exposure limit in construction, maritime, and agriculture of 5 mg/m3 as an 8-hour TWA. The Agency preliminarily concludes that this limit is necessary to protect workers in these sectors against the significant risk of dermal and skin effects potentially associated with exposure to this substance. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

METHYL ACETYLENE-PROPADIENE MIXTURE (MAPP)

CAS: None; Chemical Formula: C₃H₄ isomers

H.S. No. 1250

OSHA has a PEL of 1000 ppm as an 8-hour TWA for MAPP in construction and maritime. There is no limit in agriculture. The ACGIH also has an 8-hour TLV*-TWA limit of 1000 ppm and a TLV*-STEL of 1250 ppm for this substance. There is no NIOSH REL. OSHA is retaining the 8-hour PEL of 1000 ppm, proposing to add a STEL of 1250 ppm for this substance in construction and maritime, and proposing to extend both limits to agriculture. NIOSH concurs (Ex. 8-47, Table N1) with the limits being proposed, which were recently

established for MAPP in general industry.

MAPP contains 58 percent of a mixture of propadiene (a colorless, unstable gas with a strong, unpleasant odor) and methyl acetylene (a colorless gas with a sweet odor); the balance of the mixture consists of paraffinic and olefinic C₃ and C₄ hydrocarbons. Methyl acetylene-propadiene mixture is used as an industrial fuel for cutting, welding, brazing, heat treating, and metallizing (Hawley's 1987, p. 756).

Rabbits, dogs, and guinea pigs exposed to an average MAPP concentration of 5000 ppm for 7 hours/day, 5 days/week for 4 months showed no exposure-related effects except decreased lung weights at autopsy. No changes were observed in animals exposed to 1000 ppm on this regimen for four months (Dow Chemical Company 1964, as cited in ACGIH 1986/Ex. 1–3, p. 368)

On the basis of these data, which show MAPP to be a chemical mixture of low toxicity in experimental animals, the Agency is retaining its 8-hour TWA PEL of 1000 ppm and proposing to add a STEL of 1250 ppm in construction and maritime, and is also proposing to extend both limits to agriculture. The Agency preliminarily concludes that both of these limits are necessary to ensure that workers in these sectors are protected and that good industrial hygiene practice is maintained. In addition, promulgation of these limits will make OSHA's PELs for MAPP consistent across all regulated sectors.

METHYLAL (Dimethoxymethane) CAS: 109-87-5; Chemical Formula: CH₃OCH₂PCJ₃

H.S. No. 2108

The OSHA PEL for methylal in general industry, construction, and maritime is 1000 ppm as an 8-hour TWA. There is no limit for methylal in agriculture. The ACGIH has a TLV*-TWA of 1000 ppm for this substance. NIOSH has no REL for methylal, but concurs (Ex. 8-47, Table N1) with the PEL being proposed. OSHA is proposing a PEL of 1000 ppm as an 8-hour TWA for methylal in agriculture. Promulgation of this limit will make the PEL for methylal consistent across all OSHA-regulated sectors.

Methylal is a colorless, volatile, flammable liquid with a chloroform-like odor (Hawley's 1987, p. 756). Methylal is used as a specialized fuel, as a solvent in perfumes, adhesives, and coatings, and as a reaction medium for the Grignard and Reppe reactions in organic synthesis (Merck 1983, p. 864; ACGIH 1986, p. 371).

Methylal is an irritant of the eves and mucous membranes and, at high concentrations, a central nervous system depressant in both humans and animals. The oral LDso in rabbits is 5708 mg/kg; the LC50 in rats is 15,000 ppm for an unspecified period (RTECS 1987; Weaver et al. 1951, in Clayton and Clayton 1982, p. 2657). Exposure to a concentration of approximately 154,000 ppm methylal caused tearing of the eyes, sneezing, nasal discharge, coughing, and vomiting in guinea pigs; these animals became comatose in 20 minutes and died within 2.5 hours (Weaver et al. 1951, in Proctor, Hughes, and Fischman 1988, p. 319). In mice exposed to 15 daily 7-hour inhalation exposures to 11,000 ppm, minor irritation of the eyes and nose occurred and incoordination developed after 3 or 4 hours of exposure. Mice exposed to a 14,000-ppm concentration of methylal exhibited a greater degree of irritation and anesthesia (Weaver et al. 1951, in Clayton and Clayton 1982, p. 2657). Autopsy of guinea pigs exposed to very high but unspecified concentrations of methylal revealed moderate to severe fatty degeneration of the liver and kidneys, as well as extensive bronchopneumonia; however, no significant histopathological changes were noted in guinea pigs exposed for five daily 7-hour exposures to a 45,000ppm concentration of methylal. Although methylal vapor is irritating to the eyes of experimental animals, no histological abnormalities of the optic nerve or retina have been reported (Weaver et al. 1951, in Clayton and Clayton 1982, p. 2657; Grant 1986, p. 606). In humans, methylal causes eye, mucous membrane, skin, and upper respiratory tract irritation; at high concentrations, central nervous system depression is observed. Methylal was formerly used as an anesthetic in human medicine; however, this use has been discontinued because the anesthetic effect of methylai is slower and more transitory than that of ether (Weaver et al. 1951, in Proctor, Hughes, and Fischman 1988, p. 319). Methylal has a defatting effect on the skin, and frequent or prolonged contact causes dermatitis (Proctor, Hughes, and Fischman 1988, p. 320).

Based on this evidence, OSHA is proposing a 1000 ppm 8-hour TWA limit to protect workers in agriculture from the significant risk of central nervous system depression caused by exposure to higher concentrations of methylal. The Agency preliminarily concludes that this limit is necessary to substantially reduce a significant risk of material health impairment. In addition, promulgation of this limit will make

OSHA's PEL for this substance consistent across all regulated sectors METHYLAMINE CAS: 74-89-5; Chemical Formula:

CH₂NH₂ H.S. No. 2110

OSHA's PEL for methylamine in general industry, construction, and maritime is 10 ppm as an 8-hour TWA. There is no PEL for methylamine in agriculture. The ACGIH has a TLV*-TWA of 10 ppm for this substance. NIOSH has no REL for methylamine but concurs with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 10 ppm for methylamine in agriculture. Promulgation of this limit will make the PEL for methylamine consistent across all OSHA-regulated sectors.

Methylamine is a colorless, flammable gas with a fishy odor at low concentrations and an ammonia-like odor at high concentrations (Braker and Mossman 1980, p. 498). Methylamine is used as a chemical intermediate for accelerators, dyes, insecticides, fungicides, pharmaceuticals, and surface-active agents. It is also used as a fuel additive, a polymerization inhibitor, a solvent, a rocket propellant, a photographic developer, and a component of some paint removers

(HSDB 1988). Methylamine is an irritant of the eyes. mucous membranes, and respiratory tract in both humans and animals. Administered orally as the base in a 40 percent aqueous solution, the LD50 for rats is 0.1 to 0.2 g/k g; the LCso in mice is 2400 mg/m3 for 2 hours (Clayton and Clayton 1982, p. 3148; RTECS 1987). Ocular damage, including hemorrhages of the conjunctiva, shallow corneal opacities, and edema have resulted from the administration of a single drop of 5 percent methylamine in water into the eyes of experimental animals (Grant 1986, p. 606). Corneal damage occurred in rabbit eyes after contact with a 40percent methylamine solution, and necrosis of the skin developed in rabbits whose skin had been wetted with 0.1 milliliter of the same solution (Smyth and Carpenter 1944. In contact with liquefied methylamine, guinea pig skin swelled and turned purple after a few minutes. The skin turned gray and necrotic after 48 hours; fresh granulation tissue covered by flat epidermis, with no hair follicles, appeared 12 days after the exposure (Goffman and Maguire 1980, in HSDB 1988).

Human toxicity data for methylamine are limited. A chemical worker exposed to methylamine at concentrations ranging from 2 to 60 ppm for an unspecified period of time developed allergic or chemical bronchitis (ACGIH 1986, p. 373). Transient eye, nose, and throat irritation occurs when humans are exposed for brief periods to concentrations ranging from 20 to 100 ppm, although exposures to methylamine concentrations below 10 ppm do not cause irritation. Severe exposure to methylamine would be expected to cause pulmonary edema. Prolonged or repeated exposure of the skin or eyes causes dermatitis or inflammation of the conjunctiva, respectively (Proctor, Hughes, and Fischman 1988, p. 321).

Based on this evidence, OSHA is proposing a 10 ppm 8-hour TWA PEL to protect workers in agriculture from the significant risk of eye, nose, and respiratory tract irritation caused by exposure to methylamine. The Agency preliminarily concludes that this limit is necessary to substantially reduce a significant risk of material health impairment in exposed workers. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

METHYL DEMETON

CAS: 8022-00-2; Chemical Formula: (CH₂O)₂PSO(CH₂)₂SC₂H5 H.S. No. 1258

OSHA has no limit for methyl demeton in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 0.5 mg/m³, with a skin notation. There is no NIOSH REL, but NIOSH concurs (Ex. &-47, Table N1) with the proposed limit. OSHA is proposing an 8-hour TWA of 0.5 mg/m³, and a skin notation, for methyl demeton in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry.

Methyl demeton is an oily, colorless to pale-yellow liquid with an unpleasant odor. Methyl demeton is used as a systemic insecticide and acaricide [ACGIH 1986, p. 388; Hawley's 1987, p. 766]. When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Methyl demeton has an oral LD₅₀ of 40 to 65 mg/kg for the thiolo-isomer and 150 to 250 mg/kg for the thiono-isomer. Both isomers form sulfoxide or sulfone, with an oral LD₅₀ similar to that of the parent compounds (Dubois and Plzak 1962/Ex. 1–629; Heath and Vandekar 1965, Klimmer and Plaff 1955, both as cited in ACGIH 1986/Ex. 1–3, p. 388). In solution or storage, methyl demeton may form alkyl sulfonium compounds that have very high intravenous toxicity and oral LD₅₀s of 10 to 20 mg/kg. Dermal toxicity is reported to be moderate, with

an LD₅₀ of approximately 400 mg/kg (Heath and Vandekar 1965, as cited in ACGIH 1986/Ex. 1–3, p. 388).

In humans, methyl demeton causes changes in intraocular pressure, and acute poisonings produce nausea, headache, dizziness, vomiting, and hyperemia of the nasal mucosa. Chronic exposure causes hyperemia of the respiratory organs and irritation of the inner ear (Dugel'nyy 1970; Rasuleva 1970, both as cited in ACGIH 1986/Ex. 1–3, p. 388).

OSHA is proposing an 8-hour TWA PEL for methyl demeton of 0.5 mg/m3. with a skin notation, in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in this sectors from the significant risk of ocular and nasal irritation, pulmonary effects, and cholinesterase inhibition, all of which constitute material impairments of health that are associated with occupational exposure to this substance. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

METHYLENE BISPHENYL ISOCYANATE (MDI) CAS: 101–68–8; Chemical Formula: CH₂(C₆H₄NCO)₂ H.S. No. 2109

OSHA's permissible exposure limit (PEL) for methylene bisphenyl isocyanate in general industry. construction, and maritime is 0.02 ppm (0.2 mg/m3) as a ceiling limit. There is no limit for this substance in agriculture. The ACGIH has assigned methylene bisphenyl isocyanate a TLV®-TWA of 0.005 ppm (0.050 mg/m3) (ACGIH 1989, p. 30). NIOSH has recommended exposure limits of 50 µg/m3 (0.005 ppm) as a 10-hour TWA and 200 µg/m3 (0.02 ppm) as a 10-minute ceiling limit for methylene bisphenyl isocyanate (NIOSH Recommendations 1988); however, NIOSH concurs with the limit being proposed by OSHA (Ex. 8-47, Table N1). OSHA is proposing a PEL of 0.02 ppm (0.2 mg/m3) as a ceiling limit for methylene bisphenyl isocyanate in agriculture. Promulgation of the proposed limit will make the PEL for this substance consistent across all OSHAregulated sectors.

Methylene bisphenyl isocyanate is an odorless white to light-yellow solid (ACGIH 1986, p. 389(86)). Methylene bisphenyl isocyanate is used in the production of polyurethane foams and plastics. It is also used in coating systems for aircraft, tank trucks, automobiles, and truck trailers (Proctor,

Hughes, and Fischman 1988, p. 330; IARC 1979, Vol. 19, p. 317).

In both humans and animals, methylene bisphenyl isocyanate is an irritant of the skin, eyes, and mucous membranes; it is also a respiratory and skin sensitizer. The 4-hour LC50s in rats are 36.2 ppm (males) and 37.3 ppm (females) (NIOSH 1978). By oral administration, methylene bisphenyl isocyanate is of low toxicity: the oral LD50 in rats is greater than 10 g/kg, and rats given oral doses of 5 g/kg/day methylene bisphenyl isocyanate for 5 days survived (Woolrich 1982). Undiluted methylene bisphenyl isocyanate applied to the skin of rabbits caused mild irritation that cleared within 5 days, and the application of 1 mg of a 10-percent methylene bisphenyl isocyanate solution to rabbit eyes produced mild inflammation and tearing but no permanent injury (Woolrich 1982). Administered to guinea pigs by intradermal injection, to mice by skin painting, or to dogs by intrabronchial instillation, methylene bisphenyl isocyanate elicits an immune sensitization response that is characterized by the development of antibodies specific to methylene bisphenyl isocyanate-serum albumin conjugate (Chang and Karol 1984; Thorne, Yeske, and Karol 1987).

Acute exposure to a concentration of 0.001 to 0.026 ppm methylene bisphenyl isocvanate caused eve, nose, and throat irritation in 34 of 35 exposed individuals and shortness of breath in 17 members of the exposed group (NIOSH 1978). Humans exposed to the vapors of methylene bisphenyl isocyanate may develop pulmonary irritation (characterized by increased lung and respiratory tract secretions, coughing, pain on breathing, and, if overexposure is severe, a reduction in breathing rate) and/or allergic sensitization (characterized by cold- or hayfever-like symptoms and asthma, hives, atopic eczema, and allergic reactions) (Woolrich 1982). Estimates of the percentage of occupationally exposed individuals likely to develop sensitization reactions to this substance range from 2 to 20 percent. Workers sensitized to methylene bisphenyl isocyanate are also likely to develop cross-reactivities to other isocyanates, such as toluene diisocyanate or hexamethylene diisocyanate (Woolrich 1982). For example, 12 of 25 individuals sensitized to toluene diisocyanate showed marked declines in lung function when exposed to a methylene bisphenyl isocyanate concentration of 0.009 to 0.02 ppm for 15 to 60 minutes (Innocenti et al. 1988). Exposure to

airborne methylene bisphenyl isocyanate concentrations below 0.1 ppm may cause sensitization in susceptible workers, while exposure to concentrations between 0.1 and 1.0 ppm may cause respiratory tract and mucous membrane irritation in all exposed individuals (Woolrich 1982). Workers exposed to both methylene bisphenyl isocvanate and toluene diisocvanate for at least 1 year at concentrations that occasionally exceeded 0.8 ppm had decrements in pulmonary function and an increased frequency of bronchitis compared with non-exposed workers; however, workers exposed to average methylene bisphenyl isocyanate and toluene diisocyanate concentrations of less than 0.003 ppm for 5 years showed no decrement in pulmonary function (Banks, Butcher, and Salvaggio 1986; Musk et al. 1982). Workers who have become sensitized to methylene bisphenyl isocyanate develop either an acute asthma-like response or sensitization pneumonitis when subsequently exposed to this substance; the asthmatic attacks may occur immediately or have a delayed onset, and the pneumonitis is characterized by fever, an increased white blood cell count, an increase in the number of neutrophils observed in bronchoalveolar lavage fluid, and an increase in breathing resistance (Genium MSDS 1980, No. 1105). Workers whose skin has been exposed repeatedly to methylene bisphenyl isocyanate may develop contact eczema (Rothe 1976, in ACGIH 1986, p. 390(86)).

Based on this evidence in humans and animals, OSHA preliminarily concludes that methylene bisphenyl isocyanate causes irritation and both skin and pulmonary sensitization. OSHA preliminarily finds that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these effects. OSHA believes that establishing a PEL of 0.02 ppm (0.2 mg/m3) as a ceiling limit is necessary to substantially reduce these risks of material health impairments. Promulgation of this limit will also make the PEL for methylene bisphenyl isocyanate consistent across all regulated sectors.

METHYL ETHYL KETONE PEROXIDE CAS: 1338-23-4; Chemical Formula:

C8H18O6 H.S. No. 1257

OSHA has no limit in construction, maritime, or agriculture for methyl ethyl ketone peroxide (MEKP). The ACGIH has a TLV*-ceiling of 0.2 ppm for this substance. There is no NIOSH REL. OSHA is proposing a ceiling limit of 0.7 ppm for this substance in construction, maritime, and agriculture. NIOSH

concurs (Ex. 8-47, Table N1) with this limit, which was recently established for this substance in general industry.

MEKP is sold commercially as a colorless liquid mixture consisting of approximately 60 percent MEKP and 40 percent diluent; the diluent is added to reduce MEKP's sensitivity to shock. Methyl ethyl ketone peroxide is used in the manufacture of acrylic resins and as a hardening agent for fiber glass reinforced plastics (Hawley's 1987, p. 769). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

The health effects data for MEKP in animals rely primarily on a study conducted in 1958 by Floyd and Stokinger (Ex. 1-783). In a series of experiments conducted in rats, mice, and rabbits to determine the toxicity of MEKP by various routes of exposure, these investigators found that inhalation exposure for 4 hours to a concentration of 200 ppm was fatal to 50 percent of rats, and a 4-hour exposure to 170 ppm was fatal to 50 percent of mice. Inhalation of MEKP vapors produced petechial and gross hemorrhages of the lungs in rats after four-hour exposures; liver and kidney damage was also observed (Floyd and Stokinger 1958/Ex. 1-783). Two drops of a 40-percent solution of MEKP in dimethyl phthalate caused severe damage when instilled in rabbits' eyes, but at 3 percent, a moderate, transient reaction was produced. The direct application of MEKP to closely shaved rabbit skin caused no immediate discomfort but did cause a severe delayed reaction, consisting of erythema, edema, and vesiculation within 2 or 3 days; of the four organic peroxides tested (di-t-butyl peroxide, t-butyl hydroperoxide, cumene hydroperoxide, and methyl ethyl ketone peroxide). MEKP exhibited the greatest toxicity. The maximal nonirritating strength of MEKP applied dermally was 0.6 percent. In addition, rats died or showed marked evidence of cumulative systemic effects after either oral or intraperitoneal administration of MEKP at 20 percent of the LD50 level for 3 days/week for 7 weeks (Floyd and Stokinger 1958/Ex. 1-783). The study of MEKP's toxicity performed by Floyd and Stokinger (1958/Ex. 1-783) was a thorough and comprehensive bioassay involving three species (mice, rats, and rabbits) and five routes of exposure (inhalation, intraperitoneal, oral, dermal, and eye contact). This study demonstrated that MEKP was 20- to 50fold more acutely toxic than di-t-butyl peroxide by all routes tested. The

consequences of exposure to this substance ranged from skin and eye irritation to gross hemorrhage of the lung and liver and kidney damage; OSHA notes that these effects were observed even after short-term exposures. The Floyd and Stokinger study (1958/Ex. 1-783) demonstrated that MEKP is significantly more toxic than benzoyl peroxide (PEL of 5 mg/m3) and resembles hydrogen peroxide (PEL of 1.4 mg/m3) in terms of its potential to cause irritation on an acute basis. A study by Moskowitz and Grabois (1950, as cited in ACGIH 1986/Ex. 1-3, p. 54) showed that exposure to 12.2 mg/ms benzoyl peroxide caused "pronounced irritation of the nose and throat" in workers; because MEKP is significantly more irritant than benzoyl peroxide, MEKP concentrations considerably below the 12 mg/m3 level can be expected to cause irritation as well.

OSHA has preliminarily concluded that the available data support the proposed ceiling PEL for MEKP 0.7 ppm. Because MEKP is more irritating than benzoyl peroxide and irritation can result from even very brief exposures to excessive concentrations of MEKP, OSHA also preliminarily concludes that a ceiling limit for MEKP is necessary and appropriate. Therefore, to reduce the significant risk of irritation to workers in construction, maritime, and agriculture who are exposed to MEKP, OSHA is proposing a 0.7 ppm ceiling PEL for MEKP in these sectors. Promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. METHYL FORMATE

CAS: 107-31-3; Chemical Formula: HCOOCH₃ H.S. No. 1258

OSHA has a limit of 100 ppm TWA as an 8-hour for methyl formate in construction and maritime. There is no limit in agriculture. The ACGIH also has an 8-hour TLV*-TWA of 100 ppm, with a TLV*-STEL of 150 ppm. OSHA is retaining the 8-hour TWA of 100 ppm for methyl formate and proposing to add a STEL of 150 ppm for this substance in construction and maritime; OSHA is also proposing both limits in agriculture. NIOSH concurs (Ex. 8-47, Table N1) that these limits, which were recently established for methyl formate in general industry, are appropriate.

Methyl formate is a flammable, colorless liquid with an agreeable odor. Methyl formate is used as a fumigant and larvicide. It is also used in organic synthesis and as a cellulose acetate solvent (ACGIH 1986, p. 397; Hawley's 1987, p. 770). When used in pesticidal applications and as directed on the

label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Methyl formate causes nose and eye irritation, vomiting, incoordination, narcosis, and death in guinea pigs exposed to high concentrations (Schrenk, Yant, Chornyak, and Patty 1936/Ex. 1-756). Exposure to a 5-percent concentration of methyl formate was fatal in 20 to 30 minutes, a 1.5- to 2.5percent concentration was dangerous in 30 to 60 minutes, and a 0.5 percent concentration (5000 ppm) was considered the maximum concentration tolerable for a 60-minute period without serious consequences. Lehmann and Flury (1943b/Ex. 1-963) observed that inhalation of a 1.02 percent concentration of methyl formate for two to three hours caused pulmonary edema and death in cats; a concentration of 1600 ppm resulted in lung inflammation after one hour. Guinea pigs died when exposed by inhalation to a 2.5 percent concentration of methyl formate (Lehmann and Flury 1943b/Ex. 1-963).

In studies of methyl formate exposure in humans, von Oettingen (1959/Ex. 1–499) reported that workers exposed to unspecified concentrations showed temporary blindness, narcosis, mucous membrane irritation, and dyspnea. Fairhall (1957c/Ex. 1–1107) has reported that methyl formate is more irritating than either methyl or ethyl acetate.

OSHA is retaining the 8-hour PEL of 100 ppm TWA and proposing to add a STEL of 150 ppm for methyl formate in construction and maritime; the Agency is also proposing to extend both limits to agriculture. OSHA believes that these PELs will prevent the significant risks of irritation, narcotic effects, and pulmonary damage, all of which constitute material health impairments, confronting workers in these sectors who are exposed to methyl formate. The Agency preliminarily concludes that these limits will substantially reduce these significant risks. In addition, promulgation of these limits will make OSHA's PELs for methyl formate consistent across all regulated sectors. METHYL IODIDE

CAS: 74-88-4; Chemical Formula: CH₃I H.S. No. 1259

OSHA has an 8-hour TWA limit of 5 ppm, and a skin notation, for methyl iodide in construction and maritime operations. The ACGIH has a TLV*-TWA of 2 ppm, with a skin notation, for methyl iodide and classifies it as a suspected human carcinogen (A2). NIOSH recommends reducing exposure to this substance to the lowest feasible limit and also considers this chemical a potential human carcinogen. OSHA is

proposing an 8-hour TWA PEL of 2 ppm, with a skin notation, for methyl iodide in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry.

Methyl iodide is a colorless, sweetsmelling liquid that turns yellow, red, or brown when exposed to light and moisture. Methyl iodide is used in microscopy, organic synthesis, and in testing for pyridine (ACGIH 1986, p. 399(86); Hawley's 1987, p. 772).

Methyl iodide has an LD50 in rats of 150 to 200 mg/kg; liver damage was evident after these lethal exposures (Kutob and Plaa 1962/Ex. 1-61). A 15minute exposure to a concentration of 3800 ppm was fatal to rats (Chambers et al. 1950, as cited in ACGIH 1986/Ex. 1-3. p. 399), and Bachem (1927/Ex. 1-1013) has reported that methyl iodide is six times as toxic in mice as methyl bromide. Inhalation studies have shown eye irritation and depressed body weight in rats as a result of 14-week exposures to 30 and 60 ppm (Blank, Nair, Roloff, and Ribelin 1984/Ex. 1-619). The same authors observed fatalities in rats within four weeks of exposure to 143 ppm; 10 ppm was reported to be a noeffect level.

In industry, fatalities have occurred in chemical workers exposed to methyl iodide poisoning (Garland and Camps 1945/Ex. 1–1190; Appel, Galen, O'Brien, and Schoenfeldt 1975/Ex. 1–1076). However, the exposure levels associated with these fatal overexposures are not known (ACGIH 1986/Ex. 1–3, p. 399).

In tests of carcinogenicity, methyl iodide produced local sarcomas in rats injected subcutaneously and lung tumors in mice given intraperitoneal injections (Druckrey, Kruse, Preussman et al. 1970/Ex. 1–246; Poirier, Stoner, and Shimkin 1975/Ex. 1–686). These carcinogenic effects occurred at a dosage approximately equivalent to a daily 8-hour exposure to 20 or 25 ppm for an adult human (ACGIH 1986/Ex. 1–3, p. 399).

OSHA is proposing an 8-hour TWA limit of 2 ppm, and a skin notation, for methyl iodide in construction, maritime, and agriculture. The Agency preliminarily concludes that these limits will protect workers in these sectors from the significant risk of irritation and liver and kidney damage, which are material impairments of health associated with occupational exposure to methyl iodide. The skin notation is needed to prevent dermal absorption of toxic amounts of methyl iodide. Promulgation of this limit will also make OSHA's PEL for this substance consistent across all regulated sectors.

METHYL ISOAMYL KETONE
CAS: 110-12-3; Chemical Formula:
CH₃COCH(C₂H₆)₂
H.S. No. 1260

OSHA has a TWA-PEL of 100 ppm for methyl isoamyl ketone (MIAK) in construction and maritime. There is no limit in agriculture. The ACGIH has established an 8-hour TLV*-TWA of 50 ppm for MIAK, and this is also the REL recommended by NIOSH. OSHA is proposing a PEL of 50 ppm as an 8-hour TWA for this substance in construction, maritime, and agriculture, and NIOSH concurs with this limit (Ex. 8-47, Table N1). This is the PEL recently established for this substance in general industry.

Methyl isoamyl ketone is a colorless, clear liquid with a pleasant odor. Methyl isoamyl ketone is used as a solvent for cellulose esters, acrylics, and copolymers (ACGIH 1986, p. 400).

The oral LD₅₀ for methyl isoamyl ketone in rats is 3.2 g/kg (RTECS 1991). The lowest lethal concentration in rats is 4000 ppm for 4 hours (RTECS 1991). Instilled into the eyes of rabbits, MIAK caused corneal damage rated 2 on an ascending severity of 1 to 10 (Grant 1974, p. 1166). Experimental animals exposed to high (not further specified) concentrations of ketones including MIAK show emphysematous changes to the lungs and damage to the liver, kidneys, and brain at autopsy (HSDB 1991). The dermal LD₅₀ in rabbits is 10 g/kg (RTECS 1991).

No data relating exposure levels to specific effects in humans have been reported. However, the ACGIH (1986/Ex. 1-3, p. 400) believes that MIAK is likely to be more irritating and a more potent narcotic than is the case for methyl isobutyl ketone.

The NIOSH criteria document on the ketones (1978f) states that "because methyl isoamyl ketone contains one more carbon atom than does methyl isobutyl ketone, methyl [isoamyl] ketone might produce irritation and narcosis at concentrations at least as low as those at which methyl isobutyl ketone produces these effects" (NIOSH 1978f).

OSHA is proposing an 8-hour TWA limit of 50 ppm for methyl isoamyl ketone in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risk of narcotic and irritant effects, which constitute material health impairments that are associated with occupational exposure to MIAK. Promulgation of this limit will also make OSHA's PEL for this substance consistent across all regulated sectors.

METHYL ISOPROPYL KETONE CAS: 563-80-4; Chemical Formula: (CH₃)₂CHCOCH₃ H.S. No. 1262

OSHA has no limit for methyl isopropyl ketone (MIPK) in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 200 ppm. NIOSH has no REL. In construction, maritime, and agriculture, OSHA is proposing a PEL of 200 ppm as an 8-hour TWA; NIOSH concurs (Ex. 8-47, Table N1) with this limit. This is the PEL recently established for MIPK in general industry.

Methyl isopropyl ketone (also called 3-methyl-2-butanone) is a colorless, flammable liquid. This substance is used as a solvent for nitrocellulose lacquers

(ACGIH 1986, p. 405).

Animal studies have shown that MIPK has an acute toxicity somewhat greater than that of diethyl ketone and somewhat less than that of di-n-propyl ketone or methyl-n-propyl ketone (ACGIH 1986/Ex. 1–3, p. 405). The oral LD $_{50}$ in rats is 148 mg/kg, and the dermal LDse in rabbits is 6350 mg/kg (RTECS 1991). Rats exposed for four hours at a concentration of 5700 ppm died (NIOSH 1977i, Ex. 1-1182). In contact with the skin of rabbits, this substance caused a moderate degree of irritation (RTECS 1991). Instilled into rabbit eyes, it caused mild irritation (RTECS 1991). Humans exposed to unspecified concentrations of MIPK develop slight eye irritation and skin irritation that ranges from mild to moderate (Clayton and Clayton 1981, p. 4738).

OSHA is proposing a PEL of 200 ppm (8-hour TWA) for methyl isopropyl ketone in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risk of irritation, a material health impairment that is associated with exposure to this ketone at the uncontrolled levels possible in the absence of a PEL. Promulgation of this limit will also make OSHA's PEL for this substance consistent across all regulated sectors.

METHYL PARATHION CAS: 298–00–0; Chemical Formula:

C₆H₁₀NO₅PS H.S. No. 1265

OSHA has no limit for methyl parathion in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 0.2 mg/m³, with a skin notation, for methyl parathion, and NIOSH also recommends a TWA of 0.2 mg/m³. In construction, maritime, and agriculture, the proposed PEL is an 8-hour TWA limit of 0.2 mg/m³, with a skin notation; NIOSH concurs (Ex. 8-47, Table N1) with this limit, which is identical to the

PEL recently established for this substance in general industry.

Methyl parathion is a tan to brown liquid with a pungent odor like that of garlic. This substance is used as a nonsystemic insecticide, especially for Cotton (Hawley's 1987, p. 777; Hayes 1982, p. 339). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Methyl parathion is an acetylcholinesterase inhibitor, and excessive exposure can cause sweating, salivation, diarrhea, bradycardia, bronchoconstriction, muscle fasciculations, and coma. Methyl parathion's acute oral LD50 in male rats is almost identical to that of parathion (i.e., 10 to 25 mg/kg); in fema le rats, the LD50 is 24 mg/kg, or approximately onesixth that of parathion. By the dermal route, methyl parathion is much less toxic than parathion, with an LD50 of 67 mg/kg in rats of both sexes (Hayes 1963/Ex. 1-982). Erythrocyte cholinesterase activity was inhibited in dogs fed methyl parathion for 12 weeks at a rate corresponding to approximately 24 mg/day; inhibition of both plasma and erythrocyte cholinesterase activity occurred at doses of 70 mg/day, without accompanying illness (Williams, Fuyat, and Fitzhugh 1959/Ex. 1-810). Dogs fed 6 mg/day methyl parathion for 12 weeks showed no effects from such exposures (Williams, Fuyat, and Fitzhugh 1959/Ex. 1-810). Lifetime feeding studies of rats and mice fed diets containing methyl parathion concentrations of up to 40 ppm and up to 125 ppm, respectively, produced no evidence of cancer (NCI 1979a/Ex. 1-1116).

Plasma and erythrocyte cholinesterase levels did not differ by more than 20 percent in subjects exposed at 7, 7.5, 8, or 9 mg/man/day, compared with controls (Moeller and Rider 1963/Ex. 1-565). Tiess, Wegener, and Tamme (1982/Ex. 1-774) have reported a case of protracted methyl parathion poisoning resulting from both percutaneous and inhalation exposures; Dille and Smith (1964/Ex. 1-549) attribute the long-term neuropsychiatric illness of two pilots to exposure to methyl parathion and other cholinesterase-inhibiting agents. Chronic exposure to small doses of methyl parathion have not caused chromosomal effects (de Cassia Stocco, Becak, Gaeta, and Rabello-Gay 1982/Ex. 1-540).

In construction, maritime, and agriculture, OSHA is proposing a limit of 0.2 mg/m³ TWA for methyl parathion, with a skin notation. The Agency

preliminarily concludes that this limit will protect workers in these sectors against the significant risk of acetylcholinesterase inhibition, which constitutes a material impairment of health that is associated with workplace exposures to this substance. The skin notation will protect workers from the significant risk of systemic toxicity associated with percutaneous absorption of this substance. In addition, promulgation of this limit will make OSHA's PEL for methyl parathion consistent across all regulated sectors. METHYLCYCLOHEXANE CAS: 108-87-2; Chemical Formula: C7H14 H.S. 1268

OSHA has an 8-hour TWA limit of 500 ppm for methylcyclohexane in construction and maritime, and the ACGIH has a TLV*-TWA of 400 ppm for this substance. There is no OSHA limit in agriculture. NIOSH has no REL, but concurs (Ex. 8-47, Table N1) with the limit being proposed. The proposed PEL for this substance in construction, maritime, and agriculture is 400 ppm. This is the limit recently established for methylcyclohexane in general industry.

Methylcyclohexane is a colorless liquid that is used as a solvent for cellulose esters and in organic synthesis

(ACGIH 1986, p. 384).

Lehmann and Flury (1943e, as cited in ACGIH 1986/Ex. 1-3, p. 384) indicate that the acute toxicity of methylcyclohexane is greater than that of heptane but less than that of octane. Lazarew (1929/Ex. 1-1059) found that a 2-hour exposure to a concentration of 7500 to 10,000 ppm caused prostration in mice, and exposure to 10,000 to 12,500 ppm caused death. Treon, Crutchfield, and Kitzmiller (1943b/Ex. 1-394) reported that exposure to 1200 ppm had no effect in rabbits and that prolonged exposures to 370 ppm had no effect in monkeys. Methylcyclohexane's histologic effects in animals resemble those of cyclohexane; the liver and kidney are the sites affected (ACGIH 1986/Ex. 1-3, p. 384).

OSHA is proposing to establish an 8-hour TWA limit of 400 ppm for methylcyclohexane in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risk of irritation, a material health impairment that is associated with exposure to methylcyclohexane. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

MANGANESE TRICARBONYL (as Mn)

CAS: 12108-13-3; Chemical Formula: (CH₃)C₅H₅-Mn(CO)₅ H.S. No. 1271

OSHA has no limit for 2-methylcyclopentadienyl manganese tricarbonyl (MCT) in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 0.2 mg/m³, measured as manganese, with a skin notation.

There is no NIOSH REL. The proposed PEL for this substance in construction, maritime, and agriculture is 0.2 mg/m³ as an 8-hour TWA, with a skin notation. NIOSH concurs (Ex. 8-47, Table N1) with the proposed limit, which is identical to the PEL recently established for this substance in general industry.

MCT, also called Cl-2, is a dark orange liquid with a faintly pleasant odor; it is a complex organic compound containing about 25 percent manganese by weight. MCT is used as a gasoline

additive.

MCT is highly toxic in its concentrated form, causing adverse effects primarily on the central nervous system. It is somewhat irritating to the eyes, but skin contact does not produce irritation or sensitization; however, MCT is readily absorbed through the skin (ACGIH 1986/Ex. 1–3, p. 387). Animal studies indicate that MCT has a toxicity similar to that of tetraethyl lead and is highly toxic by all routes of exposure (U.S. Navy Smoke Abatement Additive, as cited in ACGIH 1986/Ex. 1–3, p. 387).

The single-dose oral LD₅₀ for rats is 23 or 39 mg/kg, depending on sex. The skin LD₅₀ for rabbits is 1692±145 mg/kg, and the 1-hour inhalation LC₅₀ for rats is about 350 mg/m³ (the Ethyl Corporation, as cited in ACGIH 1986/Ex. 1–3, p. 387). Toxic exposures by all routes produce rapidly appearing symptoms of mild excitement, hyperactivity, tremors, severe clonic spasms, weakness, respiratory distress, and occasional clonic convulsions, followed by terminal coma (U.S. Navy Smoke Abatement Additive, as cited in ACGIH 1986/Ex. 1–

3, p. 387).

Acute exposure causes damage to the liver, kidneys, and cerebral cortex, as well as changes in lung tissue (ACGIH 1986/Ex. 1-3, p. 387). Browning (1966/Ex. 1-1018) observed chronic bronchitis, peribronchitis, interstitial pneumonia, and lung abscesses in animals that subsequently died from long-term inhalation exposure to MCT; exposure to MCT concentrations of approximately 12 mg/m3 for 100 days produced no deviation in weight gain patterns and no gross or microscopic changes in two dogs (Browning 1966/Ex. 1-1018). The liver and kidneys are the principal target organs associated with acute

overexposures; at autopsy, the lungs of overexposed animals were hemorrhagic (Browning 1966/Ex. 1–1018).

In humans, skin contact with MCT should be entirely avoided. A 5- to 15-ml spill on one worker's hand and wrist was reported to have caused "thick tongue," nausea, giddiness, and headache within 3 to 5 minutes (U.S. Navy Smoke Abatement Additive, as cited in ACGIH 1986/Ex. 1–3, p. 387).

OSHA is proposing a PEL of 0.2 mg/ m3 TWA, measured as manganese, and a skin notation for 2methylcyclopentadienyl manganese tricarbonyl in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risk of CNS effects and systemic damage, which constitute material health impairments that are associated with occupational exposure to MCT. A skin notation is necessary because of MCT's demonstrated ability to penetrate human skin rapidly and to cause systemic effects. Promulgation of this limit will also make OSHA's PEL for this substance consistent across all regulated sectors.

MONOCROTOPHOS (AZODRIN) CAS: 6923–22–4; Chemical Formula: C₇H₁₄NO₅P H.S. No. 1279

OSHA has no limit for monocrotophos (also called Azodrin) in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 0.25 mg/m³ for this substance. There is no NIOSH REL. The proposed PEL is 0.25 mg/m³ as an 8-hour TWA for monocrotophos in construction, maritime, and agriculture. NIOSH concurs (Ex. 8–47, Table N1) with this limit, which was also recently established for this substance in general industry.

Monocrotophos is a reddish brown liquid with a mild ester odor. It is used as a systemic insecticide to control certain insects on cotton plants (ACGIH 1986, p. 416; Hawley's 1987, p. 110). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Monocrotophos is a highly toxic, direct acting cholinesterase inhibitor that penetrates the intact skin (ACGIH 1986/Ex. 1–3, p. 416). The acute oral LD₅₀ values in rats and mice range from 5.7 to 17 mg/kg in a water formulation (Brown et al. 1970, Shellenberger and Newell, both as cited in ACGIH 1986/Ex. 1–3, p. 416) and from 10 to 23 mg/kg in an oil formulation (Shellenberger and Newell,

as cited in ACGIH 1986/Ex. 1-3, p. 416). These authors also report a percutaneous LD50 in the rabbit that ranges from 112 to 709 mg/kg, depending on the vehicle used. A two-year dietary study of rats ingesting 0, 1, 10, or 100 ppm monocrotophos revealed that both sexes in the 100 ppm group failed to gain as much weight as the controls, but autopsy showed no significant findings; plasma, erythrocyte, and brain cholinesterase decreased at the two highest dose levels but were unaffected at 1 ppm (Johnston 1966-67, as cited in ACGIH 1986/Ex. 1-3, p. 416). Another two-year feeding study in dogs administered doses of up to 16 ppm monocrotophos revealed no adverse effects at levels of 0.16 and 1.6 ppm, but serious cholinesterase reduction was observed at the 16-ppm level (Johnston 1968-67, as cited in ACGIH 1986/Ex. 1-3, p. 416). Metabolism studies in rats and goats indicate that monocrotophos is excreted rapidly in the rat and does not accumulate in the body (Bull and Lindquist 1966/Ex 1-719); goats given labeled monocrotophos by mouth showed only traces of the material in their milk (Menzer and Casida 1965/Ex. 1-986; Potter, as cited in ACGIH 1986/ Ex. 1-3, p. 416). Inhalation exposure of rats to an unknown concentration of 75 percent monocrotophos in air for one hour was not lethal; a four-hour exposure to an unknown concentration of the aerosol (0.4 and 0.75 percent) was fatal to two out of six (0.4 percent aerosol) and five out of eight rats (0.75 percent aerosol). Head-only exposure to the 0.4-percent aerosol resulted in the death of one of eight animals (Wilson, as cited in ACGIH 1986/Ex. 1-3, p. 416).

Intravenous injection of radiolabeled monocrotophos in human volunteers showed maximum excretion at 4 to 8 hours, with 67±5 percent of the material in the urine; absorption of 14 ± 7 percent occurred when the radiolabeled material was applied to the forearm; 33±9 percent of the applied dose was absorbed when it was covered with a vapor-proof film for 72 hours (Maibach 1970, as cited in ACGIH 1986/Ex. 1-3, p. 416). Although gauze patches attached to the clothing and skin of field workers attested to the presence of monocrotophos, no cholinesterase inhibition was observed in postexposure examinations at 3 hours and at three and seven days (Maibach, as cited in ACGIH 1986/Ex. 1-3, p. 416).

OSHA is proposing a PEL of 0.25 mg/m³ (8-hour TWA) for monocrotophos in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risk of cholinesterase inhibition, a material

impairment of health that is associated with exposure to this substance in the workplace. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

MORPHOLINE

CAS: 110-91-8; Chemical Formula:

C₄H₉NO H.S. No. 1281

In construction and maritime, OSHA has a limit of 20 ppm, with a skin notation, for morpholine. There is no limit in agriculture. The ACGIH has a 20-ppm TLV*-TWA limit and a TLV*-STEL of 30 ppm, as well as a skin notation. There is no NIOSH REL. OSHA is retaining the 8-hour TWA PEL of 20 ppm, and the skin notation, in construction and maritime, is proposing to add a STEL of 30 ppm in these two sectors, and is also proposing both limits and the skin notation in agriculture. NIOSH concurs (Ex. 8-47, Table N1) that these limits are appropriate. These are the limits recently established for morpholine in general industry.

Morpholine is a colorless liquid with an amine-like odor. Morpholine is used as a rubber accelerator, a solvent, an additive to boiler water, a corrosion inhibitor, a preservative in book paper, and an organic intermediate (ACGIH 1986, p. 417(89); Hawley's 1987, p. 799).

Exposure to morpholine produces nasal and bronchial irritation and liver and kidney impairment in animals (Shea 1939/Ex. 1-758); the substance readily penetrates the skin and is highly irritating to the eyes (Jefferson Chemical Company, Inc. 1961, as cited in ACGIH 1986/Ex. 1-3, p. 417). The single oral LD50 in rats is 1.05 g/kg (range: 0.95 to 1.16 g/kg), and the single skin LD50 for 24-hour contact is 0.5 ml/kg (Smyth, Carpenter, Weil, and Pozzani 1954/Ex. 1-440). Neither a one-hour exposure to concentrated vapor nor an 8-hour exposure to 8000 ppm was fatal in rats (Smyth, Carpenter, Weil, and Pozzani 1954/Ex. 1-440). Rats were exposed for 8 hours daily to a concentration of 18,000 ppm for a total of 5 days; after the first day, all animals showed severely reddened thoracic walls, and one fatality (from kidney and liver congestion) occurred. A similar fatality occurred on the third day; on day 4, a third rat died, and postmortem examination revealed degeneration of the epithelial lining of the kidney tubules. Three additional deaths occurred after the exposures had ended; autopsy revealed thickened alveoli, emphysema, and liver and kidney effects (Shea 1939/Ex. 1-758).

Reporting on his own reactions to morpholine exposure at a concentration of 12,000 ppm, Shea (1939/Ex. 1–758) complained of nose irritation (after 1 minute) and coughing (after 90 seconds); in addition, when he transferred morpholine by pipette, he experienced sore throat and mucosal irritation. All symptoms disappeared after the experiment stopped (Shea 1939/Ex. 1-758). Skin contact poses a moderately high degree of hazard, which diminishes as the product is diluted with water to less than 25 percent (Jefferson Chemical Company, Inc. 1961, as cited in ACGIH 1986/Ex. 1-3, p. 417). Respiratory irritation but no chronic effects have been reported as a result of industrial exposure (Patty 1963e/Ex. 1-858). In comparison with ammonia, morpholine has a greater potential for systemic toxicity (ACGIH 1986/Ex. 1-3, p. 417).

OSHA is retaining the 8-hour TWA limit of 20 ppm TWA and the skin notation for morpholine and is proposing to add a 15-minute STEL of 30 ppm in construction and maritime: OSHA is also proposing both limits and the skin notation in agriculture. The Agency preliminarily concludes that these limits will work together to protect workers in these sectors against the significant risk of eye and respiratory tract irritation, which are material impairments of health that are associated with occupational exposures to this substance. The skin notation for morpholine is necessary because of this substance's ability to be absorbed through the skin in toxic amounts. Promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

NITRIC ACID CAS: 7697-37-2; Chemical Formula: HNO₃ H.S. No. 1286

OSHA has an 8-hour TWA limit of 2 ppm for nitric acid in construction and maritime. There is no limit in agriculture. The ACGIH has the same TLV*-TWA and a 15-minute TLV*-STEL of 4 ppm, and NIOSH recommends a TWA limit of 2 ppm. OSHA's proposal retains the 8-hour TWA PEL of 2 ppm and adds a STEL of 4 ppm for nitric acid in construction and maritime; the Agency also proposes both limits in agriculture. NIOSH concurs (Ex. 8-47, Table N1) with these limits, which are identical to those recently established for this substance in general industry.

Nitric acid is a fuming colorless or yellowish liquid. Nitric acid is used to destroy residues of organic matter, to dissolve noble metals, for etching and cleaning metals, and in the manufacture of ammonium nitrate for fertilizer (ACGIH 1986, p. 428; Hawley's 1987, p. 824).

Rats receiving a single exposure to nitric acid mist at a concentration of 63 mg/m3 exhibited no apparent adverse effects (Diggle and Gage 1954/Ex. 1-729). Chronic exposure to airborne nitric acid vapor or mist at unspecified levels was reported to cause chronic bronchitis, pneumonitis (Fairhall 1957i. as cited in ACGIH 1986/Ex. 1-3, p. 428), and tooth erosion (Lynch and Bell 1947) Ex. 1-793]. Nitric acid's irritant potential is considered similar to that of other strong acids; it typically exists in conjunction with nitrogen dioxide, which is regarded as being more hazardous (ACGIH 1986/Ex.1-3, p. 428).

OSHA is retaining the 8-hour TWA PEL of 2 ppm and proposing to add a STEL of 4 ppm for nitric acid in construction and maritime; the Agency is also proposing both limits in agriculture. The Agency preliminarily concludes that these limits will protect workers in these sectors against the significant risk of irritation, chronic pulmonary disease, and dental erosion, which constitute material impairments of health. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

p-NITROANILINE CAS: 100-01-6; Chemical Formula: NO₂C₆H₄NH₂ H.S. No. 1287

OSHA has a limit of 1 ppm TWA (6 mg/m³) for p-nitroaniline (PNA), and a skin notation, in construction and maritime. There is no limit in agriculture. The ACGIH has a TLV°-TWA of 3 mg/m³, with a skin notation. There is no NIOSH REL. OSHA is proposing an 8-hour TWA of 3 mg/m³ and a skin notation for p-nitroaniline in construction, maritime, and agriculture. NIOSH concurs (Ex. 8-47, Table N1) that this limit is appropriate for this substance. This is the limit recently established for PNA in general industry.

para-Nitroaniline usually exists in the form of yellow needles. p-Nitroaniline is used in medicinals for poultry, as an intermediate for dyes and antioxidants, and as a gasoline gum inhibitor and corrosion inhibitor (ACGIH 1986, p. 430; Hawley's 1987, p. 826).

Exposure to p-nitroaniline causes convulsions in experimental animals (RTECS 1991). The oral LD₅₀ in rats is 750 mg/kg (RTECS 1991). Dogs administered a single intravenous injection of 15 mg/kg p-nitroaniline developed methemoglobinemia (Clayton and Clayton 1981, p. 2416). Administered to mice on days 6 to 13 of pregnancy at a dose of 1200 mg/kg/day, p-nitroaniline caused maternal death or systemic toxicity (reduced weight gain and a

reduction in the number of litters and in pup survival (Hardin et al. 1987, in Teratog. Carcinog. Mutag. 7:29–48).

p-Nitroaniline is readily absorbed through the skin and is a strong methemoglobin-forming agent; prolonged exposure can cause liver damage (ACGIH 1986/Ex. 1-3, p. 430). Anderson (1946/Ex. 1-1049) reported several cases of PNA-poisoning among shipboard workers assigned to clean up a p-nitroaniline spill; one man with a history of liver disease became laundiced and died, and the other exposed workers became cyanotic and complained of headache, sleepiness, weakness, and respiratory distress (Anderson 1946/Ex. 1-1049). It has also been reported that children who ingested p-nitroaniline that was contained in wax crayons subsequently became ill (Rieders and Brieger 1953/Ex.

Several investigators (Anderson 1946/ Ex. 1-1049; Gupta 1953, Fairhall 1957), both as cited in ACGIH 1986/Ex. 1-3, p. 430; Linch 1974/Ex. 1-747) have concluded that the nitroanilines are more hazardous than aniline, and, on this basis, OSHA established a PEL for PNA in general industry that is lower than the PEL for aniline.

OSHA is proposing a PEL of 3 mg/m3 as an 8-hour TWA for p-nitroaniline, and a skin notation, in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risk of methemoglobinemia and liver damage, both of which constitute material health impairments that are associated with exposure to PNA. A skin notation is necessary because this substance is readily absorbed through the skin in toxic amounts. Promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

NITROMETHANE
CAS: 75–52–5; Chemical Formula:
CH₃NO₂
H.S. No. 2120

OSHA's permissible exposure limit for nitromethane in general industry, construction, and maritime is an 8-hour TWA of 100 ppm. There is no limit in agriculture. The ACGIH has a limit for nitromethane of 100 ppm as an 8-hour TLV*-TWA. The ACGIH TLV* for nitromethane was set on the basis of analogy with nitroethane. NIOSH has no REL. OSHA is proposing to establish an 8-hour TWA of 100 ppm for nitromethane in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Nitromethane is a colorless, oily liquid with a mild fruity odor. This substance is used as a solvent for cellulosic compounds, polymers, waxes, and fats; in chemical synthesis; as a rocket fuel; and as a gasoline additive (ACGIH 1986, p. 439; Merck 1983, p. 949).

Nitromethane causes eye and mucous membrane irritation and central nervous system effects in humans; in animals, it causes irritation, central nervous system depression, and kidney and liver damage. In rats and mice, the oral LDsos are 940 mg/kg and 960 mg/kg. respectively, for an unspecified period of time (RTECS 1990). The lowest lethal inhalation dose in monkeys is 1000 ppm for an unspecified time (RTECS 1990). Severe eye irritation occurs in animals (species unspecified) exposed to a 500ppm concentration of nitromethane (AIHA 1978). Rabbits exposed to a 10,000-ppm concentration of this substance for 6 hours showed signs of weakness, ataxia, muscular incoordination, and convulsions before death; exposure to the same concentration for a period of 3 hours was not fatal to rabbits (Clayton and Clayton 1982, pp. 4153-4155; Machle et al. 1940, in Proctor, Hughes, and Fischman 1988, p. 377). Both liver and kidney damage were seen in acutely poisoned animals at autopsy (Stokinger 1982; Machle et al. 1940, in Proctor, Hughes, and Fischman 1988, p. 377) Eight 6-hour exposures to a 1000-ppm concentration of nitromethane was fatal to an exposed monkey (Stokinger 1982; Machle et al. 1940, in Proctor, Hughes, and Fischman 1988, p. 377). Rats and rabbits exposed to 98 or 745 ppm of nitromethane 5 days/week for 24 weeks showed reductions in weight gain (rats in the high-dose group) and effects on the thyroid (rabbits in both dose groups) (Lewis et al., 1979, J. Environ. Pathol. Toxicol. 2(5):233). At autopsy, rabbits from both treatment groups had signs of pulmonary edema and other pulmonary effects (Lewis et al. 1979).

In humans, nitromethane causes central nervous system depression, and exposure to this substance also causes irritation of the skin and mucous membranes (Gosselin, Smith, and Hodge 1984, p. II–143). The signs and symptoms of overexposure in humans include anorexia, nausea, vomiting, and diarrhea (AIHA 1978).

Based on this evidence in humans and animals, OSHA preliminarily concludes that, in the absence of a limit for nitromethane, workers in agriculture are at significant risk of experiencing its exposure-related effects. OSHA believes that establishing a limit of 100 ppm as an 8-hour TWA will significantly reduce

these risks of material health impairment. Promulgation of this limit will also make OSHA's PEL for nitromethane consistent across all OSHA-regulated sectors.

NITROTOLUENE

CAS: 88-72-2 (o-isomer); 99-08-1 (m-isomer); 99-99-0 (p-isomer); Chemical Formula: CH₃C₆H₄NO₂

H.S. No. 1292

OSHA has an 8-hour TWA limit of 5 ppm, with a skin notation, for nitrotoluene in construction and maritime. There is no PEL in agriculture. The ACGIH has a TLV®-TWA of 2 ppm, also with a skin notation. NIOSH has no REL. OSHA is proposing a PEL of 2 ppm as an 8-hour TWA, and a skin notation, in construction, maritime, and agriculture, and NIOSH concurred with this limit (Ex. 8-47, Table N1) when it was recently established for nitrotoluene in general industry.

The ortho- and meta-isomers of nitrotoluene are yellow liquids; the paraisomer is also yellow, but exists in crystalline form. All isomers of nitrotoluene are used in organic synthesis in the production of toluidine, tolidine, fuchsia, and various synthetic dyes (ACGIH 1986, p. 444; Hawley's

1987, pp. 833-834).

Nitrotoluene is one of the aromatic nitrogen compounds that may cause methemoglobin formation. The oral LD50 in rats is 1072 mg/kg for the m-isomer (RTECS 1991). For the o-isomer, the oral LD₅₀ in rats is 891 mg/kg (RTECS 1991). In rats, the oral LD50 is 1960 mg/kg (RTECS 1991). Administered to rats orally for 30 days at doses that were 10 to 20 percent of the LD50 doses, mnitrotoluene caused methemoglobinemia (Vasilenko et al. 1972). A mixture of the three isomers administered to rats in their diet increased the number of leukocytes in their blood, as well as their methemoglobin level (Kasochevskaya 1967).

Linch (1974/Ex. 1–747) has studied the nitrotoluene isomers and reported that they have relatively low hemotoxic potential; he considered nitrotoluene comparable to aniline in its toxic effects (Linch 1974/Ex. 1–747). Chronic exposure is believed to cause anemia (Clayton and Clayton 1981, p. 2473).

In construction, maritime, and agriculture, OSHA is proposing an 8-hour TWA limit of 2 ppm, and a skin notation, for nitrotoluene. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risk of methemoglobinemia, a material health impairment that is associated with exposure to this substance. The skin notation is necessary because of

nitrotoluene's capacity to penetrate the skin in toxic amounts. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. NONANE CAS: 111-84-2; Chemical Formula:

CH₃(CH₂)₇CH₃ H.S. No. 1293

OSHA has no limit for nonane in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 200 ppm for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N1) that the proposed limit is appropriate. OSHA is proposing an 8-hour TWA PEL for nonane of 200 ppm in construction, maritime, and agriculture. This is the limit recently established for nonane in general industry.

Nonane is a colorless liquid used in biodegradable detergents, as a distillation chaser, and in organic synthesis (ACGIH 1986, p. 445; Hawley's

1987, p. 836).

The toxicity of nonane is approximately equal to that of VM&P naphtha. Naphtha has a 4-hour inhalation LC50 in rats of 3400 ppm, while nonane has an LC50 of 3200 ppm (Carpenter, Kinkead, Geary et al. 1975a/ Ex. 1-302; Carpenter, Geary, Myers et al. 1978/Ex. 1-301). These investigators found a no-effect level of 590 ppm for rats exposed to nonane 6 hours/day, 5 days/week for a 65-day period; under the same exposure conditions, a noeffect level of 560 ppm was reported for rats exposed to VM&P naphtha (Carpenter, Kinkead, Geary et al. 1975a/ Ex. 1-302; Carpenter, Geary, Myers et al. 1978/Ex. 1-301). Earlier studies of octane and heptane have shown much higher LC50 values in mice, i.e., 13,500 ppm and 16,000 ppm, respectively, for 30- to 60-minute exposures (Flury and Zernik 1931j/Ex. 1-994). Swann and associates (1974/Ex.1-124) have reported similarly high LD50 values in mice for octane and hexane; mice died from respiratory arrest after 3 to 5 minutes of exposure to 16,000 ppm of octane or to 48,000 ppm of hexane (Swann, Kwon, and Hogan 1974/Ex. 1-

Based on this evidence, OSHA is proposing an 8-hour TWA limit of 200 ppm for nonane in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risk of narcosis, a material impairment of health that is associated with occupational exposure to nonane. The Agency believes that the proposed PEL will substantially reduce this risk. In addition, promulgation of this limit will

make OSHA's PEL for this substance consistent across all regulated sectors OXALIC ACID CAS: 144-62-7; Chemical Formula: H₂C₂O₄ H.S. No. 1299

In construction and maritime, OSHA currently has a limit of 1 mg/m³ for oxalic acid. There is no limit in agriculture. NIOSH has no REL but concurs (Ex. 8–47, Table N1) with the limits being proposed. The ACGIH has a TLV*–TWA of 1 mg/m³ and a TLV*–STEL of 2 mg/m³. OSHA is retaining the 8-hour TWA limit of 1 mg/m³ for oxalic acid and proposing to add a STEL of 2 mg/m³ in construction and maritime; the Agency is also proposing these limits in agriculture. These are the limits recently established for oxalic acid in general industry.

Anhydrous oxalic acid usually occurs in the form of a white powder; the dihydrate form is a colorless, odorless, crystalline substance. Oxalic acid is used as an automobile radiator cleanser, a purifying agent and chemical intermediate, in leather tanning, in textile bleaching, and in printing and dyeing (Hawley's 1987, p. 862).

Oxalic acid is known to produce severe burns of the eyes, mucous membranes, and skin (Windholz 1983d/Ex. 1–835, p. 991). There have been human fatalities from ingesting as little as 5 grams of oxalic acid. It appears that these deaths were caused by oxalic acid's ability to disturb the calciumpotassium balance in critical tissues (Klauder, Shelanski, and Gabriel 1955/Ex. 1–1057). Solutions of 5- to 10-percent oxalic acid have also been reported to irritate the skin on prolonged exposure.

Because of oxalic acid's severe acute toxicity, OSHA is retaining the 8-hour TWA limit of 1 mg/m3 PEL and proposing to add a STEL of 2 mg/m3 in construction and maritime; the Agency is also proposing both limits in agriculture. OSHA preliminarily concludes that both of these limits are required to protect exposed workers in these sectors from the significant risk of severe eye and skin burns and respiratory tract irritation, which are material health impairments associated with occupational exposures to this substance. OSHA believes that the proposed PELs are necessary to substantially reduce these risks. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

PERCHLORYL FLUORIDE CAS: 7616-94-6; Chemical Formula: CO₃F H.S. No. 1309

In construction and maritime, OSHA's 8-hour TWA limit for perchloryl fluoride is 3 ppm. There is no PEL in agriculture. The ACGIH has a TLV*-TWA of 3 ppm and a TLV*-STEL of 6 ppm for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the proposed limits. OSHA is retaining the 8-hour TWA PEL of 3 ppm and proposing to add a STEL of 6 ppm for perchloryl fluoride in construction and maritime. The Agency is also proposing these limits, which were recently established for perchloryl fluoride in general industry, in agriculture.

Perchloryl fluoride is a colorless noncorrosive gas or liquid with a sweet odor. It is used as an antioxidant in rocket fuels, and as an oxidizing and fluorinating agent in chemical synthesis (Hawley's 1987, p. 887; ACCIH 1986, p.

466.3].

Perchloryl fluoride is an irritant of the eyes, mucous membranes, and upper respiratory tract. The 4-hour LC₆₀s in rats and mice are 385 and 630 ppm, respectively. Dogs exposed for 4 hours to 220- to 450-ppm concentrations of the vapor, followed by exposure to 620 ppm for 2.5 hours, became hyperpneic and cyanotic and showed increased methemoglobin. Dogs succumbing to these exposures had pigment deposition in the liver, spleen, and bone marrow; alveolar hemorrhage and collapse; and emphysema (Greene, Colbourn, Donati, and Weeks 1960, as cited in ACGIH

1986/Ex. 1-3, p. 466).

Exposure to 185 ppm for 6 hours/day, 5 days/week for 7 weeks killed 18 of 20 rats, 20 of 39 mice, and all exposed guinea pigs (Greene, Colbourn, Donati, and Weeks 1960, as cited in ACCIH 1986/Ex. 1-3, p. 466). These animals had difficulty breathing, became cyanotic, and developed alveolar edema and methemoglobinemia; at autopsy, they showed fluorosis, patchy lungs, enlarged spleens, and hemosiderosis of the kidneys, spleen, and liver. When animals were exposed on a similar regimen but to a concentration of 104 pom for six weeks, all guinea pigs but only one of 20 rats died (Greene, Colbourn, Donati, and Weeks 1960, as cited in ACGIH 1986/Ex. 1-3, p. 466). After a 8-month exposure to 24 ppm, bone fluoride levels increased fourfold in guinea pigs, threefold in rats, and about 50 percent in dogs. Animals exposed at 24 ppm showed no signs of irritation (Greene, Colbourn, Donati, and Weeks 1960, as cited in ACGIH 1986/Ex. 1-3, p. 466].

Workers exposed to an unspecified concentration of perchloryl fluoride reported experiencing upper respiratory

tract irritation even after brief exposures (ACGIH 1986, p. 202). Based on effects seen in animals, severe exposure is expected to cause methemoglobinemia (Proctor, Hughes, and Fischman 1988, p. 402).

In construction and maritime, OSHA is retaining the 8-hour TWA of 3 ppm and proposing to add a STEL of 8 ppm for perchloryl fluoride; OSHA is also proposing both PELs in agriculture. These limits are based on the fluoride content of this compound. The Agency preliminarily concludes that both limits are necessary to protect workers in these sectors from the significant risk of fluorosis and hematologic effects, which constitute material impairments of health that are associated with occupational exposures to perchloryl fluoride. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

PHOSDRIN (MEVINPHOS)
CAS: 7786-34-7; Chemical Formula:
C₂H₁₃O₆P

H.S. No. 1320

In construction and maritime, OSHA's PEL for phosdrin is an 8-hour TWA limit of 0.1 mg/m3, with a skin notation. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 0.01 ppm (0.1 mg/m3) and a TLV*-STEL of 0.03 ppm (0.3 mg/m3), also with a skin notation. In construction, maritime, and agriculture, OSHA is proposing an 8hour TWA of 0.01 ppm and a STEL of 0.03 ppm; the skin notation is retained in construction and maritime and proposed in agriculture. NIOSH concurred (Ex. 8-47, Table N1) with these limits when they were recently established in general industry.

Phosdrin is a colorless liquid. The commercial product is a mixture of cisand trans-isomers that have a yellow color. Phosdrin is used as a contact and systemic insecticide and acaricide (ACGIH 1986, p. 412; Hawley's 1987, p. 784). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

The acute oral LD₅₀ of phosdrin is 4 to 8 mg/kg for male mice and 6 to 8 mg/kg for female rats (Shell Chemical Corporation 1956, as cited in ACGIH 1986/Ex. 1-3, p. 412). Phosdrin is a cholinesterase inhibitor and has been reported to cause slight plasma cholinesterase depression but no decrease in brain cholinesterase activity in rats fed 2 to 5 ppm. The compound may be absorbed dermally and by inhalation or ingestion; the action of the compound is direct and immediate

(Cleveland and Treon 1961/Ex. 1–476). The dermal LD₅₀ in rats is 4.5 mg/kg (Gaines 1969/Ex. 1–320). Chronic feeding of rats demonstrated a minimal lethal dose of between 100 and 200 ppm. Cholinesterase activity decreased continually when sublethal doses were administered until a maximum reduction in RBC cholinesterase activity of 25 percent was achieved on the 27th day of the administration of 1.5 to 20 mg doses (Huelse and Federspil 1975/Ex. 1–959).

In industry, the primary hazards associated with exposure to phosdrin are absorption of phosdrin through the skin, lung, and mucous membranes, which causes liver damage (Natoff 1970/Ex. 1-966). Phosdrin intoxication is reported to occur in humans, with accompanying symptoms of headache, visual distortion, weakness, cramps, diarrhea, pain, and respiratory distress. Severe exposure may cause convulsions; in one reported case, some symptoms (anxiety, depression, vertigo, and nystagmus) persisted for as long as four months (Zavon, as cited in ACGIH 1986/Ex. 1-3, p. 412).

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 0.01 ppm, a STEL of 0.03 ppm, and a skin notation for phosdrin in construction, maritime, and agriculture. The Agency preliminarily concludes that these limits are necessary to protect workers in these sectors against the significant risk of cholinesterase inhibition and hepatic injury, which are material health impairments associated with exposure to this substance. OSHA believes that the proposed limits will substantially reduce these significant risks. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

PHOSPHORUS OXYCHLORIDE CAS: 10025-87-3; Chemical Formula: POCL₄

H.S. No. 1323

In construction, maritime, and agriculture, OSHA has no limit for phosphorus oxychloride. The ACGIH has a TLV*-TWA of 0.1 ppm and a TLV*-STEL of 0.5 ppm for this substance. NIOSH has no REL but concurred (Ex. 8-47, Table N1) with the proposed limit when it was recently established in general industry. OSHA is proposing an 8-hour TWA PEL of 0.1 ppm for phosphorus oxychloride in construction, maritime, and agriculture.

Phosphorus oxychloride is a colorless, fuming liquid with a pungent odor. It is used in the manufacture of plasticizers, hydraulic fluids, gasoline additives, and fire retarding agents, and as a chlorinating agent and catalyst (ACGIH

1986, p. 485).

The primary hazards associated with inhalation of phosphorus oxychloride vapor are irritation of the eyes and respiratory tract, as well as narcotic effects, gastric irritation, pulmonary edema, and nephritis (International Technical Information Institute 1978/Ex. 1-837). Weeks and associates (1964, as cited in ACGIH 1986/Ex. 1-3, p. 485) reported 4-hour LC50 values for phosphorus oxychloride of 48 ppm and 52 ppm for rats and guinea pigs, respectively. They also observed that ammonia vapor mediates the irritant effects of exposure to phosphorus oxychloride without significantly altering this LC50 value (Weeks, Downing, Musselman et al. 1964, as cited in ACGIH 1986/Ex. 1-3, p. 485).

Both chronic and acute occupational intoxication have been reported to occur among workers exposed to phosphorus oxychloride (Sassi 1954/Ex. 1–931). Acute exposure to the vapor causes burns, redness and tearing of the eyes, cough, and pain in the chest (HSDB 1991). In contact with the eyes, the vapor may cause slow-healing burns

(Grant 1974, p. 829).

Based on this evidence, OSHA is proposing a PEL of 0.1 ppm (8-hour TWA) for phosphorus oxychloride in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will reduce the significant risk of narcosis and systemic poisoning among workers in these sectors. OSHA considers these adverse health effects and believes that the proposed PEL is necessary to reduce this significant risk. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

PHOSPHORUS PENTASULFIDE CAS: 1314-80-3; Chemical Formula: P₂S₈ H.S. No. 1324

In construction and maritime, OSHA has a limit of 1 mg/m³ as an 8-hour TWA for phosphorus pentasulfide. There is no PEL in agriculture. The ACGIH also has a TLV*-TWA of 1 mg/m³ but adds a 15-minute TLV*-STEL of 3 mg/m³. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the proposed limits. OSHA is proposing an 8-hour TWA PEL of 1 mg/m³ and a 15-minute STEL of 3 mg/m³ for phosphorus pentasulfide in construction, maritime, and agriculture. These are the limits recently established for this substance in general industry.

Phosphorus pentasulfide is a greenishyellow crystalline mass with an odor like that of rotten eggs. Phosphorus pentasulfide is used in the manufacture of insecticides such as parathion and malathion, as an intermediate for lubricant additives, and in flotation agents, safety matches, and ignition compounds (ACGIH 1986, p. 486; Hawley's 1987, p. 912).

In contact with the skin or eyes of rabbits, this substance caused moderate irritation (RTECS 1991). The oral LD₅₀ in rats is 389 mg/kg (RTECS 1991).

The primary hazard associated with exposure to phosphorus pentasulfide is respiratory irritation (Smyth 1956/Ex. 1–759). In the presence of moisture, phosphorus pentasulfide is rapidly hydrolyzed to phosphoric acid and hydrogen sulfide. The ACGIH (1986/Ex. 1–3, p. 485) considers phosphorus pentasulfide to be as toxic as phosphoric acid.

Based on this evidence, OSHA is retaining the 8-hour TWA PEL of 1 mg/m³ and proposing to add a 15-minute STEL of 3 mg/m³ for phosphorus pentasulfide in construction and maritime. OSHA is also proposing both limits in agriculture. The Agency preliminarily concludes that these limits are necessary to reduce the significant risk of respiratory irritation, a material health impairment. These are the limits

recently established for phosphorus pentasulfide in general industry. PHTHALIC ANHYDRIDE

CAS: 85-44-9; Chemical Formula:

C₆H₄(CO)₂O H.S. No. 1326

In construction and maritime, OSHA has an 8-hour TWA limit of 2 ppm for phthalic anhydride. There is no limit in agriculture. The ACGIH has a limit of 1 ppm TWA for phthalic anhydride.

NIOSH has no REL but concurs (Ex. 8-47, Table N1) that the proposed limit is appropriate. OSHA is proposing an 8-hour TWA PEL of 1 ppm for phthalic anhydride in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry.

Phthalic anhydride takes the form of white crystalline needles and has a mild odor. It is used in the manufacture of insecticides, pharmaceuticals, resins, polyesters, dyes, and plasticizers (ACGIH 1986, p. 487; Hawley's 1987, p.

915).

The primary exposure hazards associated with phthalic anhydride are severe skin, eye, and respiratory irritation. The substance can also produce skin and, perhaps, pulmonary sensitization. The oral LD₅₀ in rats is 4020 mg/kg (RTECS 1991). In contact with the skin of rabbits, phthalic anhydride caused mild irritation; instillation in the eye led to severe irritation (RTECS 1991). Exposure to the

heated vapor of phthalic anhydride at unidentified concentrations caused pulmonary injury; in contact with the skin of guinea pigs, this substance caused sensitization (NRC 1977, p. 756). Baader (1955/Ex. 1–1139) has reported irritant effects in experimental animals exposed to 30 mg/m³ (approximately 5 ppm) phthalic anhydride in air.

Workers exposed to phthalic anhydride concentrations of about 4 ppm reported experiencing mucous membrane irritation, and at 5 ppm, conjunctivitis developed in these

workers (AIHA 1967).

In studies of workers exposed to unspecified concentrations of phthalic acid vapors and phthalic anhydride, symptoms of respiratory tract injury as well as bronchitis, eye irritation, cough, bloody sputum, and nasal bleeding have been reported (Proctor, Hughes and Fischman 1988, p. 415). Several of these workers also developed bronchial asthma and skin sensitization (Proctor, Hughes, and Fischman 1988, p. 415). Respiratory sensitization has been confirmed by patch testing in at least one case (Maccia, Bernstein, Emmett, Brooks 1976).

Based on this evidence; OSHA is proposing an 8-hour TWA limit of 1 ppm for phthalic anhydride in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will reduce the significant risk among workers in these sectors of respiratory irritation and skin and pulmonary sensitization, which constitute material impairments of health. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

PINDONE

CAS: 83–26–1; Chemical Formula: C₁₄H₁₄O₃
H.S. No. 2132

In general industry, construction, and maritime, OSHA's permissible exposure limit for pindone is 0.1 mg/m³ as an 8-hour TWA. There is no limit for this substance in agriculture. The ACGIH has a TLV*-TWA of 0.1 mg/m³ for pindone; NIOSH has no REL but concurs (Ex. 8–47, Table N1) with the limit being proposed. OSHA is proposing to establish a PEL of 0.1 mg/m³ as an 8-hour TWA for pindone in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Pindone (also called Pival) is an odorless substance that takes the form of bright yellow crystals. Pindone is used primarily as a rodenticide and insecticide. It is also used as a pharmaceutical intermediate (ACGIH

1986, p. 491; Hawley's 1987, p. 923). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Pindone causes disturbances in blood coagulation in humans and animals; the mechanism of pindone's action is vitamin K antagonism, which, in turn, inhibits prothrombin formation (Proctor, Hughes, and Fischman 1988, p. 417). The oral LD50s in rats, dogs, and rabbits are 280 mg/kg, 75 mg/kg, and 150 mg/kg, respectively (RTECS 1988). Ingestion of a single large dose of pindone caused death in rats as a result of pulmonary and visceral congestion (U.S. Public Health Service 1956, in Proctor, Hughes, and Fischman 1988, p. 417). Although the single-dose LD50 in dogs is 75 mg/kg, daily doses of as little as 2.5 mg/kg are fatal in dogs after a few days (Worthing 1983, in HSDB 1988). Rabbits given oral doses of 1 mg/kg/day survived for an average of 8 to 10 days; acutely poisoned animals had evidence of hemorrhage throughout the muscles and organs at autopsy (HSDB 1988). The offspring of pregnant dogs given pindone were stillborn or died shortly after birth; autopsy of the pups revealed severe hemorrhage in most organs (Fitzek and Gembardt 1977, in HSDB 1988). Chronic exposure to low doses of pindone causes death in experimental animals; the cause of death in these cases is multiple internal hemorrhage (Proctor, Hughes, and Fischman 1988, p. 417).

In humans, pindone reduces blood coagulation and occasionally produces symptoms similar to those caused by warfarin, such as anorexia, nausea, vomiting, and diarrhea (Goodman 1975, in HSDB 1988; Merck 1983, p. 1073). Swallowing repeated small doses of pindone may cause generalized bleeding, such as nose bleeds or excessive bleeding from minor cuts. Individuals may experience stomach and back pain for several days after pindone exposure (NIOSH/OSHA Occupational Health Guideline 1981, p. 1).

Based on this evidence in humans and animals, OSHA preliminarily concludes that pindone is an anticoagulant causing internal hemorrhaging. In the absence of a limit for pindone, OSHA believes that workers in agriculture are at significant risk of experiencing this adverse health effect; the Agency believes that establishing a PEL of 0.1 mg/m³ for pindone will substantially reduce the risk of this material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this

substance consistent across all regulated sectors. PROPARGYL ALCOHOL CAS: 107-19-7; Chemical Formula: HC=CCH₂OH H.S. No. 1335

In construction, maritime, and agriculture, OSHA has no limit for propargyl alcohol. The ACGIH has a TLV*-TWA of 1 ppm, with a skin notation, for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the proposed limit. OSHA is proposing an 8-hour TWA PEL of 1 ppm for propargyl alcohol in construction, maritime, and agriculture. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

Propargyl alcohol is a colorless liquid with a mild, geranium-like odor (HSDB 1991). This substance is used as a solvent stabilizer, corrosion inhibitor, chemical intermediate, and soil fumigant (ACGIH 1986, p. 496).

In rats, guinea pigs, and mice, the oral LD₅₀s are 70, 60, and 50 mg/kg, respectively; the 2-hour inhalation LC₅₀ in both the rat and mouse is about 850 ppm (NIOSH 1977i/ Ex. 1–1182). The dermal LD₅₀ in rabbits is 88 mg/kg (RTECS 1990).

Propargyl alcohol is a primary skin irritant, but it is not a skin sensitizer (Antara Chemicals 1952, as cited in ACGIH 1986/Ex. 1-3, p. 496). The toxicity of propargyl alcohol is estimated to be equal to that of allyl alcohol (oral LD50 in rats of 64 mg/kg) (NIOSH 1977i/Ex. 1182). The ACGIH limit is based on the structural and toxicological similarity of propargyl alcohol to allyl alcohol (ACGIH 1986/ Ex. 1-3, p. 496). Propargyl alcohol also causes degenerative changes in liver and kidneys in an 89-day rat study (Rowe and McCollister (1982) in Patty's Industrial Hygiene and Toxicology 1982, Vol. 2C, p. 4673).

Based on this evidence, OSHA is proposing an 8-hour TWA for propargyl alcohol of 1 ppm, with a skin notation, in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that these limits are necessary to protect workers in these sectors against the significant risk of skin and mucous membrane irritation, CNS depression, and liver and kidney damage associated with exposure to this substance. OSHA believes that these health effects constitute material impairments of health. In addition, promulgation of the proposed PEL will make OSHA's limit for propargyl alcohol consistent across all regulated sectors.

PROPIONIC ACID

CAS: 79-09-4; Chemical Formula: CH₃CH₂COOH H.S. No. 1336

OSHA has no limit for propionic acid in construction, maritime, and agriculture. The ACGIH has a TLV*-TWA of 10 ppm for this substance; the TLV* was set on the basis of analogy with acetic acid (10 ppm 8-hour TLV*). NIOSH has no REL but concurred (Ex. 8-47, Table N1) that this limit when it was recently established is appropriate in general industry. OSHA is proposing an 8-hour TWA PEL of 10 ppm for propionic acid in construction, maritime, and agriculture.

Propionic acid is a colorless, oily liquid with a pungent odor. Propionic acid and propionates are used as herbicides, fungicides, mold inhibitors, grain and wood chip preservatives, emulsifying agents, in pharmaceuticals, and in artificial fruit flavors (ACGIH 1986, p. 498; Hawley's 1987, p. 971).

The primary health effects associated with exposure to propionic acid are skin burns and irritation of the eyes and respiratory system. Smyth, Carpenter, Weil, and co-workers (1962/Ex. 1-441) reported that the oral LD₅₀ in rats is 4.3g/kg; NIOSH (1977i/Ex. 1-1182) stated that the intravenous LD₅₀ in mice is 625 mg/kg and the skin absorption LD₅₀ in rabbits is 500 mg/kg. Inhalation of the saturated vapor for eight hours caused no fatalities in rats (ACGIH 1986/Ex. 1-3, p. 498).

Acute industrial exposures to propionic acid have been reported to cause mild to moderate skin burns, eye irritation, and, in a single incident, asthmatic cough. No irritation was observed when human volunteers were exposed to concentrations of propionic acid averaging below 0.25 ppm, with excursions to 2.1 ppm, over an eighthour period (Dow Chemical Company 1977o, as cited in ACGIH 1986/Ex. 1–3, p. 498).

Based on this evidence, OSHA is proposing an 8-hour TWA limit of 10 ppm for propionic acid in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit is necessary to protect workers in these sectors against the significant risk of eye and respiratory tract irritation, which are material impairments of health. This is the limit recently established for this substance in general industry.

n-PROPYL ACETATE
CAS: 109-60-4; Chemical Formula:
CH₃COOCH₂CH₂CH₃
H.S. No. 1338

In construction and maritime, OSHA has an 8-hour TWA limit of 200 ppm for n-propyl acetate. There is no PEL in

agriculture. The ACGIH also has a 200-ppm TLV*-TWA but adds a TLV*-STEL of 250ppm. NIOSH has no REL but concurs (Ex. 8-47, Table N1) that these limits are appropriate; these are the limits established recently in general industry. OSHA is proposing limits for n-propyl acetate of 200 ppm as an 8-hour TWA and 250 ppm as a 15-minute STEL; these limits would apply in construction, marltime, and agriculture.

n-Propyl acetate is a pleasantsmelling liquid. This substance is used in flavoring agents, perfumes, natural and synthetic resins, lacquers, plastics and organic synthesis, and as a solvent for nitrocellulose and other cellulose derivatives (ACGIH 1986, p. 500;

Hawley's 1987, p. 972).

The primary health effects associated with exposure to n-Propyl acetate are narcosis and eye and respiratory irritation. The oral LD₅₀ in rats is 9370 mg/kg, and the lowest lethal concentration in the same species is 8000 ppm for 4 hours (RTECS 1991). In contact with the skin of rabbits, this substance caused mild irritation (RTECS 1991). n-Propyl acetate's narcotic action is 1.3 times that of ethyl acetate; salivation and irritation of cats' eyes occurred at a concentration of 2600 ppm (Flury and Wirth 1933, as cited in ACCIH 1986/Ex. 1–3, p. 500).

n-Propyl acetate appears to be more toxic than isopropyl acetate or ethyl acetate but less so than n-butyl acetate (ACGIH 1986, p. 500). Exposure to a concentration of 200 ppm causes eye irritation in humans, and exposure to higher concentrations causes nasal and upper respiratory tract irritation (Parmezziani 1983, p. 782). Repeated or prolonged contact of the skin may cause defatting and dermatitis (Parmezziani

1983, p. 782).

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 200 ppm and a 15-minute STEL of 250 ppm for n-propyl acetate in construction, maritime, and agriculture. The Agency preliminarily concludes that these limits are necessary to prevent a significant risk of narcosis and eye and respiratory tract irritation among workers in these sectors. OSHA considers these effects material impairments of health. These are the limits recently established for this substance in general industry. PROPYL ALCOHOL

CAS: 71-23-8; Chemical Formula: CH₂CH₂CH₂OH H.S. No. 1339

In construction and maritime, OSHA has a limit of 200 ppm (8-hour TWA) for n-propyl alcohol. There is no limit in agriculture. The ACGIH has the same TWA limit but adds a 250-ppm 15-

minute STEL and a skin notation.
NIOSH has no REL but concurs (Ex. 8–47, Table N1) that these limits are appropriate; these are the limits recently established in general industry. OSHA is proposing limits for propyl alcohol in construction, maritime, and agriculture of 200 ppm as an 8-hour TWA and 250 ppm as a 15-minute STEL.

Propyl alcohol is a colorless liquid with an alcohol-like odor. Propyl alcohol is used in brake fluids and polishing compounds, as a solvent for waxes, vegetable oils and resins, as a degreasing agent and antiseptic, and as a chemical intermediate (ACGIH 1986, p.

500; Hawley's 1987, p. 972).

The primary health effects associated with exposure to propyl alcohol are irritation and narcosis. The oral LD50 for propyl alcohol in rats is 1.9 g/kg (Smyth, Carpenter, Weil, and Pozzani 1954/Ex. 1-440). The dermal LD50 in rabbits is 5040 mg/kg, and the LC50 in mice is 48 g/ m3 (RTECS 1991). Starrek reported deep narcosis in mice inhaling the vapor at a concentration of 4100 ppm for 240 minutes and of 24,500 ppm for 60 minutes; ataxia appeared in 90 to 120 minutes on exposure to 3250 ppm (Starrek 1938/Ex. 1-872). These effects are almost twice as intense as those reported for exposure to the vapor of isopropyl alcohol. Rats intubated or given subcutaneous injections of propyl alcohol in carcinogenicity bioassays developed tumors (both benign and malignant) at multiple sites; animals also showed severe liver injury and hematopoietic effects (Gibel, Lohs, and Wildner 1975).

Nelson, Enge, Ross, and associates (1943/Ex. 1–66) reported mild eye, nose, and throat irritation in humans exposed at 400 ppm to the vapor of isopropyl alcohol, but no data exist on human sensory response to propyl alcohol vapor. The ACGIH (1986/Ex. 1–3, p. 500) reports that many industrial hygienists consider the vapor of propyl alcohol to be more irritating to the throat than the

vapor of the isomer.

Based on this evidence, OSHA is retaining the 8-hour TWA PEL of 200 ppm in construction and maritime, proposing to add a STEL of 250 ppm, and proposing to extend both limits to agriculture. The Agency preliminarily concludes that these limits are necessary to protect workers in these sectors against the significant risk of narcosis and irritation, both material impairments of health, that are associated with exposure to this substance. These are the limits recently established for this substance in general industry.

PROPYLENEIMINE

CAS: 75-55-8; Chemical Formula: C₃H₇N H.S. No. 2135

In general industry, construction, and maritime, OSHA's permissible exposure limit for propyleneimine is 2 ppm as an 8-hour TWA; this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. There is no limit for propyleneimine in agriculture. The ACGIH has a TLV*-TWA of 2 ppm, with a skin notation, for propyleneimine. The ACCIH TLV* for propyleneimine was set by analogy with ethyleneimine, a potential human carcinogen (ACGIH 1986, p. 504). NIOSH has no REL for this substance but concurs with the limit being proposed (Ex. 8-47). OSHA is proposing an 8-hour TWA limit of 2 ppm, with a skin notation, for propyleneimine in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated

Propyleneimine, also called 2-methyl aziridine, is a clear, fuming liquid with a strong ammonia-like odor. This substance is used as a chemical intermediate in the production of paper, textile, and rubber and pharmaceutical chemicals and as an ingredient in latex surface coatings (ACGIH 1986, p. 504;

Hawley's 1987, p. 974).

Propyleneimine causes severe eye, mucous membrane, and skin irritation in humans and animals and is carcinogenic in animals. The oral LDso in rats is 19 mg/kg (RTECS 1991). The lowest lethal concentrations in rats and guinea pigs are 500 ppm over 4 hours and 500 ppm for 1 hour, respectively (RTECS 1991). The dermal LD₅₀ in guinea pigs is 43 mg/ kg (RTECS 1991). Rabbits exhibited signs of severe eye irritation when 0.025 mg of propyleneimine was instilled into their eyes (RTECS 1989); injury was graded 9 on an ascending severity scale of 1 to 10 (Grant 1986, p. 770). Rats given 20 mg/kg propyleneimine in water by gavage twice weekly for 28 weeks developed gliomas, ear-duct squamous cell carcinomas, intestinal adenocarcinomas, leukemias, and breast tumors (Ulland et al. 1971, in IARC 1975, Vol. 9, p. 63). In another study, rats given 10 mg/kg propyleneimine by gavage for 60 weeks developed leukemias, gliomas, ear-duct squamous-cell carcinomas, intestinal adenocarcinomas, and breast tumors (Ulland et al. 1971, in IARC 1975, Vol. 9, p. 63). Based on these findings, the International Agency for Research on Cancer has concluded that the evidence for the carcinogenicity of propyleneimine in animals is sufficient (IARC 1975, Vol. 9, p. 64). Propyleneimine is mutagenic in bacterial

test systems without metabolic activation (RTECS 1991; HSDB 1985).

The toxicity of propyleneimine is believed to be from ¼ to ½ that of ethyleneimine (Carpenter et al. 1948, in ACGIH 1986, p. 504). According to the ACGIH, propyleneimine should be classified as a carcinogen of "intermediate * * * potency" (ACGIH 1986, p. 504). There are no reports of systemic effects in workers exposed to this substance.

Based on this evidence and by analogy with ethyleneimine, OSHA preliminarily concludes that propyleneimine is an irritant and potential occupational carcinogen. OSHA believes that, in the absence of a limit for this substance, workers in agriculture are at significant risk of experiencing these exposure-related effects. The Agency believes that establishing a PEL of 2 ppm as an 8-hour TWA for propyleneimine will substantially reduce these risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. PROPYLENE OXIDE

CAS: 75-56-9; Chemical Formula: CH₃CHOCH₂ H.S. No. 1344

In construction and maritime, OSHA has an 8-hour TWA limit of 100 ppm for propylene oxide. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 20 ppm for this substance. OSHA is proposing an 8-hour TWA of 20 ppm for propylene oxide in construction, maritime, and agriculture; this is the limit recently established in general industry.

Propylene oxide is a colorless, highly flammable, volatile, and ethereal liquid. Propylene oxide is used as a fumigant and as an intermediate in the production of polyols for detergents, surfactants, propylene glycols, and synthetic lubricants (ACGIH 1986, p. 504;

Hawley's 1987, p. 974).

The health hazards associated with exposure to this substance are primary skin, eye, and respiratory irritation, as well as central nervous system depression. The oral LD50 values in rats and guinea pigs are 930 mg/kg and 690 mg/kg, respectively. In mice, the LC50 is 1740 ppm for 4 hours. Dogs and guinea pigs exposed for 4 hours at 2000 and 4000 ppm, respectively, died (NIOSH 1977i/Ex. 1-1182). Although only some species tolerate daily exposures to 200 ppm, all species tested tolerated 100 ppm without ill effects (Rowe, Hollingsworth, Oyen et al. 1956/Ex. 1-609). Jacobson and associates (1956/Ex. 1-702) considered the toxic effects of

propylene oxide to be one-half to onethird as intense as those of ethylene oxide (Jacobson, Hackley, and Feinsilver 1956/Ex. 1–702).

Corneal burns and skin necrosis, as well as respiratory and pulmonary irritation, have been reported in humans as a result of direct contact with the liquid or vapor of propylene oxide (Patty 1963h/Ex. 1–857); Central nervous system effects, including ataxia, incoordination, and general depression, also occur as a result of exposure to unspecified concentrations.

In the prior rulemaking, OSHA received several comments on propylene oxide. These commenters (Exs. 3-746, 8-47, Table N6B) noted that propylene oxide is a potential occupational carcinogen, based on an NTP bioassay in rats and mice that demonstrates "some evidence" of carcinogenicity in rats and "clear evidence" of carcinogenicity in mice (Ex. 8-47). In response to these commenters, OSHA stated that the Agency is aware of propylene oxide's serious health effects; however, because the primary purpose of the present rulemaking is to ensure consistency in PELs across OSHA-regulated sectors, OSHA is not at this time considering a further reduction in the PEL. The first PEL update, however, will review the literature on propylene oxide.

In construction, maritime, and agriculture, OSHA is proposing an 8-hour TWA limit of 20 ppm for propylene oxide to protect workers in these sectors against the significant risk of primary irritation and CNS depression, which constitute material health impairments that are associated with exposure to propylene oxide. The Agency believes that this limit is necessary to substantially reduce this significant risk. This is the limit recently established for this substance in general industry.

SELENIUM HEXAFLUORIDE CAS: 7783–79–1; Chemical Formula: SeF₆

H.S. No. 2141 OSHA's permissible exposure limit for selenium hexafluoride in general industry, construction, and maritime is 0.05 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV®-TWA of 0.05 ppm for selenium hexafluoride; this limit was established on the basis of selenium hexafluoride's similarity in physiological effect to ozone (ACGIH 1986, p. 518). NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing to establish an 8-hour TWA limit of 0.05 ppm for selenium hexafluoride in agriculture. Promulgation of this limit will make the

PEL for this substance consistent across all OSHA-regulated sectors.

Selenium hexafluoride is a colorless gas. It is used as a gaseous electric insulator (ACGIH 1986, p. 518; Merck 1983, p. 1213).

Selenium hexafluoride causes severe pulmonary irritation in animals; its acute toxicity is about one-half that of ozone (ACGIH 1986, p. 518). Acute toxicity studies in rats, mice, rabbits, and guinea pigs showed that exposure to selenium hexafluoride concentrations of 10 ppm for 4 hours is fatal (Kimmerle 1960, in ACGIH 1986, p. 518). Exposure of animals of these species to a concentration of 5 ppm selenium hexafluoride caused pulmonary edema; exposure to a 1-ppm concentration produced no grossly observable effects (Kimmerle 1960, in ACGIH 1986, p. 518). Exposing rats, mice, rabbits, and guinea pigs to a 5-ppm concentration of selenium hexafluoride for 1 hour/day for 5 days caused signs of pulmonary injury; exposure to a 1-ppm concentration on the same regimen caused no effects (Kimmerle 1960, in ACGIH 1986, p. 518).

Based on effects seen in animals, selenium hexafluoride is expected to cause severe respiratory irritation in exposed humans; exposure is also likely to cause selenium poisoning (HSDB 1985; Proctor, Hughes, and Fischman 1988, p. 439). The signs and symptoms of acute selenium poisoning include nausea, vomiting, indigestion, headache, irritability, unstable blood pressure, and yellowish skin (Freiberg 1979, in HSDB 1985). Inhalation exposure can impart a garlic-like odor to the breath (Freiberg 1979, in HSDB 1985).

Based on this evidence, OSHA preliminarily concludes that exposure to selenium hexafluoride may cause severe respiratory irritation and selenium poisoning. OSHA believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these material health impairments and that establishing an 8-hour TWA limit of 0.05 ppm is necessary to reduce this significant risk. Promulgation of this limit also will make the PEL for selenium hexafluoride consistent across all OSHA-regulated sectors.

SILICON TETRAHYDRIDE CAS: 7803-62-5; Chemical Formula: SiH₄ H.S. No. 1361

In construction, maritime, and agriculture, OSHA has no limit for silicon tetrahydride. The ACGIH TLV*-TWA is 5 ppm. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. In construction, maritime, and agriculture, OSHA is

proposing an 8-hour TWA PEL for silicon tetrahydride of 5 ppm. This is the limit recently established for this substance in general industry.

Silicon tetrahydride, a colorless gas, is used in the manufacture of semiconductors. Silicone in a commonly used synonym for silicon tetrahydride.

Silicon tetrahydride is a mild irritant of the eyes and mucous membranes. The LC50 in rats is 9600 ppm for 4 hours (RTECS 1991). Studies of rats exposed to silicon tetrahydride at levels of 126 ppm for one hour (Matheson Gas Products 1971, as cited in ACGIH 1986/Ex. 1-3, p. 528) and at 1400 ppm for six hours (Union Carbide Corporation 1980, as cited in ACGIH 1986/Ex. 1-3, p. 528) have failed to identify any systemic effects associated with exposure to this

Based on this evidence, OSHA is proposing an 8-hour TWA limit of 5 ppm for silicon tetrahydride in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that this limit will protect workers in these sectors from the significant risk of exposure-related eye, skin, and upper respiratory tract irritation, which are material health impairments. This is the limit recently established for this substance in general industry.

STIBINE

CAS: 7803-52-3; Chemical Formula: SbH H.S. No. 2144

In general industry, construction, and maritime, OSHA's current permissible exposure limit for stibine is 0.1 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV®-TWA limit of 0.1 ppm for this substance: this limit was established on the basis of stibine's similarity in physiological effect to arsine, a gas generally found with stibine. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing a PEL of 0.1 ppm for stibine in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Stibine is a colorless gas with a disagreeable, hydrogen sulfide-like odor; it is usually produced inadvertently when acid solutions of antimony are treated with zinc or other reducing agents (ACGIH 1986, p. 586.3). It was formerly used as a fumigating agent and in chemical synthesis (ACGIH 1986, p. 536.3; NIOSH/OSHA Occupational Health Guideline 1981, p. 2).

Stibine is an irritant and a hemolytic igent in both humans and animals. This substance also causes liver and kidney

injury in animals. The lowest lethal concentration (LC10) in mice is 10 ppm for an unspecified period; in guinea pigs, the LC₁₀ is 92 ppm for 1 hour (RTECS 1991). Cats and dogs exposed to a stibine concentration of 40 to 45 ppm for 1 hour developed pulmonary congestion and edema; death occurred within 24 hours of exposure (Webster 1946, in ACGIH 1986, p. 536.3). Guinea pigs developed hemoglobinuria followed by anemia after being exposed to a 65-ppm concentration of stibine for 1 hour (Webster 1946, in Proctor, Hughes, and Fischman 1988, p. 445).

One of the early signs of overexposure to stibine in humans is hemoglobinuria (Dernehl, Stead, and Nau 1943, in Clayton and Clayton 1981, p. 1511). Other signs and symptoms of acute overexposure to stibine include eye irritation, headache, nausea, weakness, slow breathing, and a weak, irregular pulse (Dernehl, Stead, and Nau 1943, in Clayton and Clayton 1981, p. 1511). No clear-cut case of fatal stibine poisoning in humans has been reported because stibine usually occurs in combination with arsine, another hemolytic agent (Clayton and Clayton 1981, p. 1511). Workers concurrently exposed to several gases (arsine, stibine, and hydrogen sulfide) at unmeasured concentrations developed headache, weakness, nausea, abdominal and lumbar pain, hemoglobinuria, hematuria, and anemia (Dernehl, Stead, and Nau 1944, in Proctor, Hughes, and Fischman 1988, p. 445).

Based on this evidence, OSHA preliminarily concludes that exposure to stibine is associated with hemolysis, respiratory irritation, and possible liver and kidney injury. OSHA believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse effects and that establishing a limit of 0.1 ppm as an 8-hour TWA is necessary to reduce these risks of material health impairment. Promulgation of this limit will also make the PEL for stibine consistent across all OSHA-regulated

sectors.

SULFURYL FLUORIDE CAS: 2699-79-8; Chemical Formula: SO₂F₂

H.S. No. 1379

In construction and maritime, OSHA's limit for sulfuryl fluoride is 5 ppm as an 8-hour TWA. There is no PEL in agriculture. The ACGIH has a TLV*-TWA of 5 ppm and a TLV®-STEL of 10 ppm. NIOSH has no REL but concurs (Ex. 8-47, Table N1) that the proposed limits are appropriate. OSHA is proposing an 8-hour TWA PEL of 5 ppm and a 15-minute STEL of 10 ppm for

sulfuryl fluoride in construction. maritime, agriculture. These are the limits recently established for this substance in general industry.

Sulfuryl fluoride is a colorless gas with a sulfide odor. Sulfuryl fluoride is primarily used as an insecticide and fumigant. It is also used in the organic synthesis of drugs and dyes (ACCIH 1986, p. 546; Sittig 1985, p. 820). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

In extensive animal studies conducted by the Dow Chemical Company (1962 and 1970, as cited in ACGIH 1986/Ex. 1-3, p. 548), sulfuryl fluoride was determined to exhibit one-half to onethird the acute inhalation toxicity of methyl bromide. Acute exposures of animals resulted in tremors that later developed into severe convulsions. Pulmonary edema was seen in laboratory animals after a single severe exposure. Repeated exposures of rats, guinea pigs, and mice to 20 ppm sulfuryl fluoride for seven hours per day produced both kidney and lung injury after six months. Some evidence of fluorosis was observed in the incisors of mice, but not in the teeth of the rats or guinea pigs (Dow Chemical Company 1962 and 1970, as cited in ACGIH 1986/ Ex. 1-3, p. 546).

A report by Taxay (1966/Ex. 1-577) that examined an incident of acute workplace overexposure to sulfuryl fluoride noted that abdominal pain, nausea, vomiting, and itching were the major symptoms. On the day after exposure, the serum of the affected worker tested positive for fluoride.

Based on this evidence, OSHA is retaining the 8-hour TWA limit of 5 ppm and proposing to add a STEL of 10 ppm for sulfuryl fluoride in construction and maritime; the Agency is also proposing both limits in agriculture. The Agency preliminarily concludes that these limits will protect workers in these sectors against the significant risks of kidney and lung injury and of fluorosis, which constitute exposure-related material health impairments. These are the limits recently established for this substance in general industry.

TEDP (SULFOTEP) CAS: 3689-24-5; Chemical Formula: (C2H5)4P2S2O5 H.S. No. 2149

OSHA's current permissible exposur limit (PEL) for TEDP (tetraethyldithiopyrophosphate) in construction, maritime, and general industry is 0.2 mg/m3 as an 8-hour

TWA: this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 0.2 mg/m3, with a skin notation, for TEDP. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour TWA limit of 0.2 mg/m3, with a skin notation, for TEDP in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

TEDP, also called Sulfotep, is a vellow, noncombustible liquid with a garlic-like odor. TEDP is an organophosphate pesticide that is used as an insecticide and miticide (ACGIH 1986, p. 541; Merck 1983, p. 1287). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA)

TEDP causes cholinesterase inhibition in humans and animals; the inactivation of cholinesterase causes acetylcholine to accumulate at synapses in the nervous system, skeletal and smooth muscles, and secretory glands (Proctor, Hughes, and Fischman 1988, p. 465). Oral LDsos in rats, mice, and rabbits are 5 mg/kg, 22 mg/kg, and 25 mg/kg, respectively (RTECS 1991). Rats have an LCoo of 38 mg/m3 for 4 hours; in mice, the LCso is 40 mg/m3 for 4 hours (RTECS 1991). In rats and rabbits, the dermal LD₅₀s are 65 mg/kg and 20 mg/kg, respectively (RTECS 1991). TEDP affects the autonomic nervous system in rats, mice, dogs, cats, and rabbits by all routes of exposure (RTECS 1991). The signs and symptoms of TEDP poisoning include hypersalivation, lacrimation, sweating, nasal discharge, vomiting, dyspnea, muscle fasciculation, weakness, and paralysis. Effects on the central nervous system consist of nervousness, ataxia, convulsions, coma, and death due to respiratory failure or cardiac arrest (Clarke 1981, p. 153, in HSDB 1988). Fed at a dietary concentration of 60 ppm for 12 weeks. TEDP produced no symptoms in rats; however, feeding at a dose of 180 ppm caused illness and tissue change (Lehman 1952, in ACGIH 1986, p. 541). TEDP is estimated to be about 1/2 as toxic as parathion (Lehman 1951, in ACGIH 1986, p. 541).

In humans, severe TEDP poisoning can occur by any route of exposure. After inhalation of toxic amounts, respiratory and ocular effects (including a feeling of tightness in the chest, wheezing, laryngeal spasms, cyanosis,

blurred vision, miosis, and tearing) occur within a few minutes of exposure (Proctor, Hughes, and Fischman 1988, p. 465). Gastrointestinal signs and symptoms, such as anorexia, nausea, vomiting, cramps, and diarrhea, appear 15 minutes to 2 hours following the ingestion of TEDP (Proctor, Hughes, and Fischman 1988, p. 465). The accumulation of acetylcholine in the central nervous system, which is caused by TEDP-induced cholinesterase inhibition, can cause tension, anxiety, restlessness, insomnia, neurosis, headache, apathy, and confusion (Klaassen 1986, p. 528). An excess of acetylcholine at the neuromuscular junctions of skeletal muscle causes weakness, involuntary twitching, fasciculations, and paralysis. Recovery usually occurs within one week after the cessation of exposure (Proctor, Hughes, and Fischman 1988, p. 465). Chronic exposure to TEDP concentrations that are too small to cause symptoms immediately can eventually cause poisoning, indicating that TEDP accumulates in the system (Proctor, Hughes, and Fischman 1988, p. 465).

Based on this evidence in humans and animals and by analogy with parathion, OSHA preliminarily concludes that TEDP causes the signs and symptoms associated with cholinesterase inhibition. OSHA believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these effects. OSHA believes that establishing a PEL of 0.2 mg/m3 as an 8-hour TWA, with a skin notation, is necessary to reduce this risk of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. TELLURIUM HEXAFLUORIDE CAS: 7783-80-4; Chemical Formula: TeFe H.S. No. 2151

In general industry, construction, and maritime, OSHA's current permissible exposure limit for tellurium hexafluoride is 0.02 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 0.02 ppm for this substance; the ACGIH limit was established by analogy with the effects of exposure to ozone. NIOSH has no REL but concurs (Ex. 8-47) with the limit being proposed. OSHA is proposing an 8-hour TWA limit of 0.02 ppm for tellurium hexafluoride in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Tellurium hexafluoride is a colorless, noncombustible gas with an unpleasant odor. This substance is used as an analytical reagent in research

laboratories (ACGIH 1986, p. 556; Genium MSDS 1988, No. 250).

Tellurium hexafluoride causes pulmonary irritation in animals; signs and symptoms of exposure in humans include headache and dyspnea. The lowest lethal concentrations in various animal species are 5 ppm for 4 hours in rats, rabbits, and guinea pigs, and 5 ppm for 1 hour in mice (RTECS 1991). Exposed to a concentration of 1 ppm for 4 hours, animals of four species (rats, mice, rabbits, and guinea pigs) showed evidence of pulmonary edema; exposures to concentrations of between 5 and 100 ppm tellurium hexafluoride were fatal to all animals of all experimental species (Kimmerle 1960, in ACGIH 1986, p. 556). A one-hour exposure to a 1-ppm concentration of tellurium hexafluoride for 5 days caused no effects in animals of these four species; the author of this study attributed this finding to the development of tolerance to tellurium hexafluoride's acute effects (Kimmerle 1960, in ACGIH 1986, p. 556).

In humans, exposure to tellurium hexafluoride causes headache and difficult breathing (Cooper 1971; Cerwenka and Cooper 1961, in Proctor, Hughes, and Fischman 1988, p. 458). Two workers exposed to an unknown concentration of tellurium hexafluoride generated by a 50-g leak of this substance in a laboratory developed garlic breath, a bluish-black discoloration of the webs of the fingers, and streaks on the neck and face; these individuals also reported fatigue. Both workers subsequently recovered (Blackadder and Manderson 1975, in Proctor, Hughes, and Fischman 1988, p.

Based on this evidence in humans and animals and by analogy with selenium hexafluoride, OSHA preliminarily concludes that tellurium hexafluoride causes pulmonary irritation, headaches, and dyspnea in exposed individuals. OSHA believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these effects and that establishing a PEL for tellurium hexafluoride of 0.02 ppm as an 8-hour TWA is necessary to substantially reduce this risk of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

CAS: 107-49-3; Chemical Formula: (C2H5)4P2O7 H.S. No. 2152

OSHA's current limit for tetraethyl pyrophosphate (TEPP) in general

industry, construction, and maritime is 0.05 mg/m3 as an 8-hour TWA, with a skin notation. There is no PEL for this substance in agriculture. The ACGIH TLV®-TWA for TEPP, which was set by analogy to parathion, is 0.05 mg/m3 (0.004 ppm), with a skin notation. NIOSH has no REL for this substance but concurs (Ex. 8-47) with the PEL being proposed by OSHA. The Agency is proposing a PEL of 0.05 mg/m3 as an 8-hour TWA, and a skin notation, for TEPP in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHAregulated sectors.

TEPP is a colorless to amber-colored liquid with a mild fruity odor. TEPP was one of the first organophosphate pesticides used in the United States. It is used as an insecticide and acaricide against aphids, spider mites, mealybugs, leaf hoppers, and thrips. TEPP has been replaced by other products in many of its applications. It was formerly used in the treatment of glaucoma, pediculosis of the eyelashes, and myasthenia gravis (HSDB 1989; Grant 1986, p. 893). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

TEPP is a cholinesterase inhibitor that is very toxic to warm-blooded animals by all routes of exposure. The oral LD₅₀ in rats is $500~\mu g/kg$, and the dermal LD₅₀ in the same species is $2400~\mu g/kg$ (RTECS 1989). Acutely poisoned animals exhibit hypersalivation, lacrimation, excessive perspiration, nasal discharge, miosis, breathing difficulties, nausea, diarrhea, and central nervous system effects including nervousness, ataxia, convulsions, and coma. Death is caused by respiratory failure or cardiac arrest (HSDB 1991).

In humans, TEPP is a powerful inhibitor of cholinesterase activity. The lowest concentration reported to be lethal in humans by ingestion is 309 μg/ kg (RTECS 1989). TEPP causes its toxic effects by inhibiting the activity of the enzyme cholinesterase, which causes, in turn, a buildup of acetylcholine at the synapses in the nervous and skeletal systems, smooth muscles, and secretory glands (Koelle 1963, Taylor 1985, and Hayes 1963, in Proctor, Hughes, and Fischman 1988, p. 464). TEPP causes ocular effects, including miosis, aching of the eyes, and blurring of distant vision, when it is applied to the eyelashes (as was formerly done to treat pediculosis of the eyelashes) or when it is absorbed in systemically toxic amounts (Grant 1986, p. 893). Volunteers given oral TEPP doses of 4 mg exhibited

a decrease in plasma cholinesterase activity to zero percent and in red blood cell cholinesterase activity to 60 percent of their pre-exposure values (Grob and Harvey 1949, in ACGIH 1986, p. 558). The onset of the signs and symptoms of TEPP poisoning may be delayed for as long as 12 hours, and the kinds of symptoms developed depend on the route of exposure. After inhalation, respiratory and ocular effects (wheezing, laryngeal spasms, blurred vision, miosis, and tearing) are first to occur. Cyanosis may also result from inhalation exposure to TEPP. Gastrointestinal effects occur after ingestion; these include anorexia, vomiting, diarrhea, and cramps. Skin absorption leads to localized sweating and muscular twitching (Koella 1963, Taylor 1985, in Proctor, Hughes, and Fischman 1988, p. 464). Severe TEPP poisoning by any route may lead to paralysis of the respiratory muscles and death. If the dose is not lethal, complete recovery may occur, although individuals may remain sensitive to organophosphorus poisoning for some time after recovery (Taylor 1985, in Proctor, Hughes, and Fischman 1988, p. 464). Repeated exposure to small doses of TEPP may have cumulative effects and lead to the signs and symptoms described above.

Based on this evidence in humans and animals, OSHA preliminarily concludes that TEPP causes cholinesterase inhibition, which is a material impairment of health. OSHA believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these exposure-related effects. The Agency believes that establishing a PEL of 0.05 mg/m3 as an 8-hour TWA, with a skin notation, is necessary to reduce the risk that agricultural workers will experience this material health impairment. Promulgation of this limit will make the PEL for TEPP consistent across all OSHA-regulated sectors.

THALLIUM (soluble compounds)
CAS: Varies with compound; Chemical
Formula: Varies with compound
H.S. No. 2159

OSHA's permissible exposure limit for soluble thallium compounds (measured as thallium) in general industry, construction, and maritime is 0.1 mg/m³; this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for these substances. There is no limit in agriculture. The ACGIH has an 8-hour TLV*-TWA of 0.1 mg/m³, with a skin notation, for the soluble thallium compounds. The ACGIH TLV* is based on analogy with other highly toxic

metals (ACGIH 1986, p. 569). There is no NIOSH REL, but NIOSH concurs (Ex. 8–47, Table N1) with the limit being proposed. OSHA is proposing a limit of 0.1 mg/m³ as an 8-hour TWA for soluble thallium compounds in agriculture. Promulgation of this limit will make the PEL for these substances consistent across all OSHA-regulated sectors.

Soluble thallium compounds include thallium sulfate, thallium acetate, and thallium nitrate, which are all colorless. odorless solids. Thallium sulfate is used as a poison for rodents, in semiconductor research, as a component of mineralogical solutions, in optical systems and photoelectric cells, and in low-range glass thermometers. Thallium nitrate is used as a reagent in analytical chemistry and to make green fire for signaling at sea. Thallium acetate is used in high specific gravity solutions to separate ore constituents by flotation (ACGIH 1986, p. 569; Merck 1983, p. 1325; Hawley's 1987, p. 1142).

Soluble thallium salts can cause hair loss and effects on the gastrointestinal, nervous, and circulatory systems of humans and animals. For thallium acetate, the oral LD50 in rats is 41 mg/kg; in mice, it is 35 mg/kg (RTECS 1991). For thallium nitrate, the oral LD50 in mice is 15 mg/kg (RTECS 1991). Thallium sulfate has oral LDsos in rats and mice of 16 and 15 mg/kg, respectively (RTECS 1991). Animals acutely poisoned by thallium sulfate show signs and symptoms that include restlessness, ataxia, and convulsive movements followed by paresis, tremor, dyspnea, loss of weight, hemorrhagic diarrhea, and death due to respiratory failure (Hayes 1982, p. 25). The primary functional disturbances to the nervous system caused by exposure to these compounds are hypotonia and ataxia: there are also pathological changes of the central and peripheral axons of the primary neurons (Kennedy and Cavanagh 1977, in Acta Neuropathol 39(1):81-88, as cited in HSDSB 1988). Rats fed thallium acetate at dietary levels of 30 ppm showed a marked depression in growth after 30 days; at this level, the animals lost all of their hair and displayed such histological changes as atrophy of the hair follicles and sebaceous glands (Clayton and Clayton 1981, p. 1921). Young rats given oral doses of 0.1 mg thallium acetate developed bone lesions, eye lesions, keratitis, cataracts, retrobulbar neuropathy, partial optic atrophy, and hormone dysfunction (Browning 1969, p. 319). Rats died suddenly at the end of 4 months after being administered daily oral doses of 0.45 mg/kg thallium acetate; the rats showed typical hair loss at the end of 6

weeks, in addition to loss of weight and appetite (Browning, Toxic Industrial Metals 2nd Ed. 1969, p. 319). Postmortem examination of rats receiving subacute doses of 10 to 15 mg/kg thallium acetate revealed significant changes in the kidneys, liver, and intestines (Herman and Bensch 1967, in Toxicology and Applied Pharmacology 10:199-222, as cited in Klaassen, Amdur, and Doull 1986, p. 491). Unspecified doses of orally or intravenously administered thallium sulfate caused depression of the cardiovascular and respiratory systems of dogs, cats, rats, rabbits, goats, and pigeons (Marmo et al. 1983, in Acta. Pharmacol. Sin. 4(2):119-122, in HSDB 1989 "Thallium Sulfate"). Administered to pregnant rats on days 12 to 14 of pregnancy, thallium sulfate caused fetotoxic and teratogenic effects at doses as low as 7.5 mg/kg (Toxicol. Appl. Pharmacol. 16:120, 1979). Rats exposed perinatally and postnatally to thallium sulfate in their drinking water showed modified vascular autonomic nervous system development (Rossi, Marrazzo, Berrino, DeSantis, Lisa, Susanna, Montanaro, Fici, and Marmo 1988, in Teratogenesis Carcin. Mutagen. 8(1):13-23).

In humans, exposure to the soluble thallium salts causes signs and symptoms such as nausea, vomiting, diarrhea, abdominal pain, and gastrointestinal hemorrhage (Paulson, Vergara et al. 1972, in Archives of Internal Medicine 129:100-103, as cited in Proctor, Hughes, and Fischman 1988, p. 473). These symptoms are often accompanied by peripheral neuritis, pain, weakness, paresthesias in the legs. tremor, and chest pain (Proctor, Hughes, and Fischman 1988, p. 471-472). The lowest lethal oral dose of thallium acetate in humans is estimated to be 12 mg/kg (Browning 1969, p. 317-322, as cited in Proctor, Hughes, and Fischman 1988, p. 471). The lowest toxic oral dose of thallium nitrate in humans is estimated to be 73 mg/kg, and the lowest lethal oral dose of thallium sulfate is believed to be 7 mg/kg (RTECS 1991, "Thallium nitrate, "Thallium sulfate"). A recent study (Dumitru and Kalantri 1990, in Muscle-Nerve 13(5):433-437) documents the serial conduction and electromyographic findings in a thallium-poisoned worker over a 24-month period. In this case, the plantar nerves of the foot demonstrated severe axonal loss first, and these nerves had not recovered 2 years later. Axonal loss subsequently occurred in the sural and perineal nerves as well, but they recovered within the 2-year follow-up period. A laboratory worker who had worked with thallium for 2

weeks developed acute thallium poisoning. His initial signs and symptoms included loss of consciousness, paresthesia of the finger tips and lips, malaise, and polyuria: later he developed respiratory paralysis, peripheral neuropathy, cerebellar ataxia, intellectual impairment, and cardiovascular abnormalities (Wainwright, Kox, House, Henry, Heaton, and Seed 1988, in Quarterly J. Med. 69(258):939-944). Chronic exposure to thallium salts can cause stomatitis, tremor, cachexia, polyneuropathy. alopecia, and emotional disturbance (Paulson et al. 1972, in Archives of Internal Medicine 129:100-103, as cited in Proctor, Hughes, and Fischman 1988. p. 472). Twelve of 15 workers using organic thallium salts over a period of 71/2 years experienced abdominal pain, fatigue, irritability, weight loss, and leg pain; 4 of these workers experienced loss of hair (Richerson 1958, in Ind. Med. Surg. 27:607). Three of these workers had albuminuria, and one had hematuria (Richerson 1958). In cases of mild chronic thallium intoxication, lymphocytosis and eosinophilia have been observed (J.C. Munch 1934, in American Medical Association I. 102:1929, as cited in Clayton and Clayton 1981, p. 1928).

Based on this evidence in humans and animals, OSHA preliminarily concludes that soluble thallium compounds cause alopecia and effects on the nervous, gastrointestinal, and circulatory systems. OSHA therefore believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these effects. OSHA believes that the proposed limit of 0.1 mg/m3, with a skin notation, for the soluble thallium compounds is necessary to significantly reduce these risks of material health impairment among agricultural workers. Promulgation of this limit will also make the PEL for these substances consistent across all OSHA-regulated sectors. THIONYL CHLORIDE CAS: 7719-09-7; Chemical Formula:

Cl2OS H.S. No. 1393

OSHA has no limit for thionyl chloride in construction, maritime, or agriculture. The ACGIH has a TLV .ceiling of 1 ppm for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the PEL being proposed. OSHA is proposing a 1-ppm ceiling PEL for thionyl chloride in construction, maritime, and agriculture. This is the limit recently established in general industry.

Thionyl chloride is a colorless to pale yellow liquid with a suffocating odor.

Thionyl chloride is used in the manufacture of pesticides, dyes, pharmaceuticals, and engineering plastics, as a chlorinating agent, and as a solvent in high energy density lithium batteries (ACGIH 1986, p. 572, HSDB

Thionyl chloride vapors are skin, eye, and mucous membrane irritants. probably because they form sulfur dioxide and hydrogen chloride on contact with moisture (ACGIH 1986/Ex. 1-3, p. 572). An inhalation exposure of 17.5 ppm proved lethal to cats within 20 minutes (Sax 1979/Ex.1-866).

OSHA's exposure limit for thionyl chloride in general industry is based on the exposure limits for the decomposition products (hydrogen chloride and sulfur dioxide) of thionyl chloride when this substance is mixed with water. The reaction of one mole of thionyl chloride with water produces two moles of hydrogen chloride and one of sulfur dioxide, so that 1 ppm of thionyl chloride can be shown to produce a total irritant gas concentration of 3 ppm. The exposure limit for hydrogen chloride is 5 ppm as a ceiling limit; for sulfur dioxide, the limit is an 8-hour TWA of 2 ppm. Thus, OSHA believes that the proposed ceiling limit for thionyl chloride will prevent the irritant effects of its reaction products.

In construction, maritime, and agriculture, the Agency is proposing a ceiling limit of 1 ppm for thionyl chloride on the basis of analogy to the irritation potential of hydrogen chloride and sulfur dioxide and to achieve consistency in OSHA limits in all regulated sectors. OSHA preliminarily concludes that this limit will protect workers in these sectors from the significant risk of eye, skin, and mucous membranes irritation, which constitutes a material health impairment that is associated with exposure to this substance.

TRIBUTYL PHOSPHATE CAS: 126-73-8; Chemical Formula: (C4He)aPO4 H.S. No. 1402

In construction and maritime, OSHA s current PEL for tributyl phosphate is 5 mg/m3 as an 8-hour TWA. There is no PEL in agriculture. The ACGIH has a 2.5mg/m3 TLV9-TWA for tributyl phosphate. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 2.5 mg/m3 for tributyl phosphate in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry.

Tributyl phosphate is a colorless liquid. It is used as an anti-foaming agent, a plasticizer, a hydraulic fluid, a heat-exchange medium, and in the solvent extraction of metals (RTECS 1991).

Tributyl phosphate's toxicity affects the skin, mucous membranes, lungs, and central nervous system, and this substance is also a cholinesterase inhibitor. The oral LD50 in rats is 3000 mg/kg, and the LC50 in mice is 1300 mg/ m3 for an unspecified time (RTECS 1991). A paper by Smyth and Carpenter (1944/ Ex. 1-374) reported that contact with liquid tributyl phosphate caused severe eye injury and skin irritation when tested in rabbits. Chambers and Casida (1967/Ex. 1-305) found that mice injected with 1 g/kg tributyl phosphate intraperitoneally became paralyzed. A study by Vandekar (1957/Ex. 1-498) in which mice were given tributyl phosphate by gavage revealed that a dose of 80 mg/kg resulted in a one-hour period of anesthesia, and a dose of 100 mg/kg resulted in 8 to 10 minutes of anesthesia, followed by respiratory failure and death. Administered intraperitoneally to rats, tributyl phosphate inhibited cholinesterase activity and stimulated plasma betaglucuronidase activity (Suzuki, Kikuchi, Kato et al. 1977/Ex. 1-1170). This substance did not exhibit mutagenic activity in bacterial or fruit fly assays (Hanna and Dyer 1975/Ex. 1-485).

Nausea and headache were reported by workers exposed to levels of 15 mg/ m³ of tributyl phosphate (Mastromatteo 1964b, as cited in ACGIH 1986/Ex. 1-3, p. 591). In contact with the skin, tributyl phosphate causes irritation (HSDB 1991).

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 2.5 mg/m3 for tributyl phosphate in construction, maritime, and agriculture. OSHA preliminarily concludes that this limit will protect workers in these sectors against the significant risk of paralysis, anesthetic effects, and skin or eye irritation, all of which constitute material impairments of health that are associated with occupational exposure to tributyl phosphate. The Agency believes the proposed PEL is necessary to substantially reduce these risks. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. TRICHLOROACETIC ACID CAS: 76-03-9; Chemical Formula:

CCl₃COOH H.S. No. 1404

In construction, maritime, and agriculture, OSHA has no PEL for trichloroacetic acid. The ACGIH has an 8-hour TLV*-TWA of 1 ppm for this

substance. There is no NIOSH REL. In construction, maritime, and agriculture, OSHA is proposing a PEL of 1 ppm as an 8-hour TWA, and NIOSH concurs (Ex. 8-47, Table N1) that this limit is appropriate. This is the limit recently established for trichloroacetic acid in general industry.

Trichloroacetic acid is used in medicine, as a decalcifier and fixative in microscopy, and as a chemical intermediate (HSDB 1991). The oral LD₅₀ for trichloroacetic acid in rats is 5 g/kg (RTECS 1991). Studies on mice conducted by NIOSH (1984, as cited in ACGIH 1986/Ex. 1–3, p. 592) established that the oral LD₅₀ for this species is 4.97 g/kg, and that a 500-mg/kg dose was fatal when administered intraperitoneally. In contact with the skin of rabbits, trichloroacetic acid caused mild irritation; instilled into the eyes, it caused severe irritation (RTECS 1991)

Although corrosive, trichloroacetic acid is not readily absorbed through the skin (ACGIH 1986/Ex. 1–3, p. 592). Contact of the skin with this substance for 1 hour or more causes burns; splashed into the eye, it causes severe pain and may cause permanent injury (HSDB 1991).

Based on this evidence, OSHA is proposing an 8-hour TWA limit of 1 ppm for trichloroacetic acid in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors from the significant risk of skin and eye irritation, which are material impairments of health that are associated with occupational exposure to this substance. OSHA believes that the proposed limit will substantially reduce this risk. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. 1,1,2-TRICHLOROETHANE

CAS: 79–00–5; Chemical Formula: CHCl₂CH₂Cl

H.S. No. 2162 In general industry, construction, and maritime, OSHA has an 8-hour TWA of 10 ppm, and a skin notation, for 1,1,2trichloroethane. The Agency has no PEL for this substance in agriculture. The ACGIH TLV*-TWA for 1,1,2trichloroethane, which was set by analogy to chloroform, is 10 ppm, with a skin notation. Although NIOSH considers this substance a potential human carcinogen, NIOSH concurs (Ex. 8-47) with the limit being proposed by OSHA for this substance. The Agency is proposing an 8-hour TWA PEL of 10 ppm, and a skin notation, for 1,1,2trichloroethane in agriculture.

Promulgation of this limit will make the PEL for 1,1,2-trichloroethane consistent across all OSHA-regulated sectors.

1,1,2-Trichloroethane is a colorless, nonflammable liquid with a pleasant, sweet odor. It is used as a chemical intermediate in the production of 1,1-dichloroethylene (vinylidene chloride) and as a solvent for fats, resins, adhesives, chlorinated rubbers, polyesters, and waxes (ACGIH 1986, p. 596; HSDB 1989).

In animals, exposure to 1.1.2trichloroethane causes central nervous system depression and damage to the liver and kidneys. This substance is also a mild irritant of the eyes, mucous membranes, and skin; in mice, it is a liver carcinogen. The oral LD50 in rats is 830 mg/kg, and the lowest lethal concentration in the same species is 2000 ppm for 4 hours; the dermal LD50 in rabbits is 5377 mg/kg (RTECS 1989). Although 1,1,2-trichloroethane is not a severe skin irritant, it causes defatting of the skin on repeated contact. Absorption through the skin has been shown to cause toxic effects, including liver and kidney injury, in both rabbits and guinea pigs (Jakobson, Holmberg, and Wahlberg 1977, in Clayton and Clayton 1981, p. 3511). Instilled into the eves of rabbits, this substance caused a mild degree of irritation (RTECS 1989). Half of the female rats exposed to a 250ppm concentration of 1.1.2trichloroethane for 7 hours died and showed marked liver and kidney damage at autopsy; when the exposure period was shortened to 4 hours, the animals survived the exposure but still showed liver and kidney necrosis at autopsy. Rats exposed to 250 ppm for 2 hours, however, did not exhibit liver or kidney damage at autopsy (Clayton and Clayton 1981, p. 3511). Animals dosed orally also demonstrated liver and kidney damage at autopsy (Gehring 1968; Watrous and Plaa 1972, in Clayton and Clayton 1981, p. 3511). A significant increase in hepatocellular carcinomas occurred in mice given 195 or 390 mg/ kg/day 1,1,2-trichloroethane by gavage for 78 weeks. The incidence of adrenal pheochromocytomas was also increased in the high-dose female mice. No statistically significant increase in the incidence of tumors was seen in rats given up to 92 mg/kg/day 1,1,2trichloroethane (National Cancer Institute 1978, in Proctor, Hughes, and Fischman 1988, p. 486). The International Agency for Research on Cancer has concluded that the evidence for the carcinogenicity of 1,1,2-trichloroethane in animals is limited (IARC 1987, Suppl. 7, p. 73).

In humans, exposure to low (not further specified) concentrations of 1,1,2trichloroethane has narcotic effects and causes eye and mucous membrane irritation (IARC 1979, Vol. 20, p. 540). Chronic exposure causes fat deposition in the kidney and lung damage (IARC 1979, Vol. 20, p. 540). Based on animal data, the probable lethal oral dose of 1,1,2-trichloroethane in humans is estimated to be 50 to 500 mg/kg (Parmeggiani 1983, p. 2214). Prolonged or repeated contact of the skin with this substance causes defatting and may cause dermatitis (Clayton and Clayton 1981, pp. 3510-3513).

Based on this evidence, OSHA preliminarily concludes that exposure to 1,1,2-trichloroethane potentially causes central nervous system depression and liver and kidney damage. OSHA believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these effects. OSHA believes that establishing a PEL of 10 ppm as an 8-hour TWA, with a skin notation, is necessary to reduce the risk of these material health impairments. Promulgation of this limit will also make OSHA's PEL for this substance consistent across all OSHA-regulated sectors.

TRIMETHYLAMINE
CAS: 75-50-3; Chemical Formula:
(CH₃)₃N
H.S. No. 1411

In construction, maritime, and agriculture, OSHA has no PEL for trimethylamine. The ACGIH has a 10-ppm TLV*-TWA and a 15-ppm TLV*-STEL. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limits being proposed. OSHA is proposing PELs of 10 ppm as an 8-hour TWA and 15 ppm as a 15-minute STEL in construction, maritime, and agriculture. These are the limits recently established for trimethylamine in general industry.

Trimethylamine has a pungent, fishy odor and is a gas at room temperature. Trimethylamine is used as an insect attractant, a warning agent for natural gas, a flotation agent, in organic synthesis, and in the manufacture of quaternary ammonium compounds (ACGIH 1986, p. 607; Merck 1983, p. 1388).

Trimethylamines are irritants of the eyes, mucous membranes, and respiratory tract. The lowest lethal concentration in rats is 3500 ppm for 4 hours (RTECS 1991). The damage done to the eyes of animals when trimethylamine is instilled into the conjunctival sac ranges from severe irritation to permanent damage, depending on the strength of the solution (Grant 1986, p. 952). Contact of

the skin or eyes with this substance also causes burns and irritation in humans (Sittig 1985, p. 896). A student splashed in the eye with trimethylamine showed loss of the corneal epithelium; however, 4 weeks later, recovery was complete (Grant 1986, p. 952).

In construction, maritime, and agriculture, OSHA is proposing an 8hour TWA limit of 10 ppm and a 15minute STEL of 15 ppm for trimethylamine. The Agency preliminarily concludes that these limits will protect workers in these sectors from the significant risk of eye, mucous membrane, and upper respiratory tract irritation, which constitute material impairments of health that are caused by occupational exposure to this substance. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

n-VALERALDEHYDE CAS: 110-62-3; Chemical Formula: CH₃(CH₂)₃CHO H.S. No. 1420

In construction, maritime, and agriculture, OSHA has no limit for n-valeraldehyde. The ACGIH TLV*-TWA is 50 ppm. NIOSH has no REL but concurs (Ex. 8–47, Table N1) with the proposed PEL. OSHA is proposing a PEL of 50 ppm as an 8-hour TWA for n-valeraldehyde in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry.

Valeraldehyde is a colorless liquid that is used as a flavoring agent and rubber accelerator, and in resin chemistry (ACGIH 1986, p. 619).

n-Valeraldehyde's toxic effects include both skin and eye irritation. Animal studies showed n-valeraldehyde to be severely irritating when applied to guinea pig skin and to rabbits' eyes (Fassett, as cited in ACGIH 1986/Ex. 1-3. p. 619). The dermal LD50 in guinea pigs exceeds 20ml/kg (Fassett, as cited in ACGIH 1986/Ex. 1-3, p. 619). A series of studies of the relative acute inhalation toxicity of 13 aliphatic saturated and unsaturated aldehydes in mice, guinea pigs, and rabbits showed that valeraldehyde was relatively nontoxic systemically (Salem and Cullumbine 1960/Ex. 1-360).

In construction, maritime, and agriculture, OSHA is proposing a 50-ppm 8-hour TWA limit for n-valeraldehyde. The Agency preliminarily concludes that this limit will protect workers in these sectors from the significant risk of severe eye and skin irritation associated with occupational exposure to this substance. OSHA believes that this limit will

substantially reduce this risk. In addition, promulgation of this limit will make OSHA's PEL for valeraldehyde consistent across all regulated sectors.

m-XYLENE ALPHA, ALPHA'-DIAMINE CAS: 1477–55–0; Chemical Formula:

C₆H₄(CH₂NH₂)₂

H.S. No. 1432

In construction, maritime, and agriculture, OSHA has no exposure limit for this substance. The ACGIH has a TLV*-ceiling of 0.1 mg/m³ and has added a skin notation to indicate that substantial percutaneous absorption can occur through the eyes, mucous membranes, and skin. NIOSH has no REL but concurs (Ex. 8–47, Table N1) with the proposed limit. OSHA is proposing a PEL of 0.1mg/m³ as a ceiling for m-xylene alpha, alpha'-diamine in construction, maritime, and agriculture. This is the limit recently established for this substance in general industry.

m-Xylene alpha, alpha'-diamine (MXDA) is a colorless liquid. This substance is used as a curing agent for epoxy resins, as a source of m-Xylene disocyanate, and in the manufacture of plastics, textiles, and rubber (ACGIH 1986, p. 638; Hazardous Substance Fact Sheet 1986, p. 1).

Animal studies have demonstrated that MXDA is strongly irritating to the skin. When applied to the skin of rabbits, MXDA caused severe irritation; 50 mg applied to the eyes of rabbits also caused severe injury (RTECS 1991). The oral LD50 in rats is 930 mg/kg, and the LC50 in the same species is 700 ppm for 1 hour (RTECS 1991). The dermal LD50 in rabbits is 2 g/kg (RTECS 1991). Rats exposed to concentrations of MXDA ranging from 1.74 to 6.04 mg/liter even for one hour sustained liver, kidney, and lung damage, as determined at necropsy. One study showed mild sensitization when MXDA was applied to guinea pig skin, but this effect was not observed in a second study (Sherwin-Williams Company 1978, as cited in ACGIH 1986/ Ex. 1-3, p. 638).

Based on this evidence, OSHA preliminarily concludes that a ceiling limit of 0.1 mg/m3 and a skin notation are necessary to protect workers in construction, maritime, and agriculture from the significant risk of skin irritation, percutaneous absorption, and the potential systemic effects associated with exposure to MXDA. The Agency considers these effects material impairments of health. OSHA believes that the proposed limit will substantially reduce this significant risk. In addition, promulgation of this limit will make OSHA's PEL for MXDA consistent across all regulated sectors.

XYLIDINE
CAS: 1300-73-8; Chemical Formula:
(CH₃)₂C₆H₅NH₂
H.S. No. 1433

In construction and maritime, OSHA's limit for xylidine is 5 ppm as an 8-hour TWA, with a skin notation. There is no PEL in agriculture. The ACGIH has a TLV*-TWA of 2 ppm, also with a skin notation. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. In construction, maritime, and agriculture, OSHA is proposing an 8-hour TWA PEL of 2 ppm, and a skin notation, for xylidine. This is the limit recently established for this substance in general industry.

Xylidine is a pale yellow to brown liquid. Commercial xylidine is a mixture of isomers. Xylidine is primarily used in the manufacture of dyes. It is also used in organic synthesis and pharmaceuticals (Merck 1983, p. 1448;

ACGIH 1986, p. 639 (88)).

Several studies indicate that the current PEL for xylidine in construction and maritime is insufficient to protect workers against hepatotoxic and other adverse effects, and agricultural workers are currently without any protection against exposure. A paper by von Oettingen, Neal, Sievers et al. [1947, as cited in ACGIH 1986/Ex. 1-3, p. 639) reported liver damage in dogs, rats, cats, and mice repeatedly exposed to 45 ppm xylidine for seven hours per day for a period of 20 to 40 weeks; these exposures also caused death in dogs, cats, and mice. Treon, Sigmon, Wright et al. (1950/Ex. 1-533) noted cardiac, liver, and kidney damage in autopsies of

animals fatally exposed at the following doses: cats, 17 ppm; guinea pigs, 50 ppm; and rabbits, 60 ppm; cyanosis was also observed in these animals.

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 2 ppm, and a skin notation, for xylidene in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors from the significant risk of exposure-related cardiac, kidney, and liver damage, all of which constitute material health impairments. OSHA believes the proposed PEL is necessary to substantially reduce these risks. In addition, promulgation of this limit will make OSHA's PEL for xylidine consistent across all regulated sectors.

Preliminary Conclusions for This Group of Substances

Based on the evidence described above, OSHA preliminarily concludes that exposure to any of the substances included in this category places workers in construction, maritime, and agriculture at significant risk of material health impairment and functional incapacity. The adverse health consequences of exposure to these chemicals include neuropathies, skin and respiratory tract irritation, kidney and liver damage, and gastrointestinal disorders, all of which constitute material health impairments within the meaning of the Act. OSHA preliminarily concludes, based on the toxicological evidence, that the new or revised limits being proposed for these hazardous substances will substantially reduce these significant occupational risks for

workers in these sectors. In addition, promulgation of the proposed limits will make OSHA's PELs for these substances consistent across all regulated sectors.

 Substances for Which Proposed Limits Are Based on Avoidance of Biochemical/Metabolic Effects

Introduction

One basis for establishing exposure limits is to prevent toxic substances from interfering with the normal metabolism or biochemistry of the body. A total of 31 substances in this rulemaking belong in the category of biochemical or metabolic toxins. Table C12-1 shows these substances and their CAS and HS numbers. Table C12-1 also shows the current PELs for these substances in construction and maritime, the ACGIH TLV*s (1987-1988), the NIOSH RELs (where these apply), and the limits OSHA is proposing to establish in construction, maritime, and agriculture. Promulgation of these PELs will make OSHA's limits for these biochemical/metabolic toxins consistent across all OSHA-regulated sectors.

Description of the Health Effects

The compounds shown in Table C12-1 are further divided into the following sub-classes, based on their mechanism of action:

- Substances that are cholinesterase inhibitors;
- Substances that interfere with the oxygen-carrying capacity of the blood;
- Substances with Antabuse-like effects.

2168 Warfarin	81-81-2	0.1 mg/m³ TWA	0.1 mg/m³ TWA		0.1 mg/m³ TWA

*OSHA's PELs do not currently apply in Agriculture; OSHA's TWA limits are for 8-hour exposures; its STELs are for 15 minutes unless otherwise specified; and its ceilings are peaks not to be exceeded for any period of time.

**The ACGIH TLV®—TWA is for an 8-hour exposures; its STELs are 15-minutes limits not to be exceeded more than 4 times in any working day, with a minimum of

60 minutes between successive STEL exposures; and its ceilings are peaks not to be exceeded for any period of time.

""NIOSH TWA limits are for 10 hour/day, 40 hour/week exposures unless otherwise specified, and its ceilings are peaks not to be exceeded for any period of time unless a duration is specified in parentheses.

The disruption of metabolic processes by toxic substances, if severe enough, results in potentially dangerous effects on the neurological, cardiovascular, and respiratory systems. The adverse health consequences caused by exposure to chemicals having cholinesterase inhibition effects range from wheezing, nausea, vomiting, and confusion to respiratory failure, coma, and death. Table C12-2 shows the primary biochemical/metabolic effects associated with occupational exposure to the substances in this group of toxins.

If exposure has localized rather than systemic effects, the signs and symptoms of cholinesterase inhibition can include sweating, blurred vision, and constriction of the bronchial tubes. Substances that interfere with the ability of the blood to carry oxygen cause a broad range of symptoms, including fainting, loss of consciousness, rapid heartbeat, headache, nausea, coma, and death. Carbon monoxide (CO) is the best-known substance in this category of chemicals, and exposure to CO is common throughout the

construction, maritime, and agriculture industries.

The Antabuse-like effects associated with exposure to three of the chemicals in this group-disulfiram, cyanamide, and calcium cyanamide-include facial flushing, nausea, and a racing heartbeat. However, these effects are manifested only if the exposed individual has ingested alcohol. The three chemicals in this subgroup cause this effect by inhibiting aldehyde dehydrogenase activity, which is involved in the biotransformation of alcohol.

For chemicals that cause systemic toxicity in animals and/or humans, the grossly observable signs and symptoms of intoxication are usually secondary to the interaction of the chemical with a molecular target. In other words, the chemical interacts with (binds with or modifies) an endogenous molecular constituent (protein, nucleic acid, lipid, etc.) in the target tissue. The result of the interaction is ordinarily a modification or elimination of the normal function of the specific molecular constituent which, if sufficiently severe, may lead to secondary effects within the affected cells and/or tissues. It is possible for a number of molecules to be affected by the toxic chemical without there being any overt manifestation of toxicity. In other words, there is an apparent noeffect level governing the overt manifestation of toxicity, although there are usually metabolic effects at levels below those that cause overt effects.

For chemicals for which the molecular target is known and for which methods are available to detect the altered molecular target, it is possible to use the measure of altered biochemical function as a sensitive indicator of exposure to the chemicals at levels below those that cause grossly observable signs and symptoms of poisoning. For other classes of chemicals, studies in animals and/or humans have shed light on the biochemical basis of their toxicity. For some of these classes of chemicals, it is possible to base limits for human exposure on biochemical, metabolic, or pharmacologic indicators of their interaction with molecular targets rather than on grossly visible signs and symptoms of adverse systemic effects.

Substances that are cholinesterase inhibitors. A number of organophosphate and carbamate insecticides produce acute toxicity in humans through inhibition of acetylcholinesterase at cholinergic synapses in the central and peripheral

nervous systems. Many of the substances in this group have this effect. This inhibition causes an accumulation of acetylcholine at the effector sites and elicits signs and symptoms consistent with excessive cholinergic activity. These include bronchoconstriction; increased bronchial secretions, salivation, and lacrimation; nausea; vomiting; cramps; constriction of the pupils; muscular weakness; and cardiac irregularities. If sufficiently severe, acetylcholinesterase inhibition may cause coma, irreversible CNS damage, and death.

The mechanisms by which carbamates and organophosphates inhibit acetyl-cholinesterase differ. In general, carbamates form a noncovalently bound complex with the enzyme, while most organophosphates bind covalently with the enzyme. The net result, inactivation of the enzyme, is similar for both groups. In either case, the inhibition is usually reversible. The carbamate-cholinesterase complex dissociates to regenerate the active enzyme, while cholinesterase inactivated by organophosphates is, replaced by the de novo synthesis of active enzyme. Therefore, unless the inhibition is sufficiently severe to cause brain damage or death, the manifestations of acute toxicity are reversible, and poisoned individuals recover without sequelae. A significant proportion of endogenous cholinesterase activity may be inhibited before the overt manifestations of intoxication appear. The fraction of total cholinesterase activity that can be inhibited without the development of signs and symptoms of toxicity varies from individual to individual and also appears to depend on the intensity and duration of exposure. The lack of warning signs at low levels of exposure increases the need to set exposure limits at levels that will protect those

individuals who do not readily manifest

the symptoms and signs of toxicity from experiencing the subclinical effects of exposure.

Substances that interfere with the oxygen-carrying capacity of the blood. Several compounds in this section produce their immediate toxicity in humans by altering the ability of hemoglobin in the red blood cells to bind, transport, and release oxygen. Perhaps the best studied of these is carbon monoxide. Carbon monoxide binds to hemoglobin with a greater affinity than does oxygen. It also alters the dissociation characteristics for the oxygen-hemoglobin complex. The overall effect is to reduce the oxygencarrying capacity of the blood. Also included in this overall category of compounds is a group of aromatic amines and nitro compounds that react with hemoglobin in the blood to reduce it to methemoglobin. Methemoglobin will not bind with oxygen and therefore is not an effective carrier of oxygen.

Because these compounds reduce the ability of the blood to transport oxygen, the overt signs and symptoms of acute toxicity are those of tissue anoxia, i.e., neurobehavioral disturbances, dizziness, cardiac irregularities, cyanosis, unconsciousness, and death. The severity of the symptoms is a function of the degree to which the oxygen-carrying capacity of the blood has been depleted and of the state of the exposed individual's health. In the case of carbon monoxide, individuals with pre-existing cardiovascular disease or healthy individuals engaged in physical labor may be placed at increased risk when more than 5 percent of their hemoglobin is bound to carbon monoxide.

In the cases of both carbon monoxide and the methemoglobin-forming compounds, the primary effect (i.e., formation of carboxyhemoglobin or methemoglobin) is reversible. In the absence of additional carbon monoxide exposure, carboxyhemoglobin dissociates to carbon monoxide and fully functional hemoglobin.

Methemoglobin can be reoxidized to hemoglobin by endogenous mechanisms, but the major recovery mechanism is via the synthesis of new hemoglobin.

Substances with Antabuse-like effects. The ingestion of alcoholic beverages following exposure to disulfiram, cyanamide, or calcium cyanamide results in a characteristic syndrome consisting of flushing of the face, nausea, vomiting, hypotension, and increased heart rate. If exposure is particularly severe, the reaction may trigger convulsions, cardiac arrhythmias, or heart attacks; in some cases, such exposures have caused death. In the vast majority of less severe cases, the reaction is fully reversible, although the symptoms are temporarily completely disabling. Disulfiram (Antabuse) is used therapeutically in the treatment of chronic alcoholism; employees who are currently being treated with disulfiram for alcoholism are therefore at particularly high risk if they are also occupationally exposed to these substances that cause Antabuse-like effects. These compounds do not cause any signs or symptoms of toxicity in the absence of alcohol ingestion unless exposure levels are far above those that trigger the alcohol-induced response.

Dose-Response Relationships and Biochemical/Metabolic Effects

Substances that are cholinesterase inhibitors. Typically, the cholinesterase inhibition potential of a compound is assessed by measuring plasma cholinesterase activity in the treated organism. Data from experiments in animals and limited data from human clinical trials indicate that the percentage of basal plasma cholinesterase activity decreases with increasing dose and that the doseresponse curve is S-shaped. Because there is interindividual variation in this relationship, the dose-response curve for a population exposed to a cholinesterase inhibitor would be expected to be much shallower in slope and to have longer tails than the doseresponse curve for any single individual.

The relationship between the doseresponse curve for plasma
cholinesterase inhibition and the doseresponse curves for more direct
indicators of clinical intoxication, such
as acetyl cholinesterase activity in the
CNS or the actual appearance of signs of
intoxication, is not known. Evidence
suggests that there is considerable
interindividual variability in these
relationships. Some individuals may be
free of the symptoms and signs of

intoxication when their plasma cholinesterase levels have been inhibited by as much as 90 percent, while others may experience symptoms after only a small decrease in plasma cholinesterase activity. Because of this wide variation in response, any exposure limit should be set with individual variability in mind.

Substances that interfere with oxygen transport. Both carboxyhemoglobin and methemoglobin formation exhibit a classical sigmoidal dose-response relationship in relation to exposure to carbon monoxide or methemoglobinforming compounds. The loss in the oxygen-carrying capacity of the blood is a function of the intensity and duration of exposure. As stated above, the majority of healthy individuals can tolerate some reduction in the oxygencarrying capacity of their blood without experiencing symptoms of overt toxicity. However, there is great interindividual variability in the degree of decreased oxygen-carrying capacity that can be tolerated without apparent ill effect. Individuals with pre-existing anemia or with high carboxyhemoglobin levels as a result of other environmental exposures (e.g., smoking) may already be at or above the level at which they will display the signs or experience the symptoms of tissue anoxia. For these individuals, even a small incremental decrease in the oxygen-carrying capacity of the blood can have serious consequences.

Substances causing Antabuse-like effects. The dose-response characteristics of disulfiram, cyanamide, and calcium cyanamide follow the usual S-shaped curve. The proposed rule's limits for the substances in this group have been set at levels below those associated with the Antabuse effect in workers ingesting alcohol either during or after work.

The following paragraphs describe the Agency's preliminary findings with respect to these substances that cause biochemical/ metabolic disturbances. The discussions below also illustrate the risk of material health impairment associated with exposure to these substances.

ANILINE (AND HOMOLOGS) CAS: 62-53-3; Chemical Formula: C₈H₈NH₂ H.S. No. 1025

OSHA's 8-hour TWA permissible exposure limit for aniline in construction and maritime is 5 ppm, with a skin notation. There is no limit in agriculture. The ACGIH-recommended 8-hour TLV*-TWA is 2 ppm, with a skin notation. NIOSH has no REL but concurs (Ex. 8-47, Table N6A) with the

limit being proposed. OSHA is proposing an 8-hour TWA PEL of 2 ppm, and a skin notation, for aniline in construction, maritime, and agriculture; this is the limit recently established in general industry.

When first distilled, aniline is an oily, colorless liquid that darkens on exposure to air; it has a characteristic odor. Aniline and its homologs are used in the manufacture of resins, varnishes, perfumes, shoe blacks, solvents, vulcanizing agents, inks, paint removers. explosives, herbicides, dyes, lacquers, wood stains, corrosion inhibitors, and photographic chemicals. Aniline also finds use as a chemical intermediate and laboratory reagent (HSDB 1990; ACGIH 1986, p. 30). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Aniline causes methemoglobinemia on acute exposure and anemia, weight loss, and cutaneous lesions on chronic exposure. Aniline also causes cancer in animals. The LC₅₀ in mice is 175 ppm for 7 hours, and the lowest toxic concentration in rats is 250 ppm for 4 hours (1990). The dermal LD50 in rabbits is 820 mg/kg (RTECS 1990). Rats were given single oral doses of aniline (500, 622.9, 775.9, 866.0, 966.6, 1204.1, or 1500.0 mg/kg) in a recent acute toxicity study (EPA 1986, Doc. #86-870001696, OTS). Within 14 days of dosing, 1 rat in the 622.9 mg/kg group, 6 rats in the 775.9 mg/kg group, 7 rats in the 866.0 mg/kg group, 9 rats in the 1204.1 mg/kg group, and all rats in the 1500 mg/kg group had died. Oral LD50s of 930 mg/kg for males and 780 mg/kg for females were established in this study. Acutely poisoned animals showed cyanosis, tremors, tachypnea, lacrimation, and coma before death. Rats exposed to 5 ppm of aniline for 6 months showed a slight increase in methemoglobinemia (Oberst, Hackley, and Comstock 1956/ Ex. 1-685). Guinea pigs, dogs, and mice exposed to aniline on the same regimen showed no effects (Oberst, Hackley, and Comstock 1956/Ex. 685). Rats exposed chronically to aniline hydrochloride developed spleen hemangiosarcomas; dietary levels were 10, 30, or 100 mg/kg. Treated rats showed splenic tumors and fibrosarcomas and sarcomas of multiple body organs (NCI1 1987a/Ex. 1-1118).

Occupational aniline poisoning was a relatively common occurrence in earlier years (ACGIH 1986/Ex. 1-3, p. 30). The early limits for aniline were set to guard against acute toxicity manifested as cyanosis (Henderson and Haggard 1943i, as cited in ACGIH 1986/Ex. 1-3, p. 30).

Cirrhosis and chronic CNS effects were also reported in early studies (Holstein 1955/Ex. 1-913; von Oettingen 1941/Ex. 1-874). Skin absorption occurs when aniline vapor contacts the skin (Dutkiewicz 1962, as cited in ACGIH 1986/Ex. 1-3, p. 30). Early studies suggested that less than full-shift exposure to concentrations of aniline vapor ranging from 7 to 53 ppm caused mild symptoms, while one-hour inhalation exposures to concentrations in the range of 100 to 160 ppm caused severe effects (Henderson and Haggard 1943i, as cited in ACGIH 1986/Ex. 1-3, p. 30). A NIOSH-sponsored study conducted in 1986 reports that altering the workshift from five 8-hour days to four 12-hour days increased the toxicity associated with exposure to aniline at 50 or 150 ppm (Kim, YC and Carlson GP 1986, in Fund. Appl. Toxicol. 7(1):144-152). Aniline-induced methemoglobinemia was cumulative in both 8-hour and 12-hour workers exposed to 50 ppm, but this effect was more severe in those working the longer shift. Methemoglobin levels in the blood returned to normal after overnight recovery in the 8-hour group but did not recover in the workers working the 12hour shift. Two poisoning incidents attributable to aniline absorption through the skin have been reported; in both cases, the onset of symptoms was delayed for 2 to 4 hours. Both victims became weak, developed headaches. became deeply cyanotic, and collapsed; after treatment, recovery was complete (Gosselin, Smith, and Hodge 1984, p. III-

Based on this evidence, OSHA preliminarily concludes that aniline causes methemoglobinemia in humans by inhalation and skin absorption. Accordingly, OSHA is proposing an 8hour TWA of 2 ppm for aniline, and a skin notation, in construction, maritime, and agriculture. The Agency believes that this limit will protect workers in these sectors from the significant occupational risk of methemoglobinemia, which constitutes a material impairment of health. Promulgation of this limit will also make OSHA's PEL for aniline consistent across all regulated sectors.

CALCIUM CYANAMIDE CAS: 158-62-7; Chemical Formula: CaNC=N

H.S. No. 1058

OSHA has no limit for calcium cyanamide in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 0.5 mg/m³ for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed, which is 0.5 mg/m³ as an 8-

hour TWA. This is the limit recently established for calcium cyanamide in general industry.

Calcium cyanamide is a white-to-gray, crystalline solid. Calcium cyanamide is used as a fertilizer, an herbicide, and a defoliant for cotton plants; it also finds use as a chemical intermediate (Clayton and Clayton 1981, p. 4856). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Calcium cyanamide causes parasympathetic overactivity in overexposed humans and animals; in humans, exposure may cause intense cutaneous and mucosal flushing, headache, vertigo, tachypnea, hypotension, and profound shock (Gosselin, Smith, and Hodge 1984, p. II-351). In rats, the oral LD50 is 158 mg/kg (RTECS 1990). Skin and eye irritation have been reported in rats and rabbits, with significant irritation occurring when 100 mg of calcium cyanamide is placed directly into the eyes of rabbits (Martin 1975, as cited in ACGIH 1986/ Ex. 1-3, p. 91). Severe skin irritation developed in rabbits when a paste of this substance was applied to the shaved abdominal skin for 24 hours (Martin 1975, as cited in ACGIH 1986/ Ex. 1-3, p. 91). Two of five animals died when the dose was 10 g/kg, but all

survived a dose of 5 g/kg.

Most cases of industrial calcium cyanamide poisoning involve primary skin irritation or sensitizing dermatitis. Skin irritation develops in the form of an erythematous rash over the surfaces of the body that are exposed to the substance or those body surfaces irritated by clothing or perspiration. Some individuals develop a macular rash on exposure, and this may progress to the weeping stage. In addition, exposed workers may develop temporary vasomotor disturbances of the upper body, with susceptibility increasing with alcohol intake (Fassett 1963d, as cited in ACGIH 1986/Ex. 1-3,

The fatal dose in humans is estimated to be 40 to 50 grams. Calcium cyanamide is used medically for its Antabuse-like effect, and the maintenance dose in adults is between 50 and 100 mg/day (Hald, Jacobsen, and Larson 1952/Ex. 1–905). One death has been caused by the ingestion of alcohol when the patient was on calcium cyanamide alcohol aversion therapy (Gosselin, Smith, and Hodge 1984, p. II–351).

Based on this evidence, OSHA is proposing an 8-hour TWA PEL of 0.5 mg/m³ for calcium cyanamide. The Agency believes that this limit is necessary to substantially reduce the significant risks of material health impairment in the form of eye and skin irritation, sensitizing dermatitis, and the occurrence of Antabuse-like effects in workers in construction, maritime, and agriculture. Promulgation of this limit will also make the PEL for calcium cyanamide consistent across all OSHA-regulated sectors.

CARBOFURAN
CAS: 1563-66-2; Chemical Formula:
C₁₂H₁₅NO₃

H.S. No. 1068

OSHA has no limit for carbofuran in the construction, maritime, or agriculture industries. The ACGIH has a TLV*-TWA of 0.1 mg/m³ for this substance. The PEL OSHA is proposing for carbofuran is 0.1 mg/m³ as an 8-hour TWA, and NIOSH concurs (Ex. 8-47, Table N1) that this limit is appropriate. This is the limit recently established for carbofuran in general industry.

Carbofuran, also called furadan, is a white, crystalline, odorless solid (HSDB 1990). Carbofuran is used as a miticide, a nematocide, and an insecticide on corn, alfalfa, tobacco, and other field groups. Carbofuran belongs to the methyl carbamate group of pesticides (HSDB 1990). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Carbofuran is a cholinesterase inhibitor in animals and humans. The oral LD50 in rats is 5.3 mg/kg, and the LC50 in the same species is 85 mg/m3 for an unspecified time (RTECS 1990). The dermal LDso in rabbits is 885 mg/kg (RTECS 1990). The N-methyl carbamate insecticides produce their effects by carbamylation of acetylcholinesterase enzyme, which allows the accumulation of acetylcholine at synapses in the nervous system. Rats fed carbofuran at a dietary level of 10 or 25 ppm for 180 days showed no significant histopathological effects at autopsy (Rotaur et al. 1981, Med. del Lavoro 72(5):399-403). Repeated intraperitoneal doses of 0.25 mg/kg carbofuran in mice caused a significant decrease in hemoglobin, number of erythrocytes and platelets, and hematocrits. Bone marrow depression and splenic hyperplasia were also seen (Gupta et al. 1981, in Toxicology 25(2-3):255-260). Rhesus monkeys did not display cholinesterase depression after exposure to concentrations equivalent to 0.56 mg/m3 of a 75-percent wettable carbofuran powder (Tobin 1970/Ex. 1-935). Inhibition of plasma, erythrocyte, and brain cholinesterase levels was evident

in rats at carbofuran levels of 50 ppm in the diet (Tobin 1970/Ex. 1-935). Six-hour exposures to concentrations of 0.86 mg/ m³ caused significant cholinesterase inhibition in experimental animals (Tobin 1970/Ex. 1-935).

In humans, overexposure to carbofuran causes the onset of the signs and symptoms of cholinesterase inhibition soon after exposure; however, recovery generally occurs rapidly after the cessation of exposure. Formulators and applicators of carbofuran who have been poisoned displayed the following signs and symptoms: blurred vision, nausea, weakness, and excessive perspiration (Hayes 1982, p. 454). If the exposure is severe, death caused by pulmonary edema and paralysis of the respiratory center may occur (Morgan 1989, in Recognition and Mgmt. of Pesticide Poisonings, p. 13).

Based on this evidence, OSHA is proposing a permissible exposure limit of 0.1 mg/m3 as an 8-hour TWA for this substance to protect employees in construction, maritime, and agriculture from the significant risk of cholinesterase inhibition potentially associated with exposure to this substance. The Agency preliminarily concludes that this limit is necessary to substantially reduce the significant occupational risk of material impairment of health posed by exposure to this substance. In addition, promulgation of this limit will make OSHA's PEL for carbofuran consistent across all regulated sectors.

CARBON DIOXIDE CAS: 124-38-9; Chemical Formula: CO₂ H.S. No. 1069

OSHA's current limit for carbon dioxide in construction and maritime is 5000 ppm as an 8-hour TWA. There is no PEL in agriculture. The ACGIH has a 5000-ppm TLV*-TWA for this substance with a 30,000-ppm TLV*-STEL, and NIOSH has a TWA REL of 10,000 ppm with a 10-minute 30,000-ppm ceiling limit; OSHA is proposing PELs of 10,000 ppm (8-hour TWA) and 30,000 ppm (15-minute STEL) for carbon dioxide in construction, maritime, and agriculture. These are the limits recently established in general industry.

Carbon dioxide is a colorless, odorless, noncombustible gas. This substance finds use as a refrigerant; in the production of urea, carbonates, methanol, hydrocarbons, and sodium salicylate; in the carbonation of beverages; as a propellant in aerosols; in livestock slaughtering; in food processing and preserving; in oil well stimulation; to inert flammable materials; in welding; in municipal water treatment; in cloud seeding; as a

pesticide and fertilizer; and in many other applications (HSDB 1990). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Exposure to high concentrations of carbon dioxide (CO2) causes metabolic effects (increases in respiratory rate; decreases in serum calcium and urinary phosphorus output (both indicators of mild metabolic stress) and central nervous system depression and excitation. In experimental animals, exposure to a 30,000-ppm concentration of CO2 caused elevated blood pressure and pulse, exposure to 50,000 ppm for 30 minutes caused signs of intoxication, and exposure to concentrations between 70,000 and 100,000 ppm causes unconsciousness within a few minutes (Hamilton 1974, Indus. Tox. 3rd ed., p. 237). The offspring of rats exposed to a mixture of CO2 (6%), oxygen (20%), and nitrogen (74%) on a single gestation day showed a significantly higher percentage of cardiac malformations than controls; administration of CO2 to pregnant rabbits on gestation days 7 to 12 caused 16 of 67 fetuses to have defects of the vertebral column (Shepard 1980, Cat. Teratogenic Agents 3rd ed., p.

Both the ACGIH (1986/Ex. 1-3) and NIOSH (1976 Criteria Document) cite studies indicating that continuous exposure to between 1.5 and 3 percent carbon dioxide (15,000 to 30,000 ppm) results in few, if any, adverse effects in exposed individuals. However, electrolyte imbalances and other metabolic changes have been associated with prolonged exposure to 10,000 to 20,000 ppm CO2 (Schulte 1964/Ex. 1-366; Gray 1950, as cited in ACGIH 1986/Ex. 1-3, p. 102). Increases in the rate of respiration have been observed among resting subjects exposed to carbon dioxide at a concentration of 39,500 ppm for periods shorter than a day and among exercising subjects exposed to airborne CO2 concentrations below 30,000 for the same period (Sinclair et al. 1969, as cited in ACGIH 1986/Ex. 1-3, p. 102). Many occupational fatalities have occurred as a result of workers entering CO2-contaminated wells and silos (Groves and Ellwood 1989, in Ann. Occup. Hyg. 33(4):519-535; Proctor, Hughes, and Fischman 1988, p. 119). The signs and symptoms of acute CO2 poisoning include psychomotor agitation, myoclonic twitching, eye flickering, dyspnea, dizziness, sweating, paresthesias, and restlessness (NIOSH 1976 Criteria Document; Williams 1958, Br. Med. J. 2:1012-1014; Smith, J.C. et al. 1985, in Gilman et al. Goodman and

Gilman's Pharm. Basis of Therapeutics 7th ed., p. 333–335).

Based on this evidence, OSHA is proposing a 10.000-ppm PEL as an 8-hour TWA and a 30,000-ppm STEL over 15 minutes to protect employees in the construction, maritime, and agriculture sectors from experiencing the metabolic and central nervous system changes that are associated with exposure to elevated short-term concentrations of CO₂. The Agency believes that these limits are necessary to substantially reduce these risks of material health impairment. Promulgation of these PELs also will make OSHA's limits for carbon dioxide consistent across all regulated sectors.

CARBON MONOXIDE CAS: 630–08–0; Chemical Formula: CO H.S. No. 1071

OSHA's limit for carbon monoxide in construction and maritime is 50 ppm as an 8-hour TWA. The limits in marine terminals and longshoring are a 50 ppm and, in confined spaces, a 100 ppm ceiling. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 50 ppm and a TLV*-STEL of 400 ppm for carbon monoxide. NIOSH (1973d/Ex. 1-237) recommends an 8-hour TWA limit of 35 ppm and a 200-ppm ceiling. For all sectors, OSHA is proposing PELs of 35 ppm (8-hour TWA) and 200 ppm (ceiling, measured over 5 minutes), respectively. OSHA is retaining the 100 ppm ceiling for CO in confined spaces in marine terminals and longshoring. NIOSH concurs (Ex. 8-47, Table N1) that the proposed limits are appropriate. These are the limits recently established for carbon monoxide in general industry.

Carbon monoxide is a flammable, colorless, practically odorless gas. This substance is used as a reducing agent in metallurgical operations, in the manufacture of metal carbonyls and zinc-based white pigments, and as a chemical intermediate. Most occupational exposures to this ubiquitous substance are the result of the incomplete combustion of organic material (HSDB 1990; Gosselin, Smith, and Hodge 1984, p. III-94).

Carbon monoxide has caused a large number of industrial fatalities as a result of its tendency to combine readily with hemoglobin to form carboxyhemoglobin (COHb). The Immediately Dangerous to Life and Health (IDLH) level for carbon monoxide is 1500 ppm (NIOSH 1987). At levels above this, workers quickly lose consciousness; if exposure is not terminated immediately, death by asphyxiation follows quickly.

In experimental animals, asphyxiation occurs when the airborne concentration

of CO exceeds 3 percent (30,000 ppm) (HSDB 1990). CO also causes reproductive and developmental effects in animals. The LC50 in rats is 1807 ppm for 4 hours (RTECS 1990). Rats were exposed (nose only) to 527, 1091, or 1800 ppm CO for 1 hour/day for 14 days; no treatment-related clinical effects were seen in animals of any dose group, although blood carboxy-hemoglobin levels increased in a dose-dependent manner. In controls, blood COHb levels averaged 2 percent and rose to 60 to 62 percent in the 1800-ppm group. Respiration rate and hemoglobin decreased in all groups in a dosedependent manner (Ayres, Mosberg, Burger, Hayes, Sagartz, and Coggins 1989, in Inhal. Toxicol. 1(4):349-363). Exposure of pregnant animals to concentrations of CO that are not maternally toxic causes destructive changes to the nervous systems of the fetuses; pregnant rats exposed to 150 ppm CO had fetuses that showed evidence of persistent central nervous system damage (Mactutus and Fletcher 1984, 1985, in Science 223:409-411 and Teratology 31:1-12). The offspring of mice and rabbits exposed during pregnancy also showed embryotoxic or developmental effects (RTECS 1990). Neonatal rats were exposed to 500 ppm CO for up to 32 days after birth; the CO exposure caused cardiomegaly, evidenced by a 47 percent increase in ventricular weight to body weight ratio in rats exposed for 28 days (Clubb, Penney, and Bishop 1989, in J. Mol. Cell. Cardiol. 21(9):945-955).

Excessive accumulations of COHb cause hypoxic stress in healthy individuals as a result of the reduced oxygen-carrying capacity of the blood. In patients with cardiovascular disease, such stress can further impair cardiovascular function. A number of studies show that 8-hour TWA exposures to 50 ppm carbon monoxide generally results in COHb levels of 8 to 10 percent. Such levels are not generally associated with overt signs or symptoms of health impairment in healthy individuals with strong cardiovascular systems who are working under nonstressful conditions. However, the ACGIH believes that a TLV*-TWA of 25 ppm, which results in COHb levels of 4 percent or less, may be necessary to protect workers with cardiovascular disease, because this condition places workers at higher risk of serious cardiovascular injury (ACGIH 1986/Ex. 1-3, p. 106). The NIOSH REL of 35 ppm TWA is also aimed at protecting workers with chronic heart disease (CHD); NIOSH believes that such workers should not be allowed to have

carboxyhemoglobin levels that approach
5 percent. In the prior rulemaking,
several commenters questioned the need
to lower the 8-hour TWA and to add a
STEL. In response to these commenters,
OSHA quoted the ACGIH (1986/Ex. 1–
3):

1093, 1953). During the Korean War,
autopsies performed on young soldi
with an average age of 22 years,
revealed that 77.3 percent had a gro
pathologic evidence of CHD. A stud
(Spiekerman, RE, JT Brandenberg, R
Anchor, and JE Edwards 1962. The

Each molecule of CO combining with hemoglobin reduces the oxygen carrying capacity of the blood and exerts a finite stress on man. Thus, it may be reasoned that there is no dose of CO that is not without an effect on the body. Whether that effect is physiologic or harmful depends upon the dose of CO and the state of health of the exposed individual. The body compensates for this hypoxic stress by increasing cardiac output and blood flow to specific organs, such as the brain or the heart. When this ability to compensate is overpowered or is limited by disease, tissue injury results [emphasis added].

Exposure to CO sufficient to produce COHb saturations in the 3-5% range impairs cardiovascular function in patients with cardiovascular disease and in normal subjects * * *. The primary effect of exposure to low concentrations of CO on workmen results from the hypoxic stress secondary to the reduction in the oxygencarrying capacity of blood * * *. Workmen with significant disease, both detected and undetected, may not be able to compensate adequately and are at risk of serious injury. For such workers, a TLV of 25 ppm * might be necessary. Even such a concentration might be detrimental to the health of some workers who might have far advanced cardiovascular disease * would appear to the Committee that the timeweighted TLV of 50 ppm for carbon monoxide might also be too high under conditions of heavy labor, high temperatures, or at high elevations (ACGIH 1986/Ex. 1-3, p. 106).

Thus, the ACGIH also regards a lower limit for CO as necessary to protect workers with cardiovascular or pulmonary disease or those working under stressful conditions.

OSHA believes that it is clearly necessary to set a CO level that protects workers who have CHD because (1) a large percentage of employees have it, (2) it is often not diagnosed or diagnosable, and (3) it is frequently fatal. The 35 ppm 8-hour TWA is designed to protect employees with asymptomatic CHD. The term CHD is generally used to refer to the process of atherosclerosis of the coronary arteries, which leads to disturbances in the myocardial blood supply.

Each year, more persons in the United States die from CHD than from any other disease. Coronary atherosclerotic heart disease is the most common form of cardiac disease in adults in the United States (Eros, WF, RH Holmes, and J Beyer. Coronary Disease Among United States Soldiers Killed in Action in Korea, J. Am. Med. Assoc. 152:1090—

autopsies performed on young soldiers, with an average age of 22 years, revealed that 77.3 percent had a gross pathologic evidence of CHD. A study (Spiekerman, RE, JT Brandenberg, RWP Anchor, and JE Edwards 1962. The Spectrum of Coronary Heart Disease in a Community of 30,000. A Clinicopathologic Study, Circulation 25:57-65) of autopsies in a stabilized population of 30,000 revealed that CHD was the cause of death in 40 percent of the males. In most cases, the first clinical manifestation of CHD is expressed either as the angina pectoris syndrome or as frank myocardial infarction. According to the Framingham, Massachusetts, study conducted by the U.S. Public Health Service, CHD is first manifested as myocardial infarction in one-sixth of all cases of CHD (NIOSH, Criteria for a Recommended Standard: Occupational Exposure to Carbon Monoxide, 1972).

It is clearly evident from these statements that the general worker population in the United States is composed of a very significant number of persons with CHD. Since the identification of such persons in the absence of overt clinical symptoms is virtually impossible, it is necessary to assume that the average worker has asymptomatic CHD, especially when his/her first clinical symptom may be sudden death (NIOSH, Criteria for a Recommended Standard: Occupational Exposure to Carbon Monoxide, 1972). Several studies demonstrate the significant risk associated with CO exposure, particularly with respect to coronary heart disease. A study of firefighters in Los Angeles (Barnard and Weber 1979) suggests that CO exposure during firefighting may be responsible for the high incidence of heart disease in firefighters. In some fires, peak exposures were occasionally as high as 3000 ppm CO, with 40 percent of peak values in the 100- to 500-ppm CO range. However, in some fires, the peak CO exposure was below 100 ppm. Although these peak exposures in firefighters were high, firefighters are likely to be exposed overall for fewer hours than the workers of concern in this rulemaking.

A prevalence study was recently performed on angina pectoris, ECG changes, and blood pressure that involved 1,000 workers from 20 foundries (Hernberg, Karava, Koskela, and Luoma. 1976. Angina pectoris, ECG findings and blood pressure of foundry workers in relation to carbon monoxide exposure. Scand. J. Work Environ. & Health 2). On the basis of actual measurements of air concentrations of

CO, the workers were divided into three exposure groups. The workers' smoking habits, both present and past, were factored into the analysis. No association between CO exposure and blood pressure or ECG changes was found. However, a clear dose-response was found with regard to the prevalence of angina (as obtained by history on a World Health Organization-recommended questionnaire) and CO exposure in workers (both smokers and nonsmokers).

In order to obtain some quantitative estimate of the process of selection for healthy workers in the foundries studied, the authors contacted workers who had left this type of work. Fourteen percent of those who had left foundry work after less than 1 year of employment and 7 percent of those who had left it after more than 5 years of foundry employment reported health impairment or disability as the reason for quitting foundry work. The authors conclude that this evidence indicates that less healthy workers left employment early on. This selection process, which is apparent in this study and also in the American foundry study by Redmond, results in an overrepresentation of fit and healthy workers in physically heavy work, such as foundry work.

NIOSH conducted a prospective cohort mortality study among 1,558 white male motor vehicle examiners who were employed in New Jersey for a minimum of 6 months between 1944 and 1973 (Stern, Lemen, and Curtis 1981). Industrial hygiene surveys indicated that the examiners were exposed to carbon monoxide at a time-weightedaverage (TWA) of 10 to 24 ppm. Using a modified life table technique, the expected deaths were compared to the expected deaths through August 1973. The overall deficit of mortality observed (SMR 80) in this occupational cohort during the first 10-year period was to be expected as a result of the widely accepted "healthy worker effect." However, the component SMR for cardiovascular disease deaths (134) was unexpected, since the "healthy worker effect" had been most significantly associated with decreased cardiovascular disease mortality (McMichael 1976, in Standardized Mortality Ratios and the "Healthy Worker Effect": Scratching Beneath the Surface, J. Occup. Med. 18:165-168). The authors refer to the excess of cardiovascular disease mortality found within the first 10 years following employment as "non-statistically significant, but highly unusual." OSHA believes that this evidence suggests that

slightly elevated COHb may contribute to excess cardiovascular disease rates in a healthy population that is of average fitness (since the work is not physically hard).

A recent study (Kristensen 1989, in Scand. J. Work Environ. Hlth. 15(4): 245-264) reviewed the epidemiological evidence for an association between carbon monoxide and heart disease and concluded that carbon monoxide exerts acute and possibly reversible short-term effects that can increase the risk of cardiovascular disease. Twenty-four male volunteers with stable angina pectoris exercised after breathing air or low levels (not further specified) of CO; subjects' blood COHb levels increased to 3 percent after CO exposure, and oxygen uptake was also significantly reduced (Kleinman, Davidson, Vandagroff, Caiozzo, and Whittenberg 1989, in Arch. Environ. Hlth. 44(6): 361-

In another recent study, male volunteers aged 35 to 75 with stable exertional angina pectoris and positive exercise treadmill tests were exposed to CO concentrations designed to cause 2.2 to 4.4 percent COHb levels after exercise. The subjects performed a symptom-limited exercise test on a treadmill, followed by exposure for 1 hour to CO, and then performed a second treadmill test. All subjects who completed the study (N=63) showed significant decreases in time to onset of ischemic ST-segment changes; in the 2 percent COHb group, this change equalled 5.1 percent, and in the 4 percent COHb group it averaged a 12.1 percent decrease (Allred, Bleecher, Chaitman, Dahms, Gottlieb, Hackney et al. 1989, in Res. Rep. Hlth. Effect. Inst.

In addition, a number of recent studies point to CO's reproductive and neurotoxic/behavioral effects. For example, episodes of acute CO poisoning have been known to lead to late-onset fatal demyelination in the exposed worker (Winter and Miller 1976, in JAMA 236: 1502-1504), mental damage manifested as gross neuropsychiatric change, or personality deterioration (Smith and Brandon 1973, in Br. Med. J. 1: 318-321). Carbon monoxide is also known to cross the placental barrier in humans (Gosselin, Smith, and Hodge 1984, p. III-97). The infants of mothers who were acutely poisoned by CO during pregnancy often show evidence of neurological damage and may have gross brain damage (Goodman 1980, Pharm. Basis Therap. 6th ed., p. 1643).

Another study, Mortality of Steelworkers Employed in Hot Jobs (Redmond 1977) is a well-designed investigation of the possible relationships between heat stress (both environmental and metabolic heat load) and cause-specific mortality patterns in a cohort of 69,414 steelworkers. Two main sets of data were analyzed: (1) Field data, and (2) mortality data. The field data were divided into four computer files: (1) indoor environmental measurements, (2) outside plant environmental measurements, (3) National Weather Service Data, and (4) activity data. From these data, estimations of heat exposure and work loads were made. Workers were then divided into four categories based on heat and energy expenditures, and the mortality experience of workers in each category was compared to mortality in the control group. The investigators made no attempt to characterize exposures to carbon monoxide.

For mortality from cardiovascularrenal disease (CVR), relative risks were significantly low for those workers in the two higher environmental heat categories, indicating a possible relationship between decreased mortality and environmental heat stress. When the mortality experience was examined by length of exposure, a higher than expected risk was noted among workers with less than 6 months of exposure in all exposure groups. This was less than the expected risk of mortality due to cardiovascular-renal disease once the initial 6 month employment period has been exceeded. The authors state that "(t)hese higher risks may be indicative of a relationship between inability to work in jobs involving heat stress and health. This selection for health may at least partially explain the results for mortality from cardiovascular disease. Workers who are less fit leave the job after varying lengths of exposure, thus resulting in a downward trend in mortality for workers who remain on the

When mortality from arteriosclerotic heart disease was separated out from the CVR heading, the risks of dying were significantly low for workers in the two highest exposure categories. When the mortality patterns were examined by length of exposure, higher risks were noted among those with short exposure times. These trends are consistent with those seen for cardiovascular mortality.

The American Iron and Steel Institute (AISI) pointed out in the general industry hearing (Ex. 129) that the high heat stress workers would also have had higher exposure to CO. AISI argued that it was therefore not necessary to lower the exposure limit for CO. OSHA

believes that the more likely explanation of this result, as seen in several of the other studies discussed, is the healthy worker effect. Only persons with substantially above-average cardiovascular fitness can perform these physically demanding jobs. Persons with average or below-average cardiovascular fitness either do not take such jobs in the first place or leave them after a few months. Furthermore, the level of exertion the jobs require keeps cardiovascular fitness high. Consequently, the low CHD rates seen are caused by the high proportion of cardiovascularly fit workers in these jobs. The study cannot therefore be said to contradict the need to reduce COHb levels to prevent excess CHD risk in workers with average or below-average levels of cardiovascular fitness. In addition, the study did not attempt to correlate CO levels and cardiovascular disease, and no CO measurements were

As pointed out above, cardiovascular disease (detected or undetected) and pulmonary impairment are widespread in the general population in this country, in workers as well as other subpopulations. In addition, OSHA is particularly concerned about the adverse effects of CO because workers regularly encounter complex and stressful situations at work, including heat stress, jobs demanding heavy exertion, and tasks requiring both judgment and motor coordination. OSHA standards are intended to protect workers of average and below-average fitness and those who engage only intermittently in heavy physical labor and who do not therefore receive the benefit of physical conditioning.

OSHA thus preliminarily finds that, in construction, maritime, and agriculture, the proposed 8-hour TWA of 35 ppm for carbon monoxide is needed to reduce the significantly increased risk of cardiovascular disease that is associated with overexposure to CO. The Agency believes that a ceiling of 200 ppm is necessary to ensure that peak CO exposures are kept below the 1500 ppm IDLH level by a reasonable safety factor. The ceiling limit will also assist in keeping COHb levels below 5 percent; the ceiling will be measured over 5 minutes to permit the use of simpler monitoring techniques.

Based on this evidence, OSHA is proposing an 8-hour TWA of 35 ppm and a ceiling of 200 ppm as the PELs for carbon monoxide in the construction, maritime, and agriculture industries. In the construction and marine terminal industries, employees regularly enter and work in confined spaces. In these

sectors, CO therefore presents an especially great danger of death from IDLH levels of CO. Consequently, OSHA is retaining the 100 ppm ceiling for CO in confined spaces in these sectors, as well as the provision requiring monitoring of these spaces.

The Agency preliminarily concludes that these limits will ensure that the COHb levels of exposed workers (especially of non-smokers) in these sectors are maintained at or below 5 percent, which will protect those workers at greater risk because of cardiovascular or pulmonary impairment. In addition, these revised limits will protect healthy workers in the affected sectors who must work in environments involving intermittent exertion, heat stress, or other strenuous conditions. OSHA believes that these limits are necessary to substantially reduce the significant occupational risk associated with both chronic and peak exposures to carbon monoxide in the workplace. OSHA preliminarily finds that the hypoxic stress associated with overexposures to carbon monoxide clearly constitutes a material impairment of health and functional capacity. In addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

CHLORPYRIFOS CAS: 2921-88-2; Chemical Formula:

C₉H₁₁Cl₂NO₃PS H.S. 1091

OSHA has no limit for chlorpyrifos in the construction, maritime, or agriculture sectors. The ACGIH has a TLV*-TWA of 0.2 mg/m³ and a TLV*-STEL of 0.6 mg/m³, with a skin notation, for chlorpyrifos. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the PEL being proposed. OSHA is proposing a 0.2-mg/m³ 8-hour TWA and a skin notation for chlorpyrifos; this is the limit recently established in general industry.

Chlorpyrifos is a white, crystalline solid with a mild, mercaptan-like odor (EPA Fact Sheet 1985). Chlorpyrifos is an organophosphate pesticide that is used on grain crops (EPA Fact Sheet 1985). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Exposure to chlorpyrifos causes cholinesterase inhibition in humans and animals. The oral LD₅₀ in rats is 82 mg/kg, and the dermal LD₅₀ in rabbits is 2000mg/kg (RTECS 1990). Chlorpyrifos is an active inhibitor of plasma cholinesterase but has only moderate capacity to reduce red blood cell cholinesterase or to cause cholinergic

symptoms and systemic injury (ACCIH 1986/Ex. 1-3, p. 138). Particle inhalation has been shown to cause mild plasma cholinesterase depression in dogs exposed for 4 hours at the upper end of a 140- to 280-mg/m3 range (Spencer 1968, as cited in ACGIH 1986/Ex. 1-3, p. 138). A recent study (Corley, Calhoun, Dittenber, Lomax, and Landry 1989, in Fund. Appl. Toxicol. 13(3):616-618) examined the subchronic inhalation toxicity of chlorpyrifos in rats. Rats were exposed (nose-only) to 5.2, 10.3, or 20.6 ppb chlorpyrifos vapor for 6 hours/ day, 5 days/weeks, for 13 weeks. No significant treatment-related histopathological, hematological, serum chemistry, or cholinesterase activity changes were seen in these animals, leading the authors to conclude that chlorpyrifos has low subchronic inhalation toxicity in rats. Cats were given a single sublethal oral'dose of chlorpyrifos; doses ranged from 10 mg/ kg to 40 mg/kg. No signs of poisoning were seen at the lowest dose, but the high-dose group developed clinical signs of toxicity (Hooser, Beasley, Sundberg, Harlin 1988, in Am. J. Vet. Res. 49(8):1371-1375). Dogs and rats fed 3.0 mg/kg chlorpyrifos daily for 2 years showed no adverse effects (FAO/WHO (Food and Agriculture Organization/ World Health Organization) 1972, as cited in ACGIH 1986/Ex. 1-3, p. 138). Male and female rats showed no teratogenic or reproductive effects when fed 1.0 mg/kg per day (Dow Chemical Company 1972a, as cited in ACGIH 1986/Ex. 1-3, p. 138).

Workers applying chlorpyrifos as a spray were exposed to 0.5 percent chlorpyrifos emulsion and exhibited a marked decrease in plasma and red cell cholinesterase levels (Eliason, Cranmer, von Windeguth et al. 1969/Ex. 1-633). In five of seven exposed sprayers, this reduction was greater than 50 percent. However, another study showed no ill effects on cholinesterase metabolism when human volunteers were exposed to an ultra-low-volume spray (0.8 um/m3 for 3 to 8 minutes) (Ludwig, Kilian, Dishburger, and Edwards 1970/Ex. 1-563). Human cholinesterase levels appear to be less affected by dermal exposure than do those of rabbits (ACGIH 1986/Ex. 1-3, p. 138). However, when chlorpyrifos was administered in four repeated dermal doses of 25 mg/kg. each applied for 12 hours, human volunteers did exhibit depressed plasma cholinesterase levels. Human volunteers ingesting 0.03mg/kg chlorpyrifos for 3 weeks showed no cholinesterase effects, but subjects ingesting 0.1 mg/kg demonstrated plasma cholinesterase depression (Dow Chemical Company

1973f, as cited in ACGIH 1986/Ex. 1-3, p. dermal LD₅o in rabbits is 2000 mg/kg 138). A recent Dow study (Brenner, Bond, McLaren, Greene, and Cook 1989, Br. J. Ind. Med. 46(2):133-137) showed that the prevalence of illness and of symptoms was not elevated over that of controls in a group of 175 workers exposed between 1977 and 1985 to chlorpyrifos during its manufacture or formulation.

Based on this evidence in humans and animals, OSHA is proposing a PEL of 0.2 mg/m3 as an 8-hour TWA, and a skin notation, for chlorpyrifos in the construction, maritime, and agriculture sectors. The Agency believes that these limits for chlorpyrifos will protect workers in these industries from the significant risk of cholinesterase inhibition caused by exposure to this substance. OSHA believes that the skin notation is necessary to prevent the systemic effects that have been demonstrated to occur in humans dermally exposed to chlorpyrifos. OSHA preliminary finds that the cholinesterase inhibition and systemic effects associated with exposure to chlorpyrifos constitute material impairments of health and that the proposed PEL is necessary to substantially reduce these risks. In addition, promulgation of the proposed limit will make OSHA's PEL for chlorpyrifos consistent across all regulated sectors.

CRUFOMATE

CAS: 299-86-5: Chemical Formula: C12H19CINO3P H.S. No. 1103

OSHA has no limit for crufomate in the construction, maritime, or agriculture industries. The ACGIH has a TLV*-TWA of 5 mg/m3 and a TLV*-STEL of 20 mg/m³ for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 5 mg/ m3 for crufomate in the construction. maritime, and agriculture industries. This is the limit recently established in general industry.

Pure crufomate exists as a colorless crystalline solid, and commercial crufomate, also called Ruelene, is a yellow oil. Crufomate is an antihelmintic that is used on cattle, sheep, and goats to control grubs, lice, and horn flies (Clayton and Clayton 1981, p. 4833). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA)

Crufomate actively inhibits both plasma and erythrocyte cholinesterase. The oral LD50 in rats is 460 mg/kg, the lowest lethal concentration in the same species is 12 mg/m3 for 4 hours, and the

(RTECS 1990). Applied to the eyes of rabbits, crufomate (undiluted or as a 10 percent solution) caused corneal cloudiness, conjunctival irritation, and signs that the animals were experiencing pain (Clayton and Clayton 1981, p. 4834). In contact with the intact or abraded skin of rabbits, this substance caused slight redness (Clayton and Clayton 1981, p. 4834).

A study showed that ingestion of 200 mg of crufomate daily for seven days caused no apparent cholinesterase inhibition in the human subjects of this controlled study; however, rats and dogs receiving higher doses (5 mg/kg/day) for 2 years did show this effect (McCollister, Olson, Rowe et al. 1968/ Ex. 1-350). Rats fed 1000 ppm crufomate for 2 years showed marked cholinesterase inhibition, growth retardation, testicular degeneration, atrophy of the hind quarters, and slight degeneration of the sciatic nerve (McCollister, Olson, Rowe et al. 1968/ Ex. 1-350).

Because cholinesterase inhibition is a very sensitive indicator of exposure, OSHA preliminarily concludes that the proposed 8-hour TWA limit of 5 mg/m3 is needed to provide an appropriate margin of safety below the ingestion NOEL of 200 mg/day for humans, which corresponds approximately to an 8-hour inhalation exposure of 20 mg/m3. The Agency believes that this PEL is necessary to protect workers in construction, maritime, and agriculture from a significant risk of material health impairment in the form of cholinesterase inhibition. In addition, promulgation of the proposed PEL will make OSHA's limit for crufomate consistent across all regulated sectors.

CYANAMIDE

CAS: 420-04-2; Chemical Formula: H2NC=N

H.S. No. 1104

OSHA has no limit for cyanamide in the construction, maritime, and agriculture industries. The ACGIH has a TLV*-TWA of 2 mg/m3 for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N1) that the proposed limit is appropriate. OSHA is proposing an 8-hour PEL of 2 mg/m3 for cyanamide in construction, maritime, and agriculture; this is the limit recently established in general industry.

Cyanamide, which is also called hydrogen cyanamide, is a deliquescent, crystalline solid; no information is available on its odor. Cyanamide is used as a chemical intermediate and as a crease- and fire-proofing agent in textiles.

Cyanamide is a severe irritant and caustic of the eyes, mucous membranes, and respiratory tract. In addition, this substance produces Antabuse-like effects when exposed individuals also ingest alcohol. The oral LD50 in rats is 125 mg/kg, and the dermal LD50 in rabbits is 590 mg/kg (RTECS 1990). In contact with the eye, cyanamide causes severe irritation; this substance is a caustic that destroys any tissue it comes into contact with, especially when moisture is present (Grant 1986, p. 286). Cyanamide dust is irritating to the respiratory tract (Grant 1986, p. 286). Acutely poisoned rats exhibited signs of parasympathetic overactivity, including miosis, excessive salivation, lacrimation, and twitching (Grant 1986, p. 286).

When cyanamide is ingested or inhaled by a person who has also consumed an alcoholic beverage, the person experiences vasodilation of the face and neck, tachycardia, tachypnea, nausea, vomiting, and hypotension. This syndrome is referred to as the Antabuse syndrome. Studies of cyanamide's Antabuse-like effects indicate that the effect is about one-half that of an equivalent dose of tetraethylthiuram disulfide (Antabuse) and one-sixth that of tetramethyl thiuram disulfide (Hald, Jacobsen, and Larsen 1952/Ex. 1-905). Workers whose skin is in contact with cyanamide can develop a severe and persistent dermatitis (Gerrin 1989).

Based on this evidence in humans and animals, OSHA is proposing an 8-hour TWA limit of 2 mg/m3 TWA for cyanamide. The Agency preliminarily concludes that this limit will protect workers in construction, maritime, and agriculture from the significant risks of sensory irritation and of the Antabuse syndrome in workers who have ingested alcohol. The Agency believes that this limit will substantially reduce these significant risks, which constitute material health impairments. In addition, promulgation of the proposed PEL will make OSHA's limit for cyanamide consistent across all regulated sectors.

DICHLORVOS (DDVP) CAS: 62-73-7; Chemical Formula: (CH3O)2POOCH=CCl2 H.S. No. 2051

OSHA's permissible exposure limit for dichlorvos in general industry, construction, and maritime is an 8-hour TWA of 1 mg/m3; this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. There is no limit in agriculture. The ACGIH has a limit of 0.1 ppm (≈1 mg/

m³) as an 8 hour TLV*-TWA, with a skin notation, for dichlorvos. NIOSH has no REL but concurs (Ex. 48-7, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 1 mg/m³, and a skin notation, for dichlorvos in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Dichlorvos is a colorless to amber liquid that has a mild chemical odor. It is used as an insecticide and fumigant and is a primary ingredient in pest strips (Proctor, Hughes, and Fischman 1988, p. 194; Hayes 1982, p. 343). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Dichlorvos causes cholinesterase inhibition in humans and animals, as well as reproductive effects in animals. In rats, the oral LDse is 25 mg/m3 and the LCoo is 15 mg/m3 for 4 hours (RTECS 1990). The dermal LDse in rabbits is 107 mg/kg (RTECS 1987). No illness occurred in monkeys exposed to dichlorvos concentrations greater than 7 mg/m3 for 2 hours/day for 4 days; however, miosis and a rapid drop in blood cholinesterase were observed in these animals (Witter et al. 1961, in Hayes 1982, p. 344). Monkeys exposed continuously for 1 week to dichlorvos concentrations between 1.4 to 2.0 mg/m3 developed severe cholinesterase inhibition (Durham et al. 1959). Continuous exposure of monkeys and rats to a dichlorvos concentration of 0.27 mg/m3 for 4 days had no effect on cholinesterase levels (Durham et al. 1959, in Hayes 1982, p. 344). Dichlorvos given to pregnant rats by intraperitoneal injection at a dose of 15 mg/m3 on the 11th day of pregnancy caused malformations in three of 41 fetuses (Kimbrough and Gaines 1968, in IARC 1979, Vol. 20, p. 108). Mice exposed to a single oral dose of 40 mg/kg showed extensive injury to the seminal epithelium; similar but less extensive changes were seen in the reproductive tissue of animals given doses of 10 mg/ kg/day for 18 days (Krause and Homola 1972, in Hayes 1982, p. 347). Several carcinogenicity bioassays have failed to show a statistically significant increase in the incidence of tumors, and the International Agency for Research on Cancer has concluded that the data in animals are inadequate to evaluate the carcinogenicity of this substance (IARC 1979, Vol. 20, pp. 97-123).

Human exposure to dichlorvos can occur by inhalation, ingestion, or skin absorption, and the signs and symptoms

associated with exposure include chest tightness, bronchial secretion, laryngeal spasms, cyanosis, blurred vision, rhinorrhea, headache, anorexia, nausea, abdominal cramps, and diarrhea (Proctor, Hughes, and Fischman 1988, p. 194). Signs and symptoms usually onset soon after exposure but may be delayed for as long as 12 hours (Proctor, Hughes, and Fischman 1988, p. 194). Effects on the central nervous system include giddiness, confusion, ataxia, slurred speech, Cheyne-Stokes respiration, convulsions, coma, and loss of reflexes (Proctor, Hughes, and Fischman 1988, p. 194). Complete recovery from exposurerelated symptoms usually occurs within 1 week (Proctor, Hughes, and Fischman 1988, p. 194). Dichlorvos also causes a persistent contact dermatitis of allergic origin (Mathias 1983; Matsushita et al. 1985, in Proctor, Hughes, and Fischman 1988, p. 195). Of 28 volunteers exposed to a concentration of 1 mg/m3 dichlorvos for 7.5 to 8.5 hours (single exposures), 20 to 25 percent experienced plasma cholinesterase depression (ACGIH 1986, p. 192). Studies on pesticide workers handling dichlorvos have shown significant reductions in blood cholinesterase and in the number of lymphocytes and monocytes, as well as leukocytosis and neutrophilia; levels returned to normal within 2 weeks after the cessation of exposure (Pukach et al. 1974, in ACGIH 1986, p. 192). Symptoms of dichlorvos intoxication seen in these workers included weakness, headache, nausea, abdominal cramps, blurred vision, non-reactive pupils, chest tightness, salivation, sweating, convulsions, and coma (Pukach et al. 1974). In a study in which 13 workers were exposed to an average concentration of 0.7 mg/m3 dichlorvos for 12 months, erythrocyte cholinesterase activity was reduced by 35 percent and serum cholinesterase activity showed a 60 percent reduction (Menz, Luetkemeir, and Sachsse 1971, in Proctor, Hughes, and Fischman 1988, p.

Based on this evidence in humans and animals, OSHA preliminarily concludes that dichlorvos causes cholinesterase inhibition. OSHA believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. OSHA believes that the proposed PEL of 1 mg/m³ as an 8-hour TWA, and a skin notation, are necessary to substantially reduce the risk of this material health impairment. In addition, establishing this limit for dichlorvos in agriculture will make OSHA's PEL for this substance

consistent across all OSHA-regulater sectors.

DICROTOPHOS

CAS: 141-66-2; Chemical Formula:

C₆H₁₆NO₅P

H.S. No. 1131

OSHA has no limit for dicrotophos in the construction, maritime, or agriculture industries; the ACGIH has a TLV*—TWA of 0.25 mg/m³, with a skin notation, for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N1) that the proposed limit is appropriate. OSHA is proposing an 8-hour TWA of 0.25 mg/m³, and a skin notation, for dicrotophos in construction, maritime, and agriculture. This is the limit recently established for dicrotophos in general industry.

Dicrotophos is a yellow-brown liquid with a mild, ester-like odor (Sittig 1985, p. 335). This substance is an organophosphate insecticide that is used on apples, cotton, and other crops (HSDB 1990). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Dicrotophos is a cholinesterase inhibitor in humans and animals. The oral LDso in rats is 13 mg/kg, and the LC50 in the same species is 90 mg/m3 for 4 hours (RTECS 1990). The dermal LDso in rabbits is 168 mg/kg (RTECS 1990). Male rats exposed by inhalation to dicrotophos at a concentration of 910 mg/m3 for 1 hour rapidly became ill but recovered quickly after exposure was discontinued (ACGIH 1986, p. 193). Twoyear feeding studies in rats given 0, 1, 10, or 100 ppm dicrotophos showed no detectable effects at the 1-ppm concentration. At the higher concentrations, decreased body weights (as compared with those of controls) and cholinesterase inhibition were observed (Woodard Research Corporation 1967, as cited in ACGIH 1986/Ex. 1-3, p. 193). Dietary studies in dogs showed both plasma and erythrocyte cholinesterase inhibition after exposure to a 16-ppm concentration of dicrotophos, but no significant ill effects were seen at concentrations of 0, 0.16, or 1.6 ppm (Woodard Research Corporation 196', as cited in ACGIH 1988/Ex. 1-3, p. 193).

At least two cases of accidental poisoning by dicrotophos have been reported. The first case involved a tractor driver who had been applying dicrotophos to crops and who had additionally sprayed the inside of his house with this substance. He developed abdominal cramps, nausea, vomiting, diarrhea, increased sweating, salivation,

dyspnea, tremor, generalized weakness, and reduced plasma and blood cholinesterase activities (Hayes 1982, p. 362). After appearing to recover over a 5-day period, this patient suffered respiratory arrest and required respiratory ventilation for several days. He subsequently recovered completely (Hayes 1982, p. 362). In the other case, a man accidentally ingested dicrotophos and lost consciousness. On admission to the hospital, he was without respiration or pulse. Aggressive treatment with atropine and pralidoxime, and assisted ventilation, led to his subsequent recovery (Hayes 1982, p. 362)

Based on this evidence, OSHA is proposing an 8-hour TWA permissible exposure limit of 0.25 mg/m3, with a skin notation, for dicrotophos in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit is necessary to protect workers in these sectors from the material impairments of health, such as cholinesterase inhibition, potentially associated with inhalation, ingestion, or dermal exposure to this substance in the workplace. OSHA believes that this limit will substantially reduce this significant risk; in addition, promulgation of this limit will make the PEL for dicrotophos consistent across all regulated sectors.

DIMETHYLANILINE (N-Dimethylaniline) CAS: 121-69-7; Chemical Formula: C6H5N(CH3)2 H.S. No. 1143

OSHA's permissible exposure limit for dimethylaniline in construction and maritime is 5 ppm as an 8-hour TWA, with a skin notation. There is no limit in agriculture. The ACGIH has an 8-hour TLV%-TWA of 5 ppm and a 15-minute TLV®-STEL of 10 ppm, with a skin notation, for dimethylaniline. OSHA is proposing to retain its 8-hour TWA PEL of 5 ppm, and the skin notation, and to add a STEL of 10 ppm for this substance in construction and maritime. OSHA is also proposing to apply these limits in agriculture. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limits being proposed, which are identical to those recently established for dimethylaniline in general industry.

Dimethylaniline is a yellow to brown, oily liquid. This substance finds use as an analytical reagent and a dye precursor (HSDB 1990).

Dimethylaniline induces tissue hypoxia by causing the formation of methemoglobin in the blood. This substance is also a mild irritant of the eyes and skin (RTECS 1990). The oral LDso in rats is 1410 mg/kg, and the lowest lethal concentration in the same

species is 250 mg/m3 for 4 hours (RTECS H.S. No. 1146 1990). Instilled into the eyes of rabbits, dimethylaniline caused a moderate degree of injury (graded 5 on an ascending severity scale of 1 to 10) (Grant 1974, p. 401). Hamblin (1963a/Ex. 1-1084) reported that dimethylaniline is quantitatively less toxic than aniline. Dogs administered a single oral dose of 50 mg/kg exhibited methemoglobinemia, and absorption of dimethylaniline through the skin can increase the overall exposure (Hamblin 1963b/Ex. 1-1085). Rats survived an 8-hour exposure to the concentrated vapor (Smyth, HF et al. 1941, in Proctor, Hughes, and Fischman 1988, p. 210). Rats continuously exposed to dimethylaniline for 100 days at a concentration of 0.3 mg/m3 showed significant changes in the central nervous system, liver, and blood (Markosyan 1969, in Gigiena Sanit

The literature on industrial experience with dimethylaniline is limited. Hamilton (1919/Ex. 1-741) reported collapse, prolonged unconsciousness, visual disturbances, and intense abdominal pain following the severe overexposure of two workers. The signs and symptoms of acute overexposure include headache, cyanosis of the lips, nose, and earlobes, and anemia (Proctor, Hughes, and Fischman 1988, p. 209). Exposure to dimethylaniline depresses the central nervous system and both cardiac and smooth muscle function; increased pulse and respiration may be followed by convulsions and death due to respiratory arrest (HSDB 1990).

Based on this evidence, the Agency is proposing to retain the 8-hour TWA PEL of 5 ppm and a skin notation for dimethylaniline in construction and maritime and to add a STEL of 10 ppm to this limit; OSHA is also proposing to apply the TWA and STEL and the skin notation in agriculture. OSHA believes that the STEL is necessary to afford protection from the central nervous system depression that follows acute exposures. OSHA preliminarily concludes that these limits, taken together, will provide workers in construction, maritime, and agriculture with protection from the significant risks of skin absorption, methemoglobinemia, and neuropathic effects associated with exposure to this substance; the Agency believes that these effects clearly constitute material health impairments. In addition, promulgation of the proposed limits will make OSHA's PELs for dimethylaniline consistent across all regulated sectors.

DIOXATHION (DELNAV) CAS: 78-34-2; Chemical Formula: C12H26O6P2S4

OSHA has no permissible exposure limit for dioxathion in the construction, maritime, or agriculture industries. The ACCIH has a TLV*-TWA of 0.2 mg/m3, with a skin notation. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed in construction, maritime, and agriculture, which is 0.2 mg/m3 as an 8-hour TWA, with a skin notation. This is the limit recently established for dioxathion in general industry.

Dioxathion, also called Delnav, is an organophosphate pesticide that is used against external livestock pests, including ticks and citrus mites (Hayes 1982, p. 401). This substance is a nonvolatile, very stable, dark amber liquid. When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Dioxathion is a cholinesterase inhibitor in humans and animals. The commercial product contains both the cis- and trans-isomers of 2,3-pdioxanedithiol; the cis-isomer is approximately four times as acutely toxic as the trans-isomer (ACGIH 1986/ Ex. 1-3, p. 219). The oral LD50 in rats is 20 mg/kg, and the LCso in the same species is 1398 mg/m3 for 1 hour (RTECS 1990). The dermal LDso in rabbits is 85 mg/kg (RTECS 1990). Acutely poisoned animals show decreases in cholinesterase activity as well as dyspnea, nausea, vomiting, diarrhea, tremor, and ataxia (Hayes 1982, p. 401). Instillation of 0.1 ml dioxathion into the rabbit eye produces mild, transient conjunctivitis but no corneal damage (ACGIH 1986/Ex. 1-3, p. 219). Rats fed 10 mg/kg dioxathion for 14 days and dogs given 10 doses of 0.8 mg/ kg dioxathion over a 14-day period showed cholinesterase inhibition (HSDB 1990). Rats fed dioxathion (100 ppm of the diet) for 90 days displayed tremor and excitability (Gosselin, Smith, and Hodge 1984, p. II-299). When dioxathion was administered to three successive generations of albino rats at a dietary level of from 3 to 10 ppm, no abnormalities were observed in rats of any generation (Kennedy, Frawley, and Calandra 1973/Ex. 1-340). A 2-year carcinogenicity bioassay involving rats and mice fed dioxathion had negative results (National Cancer Institute 1978, Technical Report Series 125:43).

Human volunteers who ingested 0.075 mg/kg/day of dioxathion for as long as 60 days had no symptoms related to plasma or blood cholinesterase activity. while those ingesting 0.15 mg/kg/day exhibited a slight decrease in plasma

cholinesterase activity (Frawley, Weir, Tusing et al. 1963/Ex. 1–317). The World Health Organization has estimated an acceptable daily intake for humans of 0.0015 mg dioxathion/kg (WHO 1967, as cited in ACGIH 1986/Ex. 1–3, p. 219).

Based on this evidence in humans and animals, OSHA is proposing an 8-hour TWA PEL of 0.2 mg/m3 for dioxathion in construction, maritime, and agriculture. The Agency is also proposing a skin notation for this substance. OSHA preliminarily concludes that these limits are necessary to protect workers in these sectors from the significant risk of metabolic effects associated with inhalation and oral exposure and with dermal penetration of this substance. The Agency believes that these limits will substantially reduce these significant risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for dioxathion consistent across all regulated sectors.

DISULFIRAM
CAS: 97-77-8; Chemical Formula:
C₁₀H₂₀N₂S₄
H.S. No. 1151

OSHA has no limit for disulfiram in construction, maritime, or agriculture. The ACGIH has a TLV®-TWA of 2 mg/m³ for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 2 mg/m³ for disulfiram in the construction, maritime, and agriculture sectors. This is the limit recently established for this substance in general industry.

Disulfiram is a white, crystalline powder that has a slight odor (HSDB 1990). This substance is used as a rubber accelerator and vulcanizer, a seed disinfectant, a fungicide, and as an alcohol deterrent in alcohol aversion therapy (HSDB 1990). When used to treat alcoholics, disulfiram is marketed under many trade names, including Antabuse and Antalcol (RTECS 1990). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Disulfiram causes vasodilation of the vessels of the face and neck, increased heart and respiratory rates, decreased blood pressure, and nausea and vomiting. The LD₅₀ in rats is 500 mg/kg (RTECS 1990). This compound is highly toxic when injected intraperitoneally, with an LD₅₀ of 75 mg/kg for mice (RTECS 1990). Acutely poisoned animals show ataxia, hypothermia, and flaccid paralysis (IARC 1976, Vol. 12, p. 89). The effects of high-dose ingestion include degenerative changes in the liver and

kidneys; very high doses of disulfiram can cause leukopenia and marked hypoplasia or aplasia of the bone marrow (Brieger 1947/Ex. 1-717). In the most seriously afflicted animals, the blood urea nitrogen sometimes increased and the thymol turbidity test was positive (Brieger 1947/Ex. 1-717). Rats given chronic doses of disulfiram (1000 to 2000 mg/kg) in the diet had reduced growth rates, decreased longevity, and reduced reproductive capabilities (Holck et al. 1970, in IARC 1976, Vol. 12, p. 89). Oral, parenteral, or subcutaneous administration of disulfiram to rats or mice during pregnancy leads to embryotoxic and/or developmental effects in the offspring (RTECS 1990; Shepard 1980, Catalog of Teratogenic Agents, 3rd ed., p. 395).

Adverse health effects occur in humans who consume alcohol and are simultaneously exposed to disulfiram. For individuals who drink alcohol and are exposed to disulfiram, the symptoms of exposure are facial vasodilation, tachycardia, tachypnea, nausea, vomiting, pallor, and hypotension. High doses of disulfiram can induce convulsions, cardiac arrhythmias, and myocardial infarction, and the compound has also been associated with polyneuropathy, peripheral neuritis, and skin eruptions (Grant 1986, p. 367; Bouldin et al. 1980, in Neuropathol. Appl. Neurobiol. 8(2):155-160). Disulfiram also causes acneform eruptions, urticaria, lassitude, fatigue, tremor, reduced sexual potency, a garliclike odor of the breath, and fatal hepatotoxicity (Goodman 1980, Pharm. Basic Therapeutics, 6th ed. p. 388; Berlin 1989, in Alcohol 24(3):241-246). A recent study (Rudzki, Rebarrdel, and Grzywa 1989, in Contact Dermatitis 21(2):121-122) described four cases of skin sensitization caused by disulfiram among pharmaceutical workers in Poland. Disulfiram has induced severe and acute hepatotoxicity in many alcoholic patients on alcohol aversion therapy. If the drug is not withdrawn at the earliest signs of liver toxicity, death caused by massive hepatic necrosis occurs (Berlin 1989, in Alcohol 24(3):241-246). A recent review (Dalvi 1988, in Vet. Human Toxicol. 30(5):480-482) of disulfiram's toxicity reports that workers exposed to this substance in the agriculture, rubber, plastics, and lubricating oils industries develop dermatitis, irritation of the mucous membranes, and gastrointestinal and central nervous system disturbances. In animals, liver and renal tubule necrosis and central nervous system demyelination were also reported. This review also reported disulfiram-induced diseases of the thyroid and

gastrointestinal, ocular, and cardiovascular system in workers exposed to disulfiram.

Based on this evidence, OSHA is proposing a PEL of 2 mg/m3 as an 8-hour TWA for disulfiram. The Agency preliminarily concludes that this limit will protect workers in the construction, maritime, and agriculture industries from the significant risk of adverse effects, including dermatitis, liver toxicity, and nervous system effects, that are associated with exposure to disulfiram. OSHA believes that this limit will substantially reduce this significant risk for workers in these sectors and that these effects clearly constitute material impairments of health. In addition, promulgation of this limit will make the PEL for disulfiram consistent across all OSHA-regulated sectors.

ETHION

CAS: 563-12-2; Chemical Formula: C₉H₂₂O₄P₂S₄ H.S. No. 1160

OSHA has no permissible exposure limit for ethion in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 0.4 mg/m³, with a skin notation, for this substance. NIOSH has no REL but concurs (Ex. 8–47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 0.4 mg/m³, and a skin notation, for ethion in the construction, maritime, and agriculture industries. This is the limit recently established for ethion in general industry.

Pure ethion is an odorless and colorless liquid; however, technicalgrade ethion has a very disagreeable odor. Ethion is an insecticide and miticide that is sold in a variety of forms, including 25-percent wettable powder, 2-, 3-, and 4-percent dusts, 5percent granules, in several oil solutions, and in combination with other chemicals (ACGIH 1986, p. 236; Gosselin, Smith, and Hodge 1984, p. II-297). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Like all organophosphorus insecticides, ethion causes cholinesterase inhibition in humans and animals. The oral LD₅₀ in rats is 13 mg/kg, and the dermal LD₅₀ in rabbits is 890 mg/kg (RTECS 1990). Inhalation studies report LC₅₀ values of 710 mg/m³ for female rats exposed to 25-percent wettable powder dust for 1 hour and 7200 mg/m³ for male rats similarly exposed (Niagara Chemical Division, FMC Corp., as cited in ACGIH 1986/Ex. 1–3, p. 236). Instillation of 0.05 ml ethion

in the rabbit eye is immediately irritating but does not cause corneal scarring (ACGIH 1986, p. 238). Dietary studies in rats fed 600, 1000, or 1500 ppm reported complete cholinesterase inhibition; 300 ppm in the diet produced marked cholinesterase inhibition (Association of American Pesticide Control Officials, Inc. 1969, as cited in ACGIH 1986/Ex. 1-3, p. 236). Goats were injected intravenously with 2, 5, or 10 mg/kg doses of ethion. At the 2-mg/kg dose, no signs of toxicity were observed, although blood cholinesterase activity fell to 65 percent of baseline. At higher doses, however, signs of severe toxicity were evident and cholinesterase activity decreased to 10 percent of baseline (in the 5-mg/kg group) or 5 percent (in the 10-mg/kg group) (Mosha and Gyrd-Hansen 1990, in Vet. Hum. Toxicol. 32(1):6-8).

The lowest toxic oral dose of ethion in humans is 100 µg/kg; this exposure caused cholinesterase inhibition (RTECS 1990). Ethion poisonings have been reported in farm workers harvesting grapes and peaches (State of California Department of Industrial Relations, as cited in ACGIH 1986/Ex. 1-3, p. 236).

Based on this evidence, OSHA is proposing a PEL of 0.4 mg/m3 as an 8hour TWA, and a skin notation, for ethion in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that these limits are necessary to protect exposed workers from the significant risks of organophosphate poisoning and cholinesterase inhibition associated with exposure to this substance. The Agency notes this substance's potential for dermal absorption and is proposing a skin notation to protect against the risk of systemic texicity by this route of exposure. OSHA believes that the systemic poisoning and cholinesterase inhibition caused by overexposure to ethion constitute material health impairments. In addition, promulgation of this limit will make the PEL for ethion consistent across all OSHA-regulated sectors.

FENAMIPHOS
CAS: 22224-92-6; Chemical Formula:
C13H22NO2PS
H.S. No. 1173

OSHA has no limit for fenamiphos in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 0.1 mg/m³ for this substance, with a skin notation. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour TWA limit of 0.1 mg/m³, with a skin notation, for fenamiphos in the construction, maritime, and agriculture industries.

This is the limit recently established in general industry.

Fenamiphos, also called Nemacur*, is a tan-colored, waxy solid. It is used as a nematocide and insecticide (ACGIH 1986, p. 265; Farm Chemicals Handbook 1990, p. C207). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Fenamiphos is a cholinesterase inhibitor that produces both central and peripheral cholinergic reactions. The oral LD50 in rats is 8 mg/kg, and the LC50 in the same species is 91 mg/m3 for 4 hours (RTECS 1990). The dermal LDso in rabbits is 178 mg/kg (RTECS 1990). Rats exposed to fenamiphos aerosol at concentrations of 0.03, 0.25, or 3.5 mg/ m3 of air for 3 weeks exhibited no signs of toxicity. At 3.5 mg/m³, however, rats showed significant depression of plasma cholinesterase; 0.25 mg/m3 was the highest no-effect concentration observed (Kimmerle 1982c, as cited in ACGIH 1986/Ex. 1-3, p. 265). Rats fed fenamiphos in the diet at dose levels of 4, 8, 16, or 32 ppm for 90 days showed no effects other than cholinesterase inhibition. Decreases in cholinesterase activity decreased in a dose-dependent manner (Loser and Kimmerle 1968, as cited in EPA 1987 Health Advisory, ODW). Rats were fed fenamiphos at 3, 10, or 30 ppm for 2 years; in the highdose group, statistically significant increases in the weights of the thyroid gland, lungs, and hearts were seen. Cholinesterase activity in the high-dose group was decreased by 28 to 60 percent (Loser and Kimmerle 1968, in EPA 1987). Pregnant rabbits were gavaged with 0.1. 0.3, or 1.0 mg/kg/day fenamiphos on days 6 to 18 of gestation. In the highdose group, fetal death and resorptions were reported, and there was a significant increase in the incidence of skeletal abnormalities in the offspring (MacKenzie et al. 1982, in EPA 1987). Carcinogenicity bioassays in mice and rats were negative.

There are no reports of human poisonings caused by exposure to fenamiphos, and no quantitative data are available relating adverse health effects to measurable airborne concentrations of this substance.

OSHA is proposing a PEL for fenamiphos of 0.1 mg/m³ as an 8-hour TWA in construction, maritime, and agriculture; the Agency believes that this limit is necessary to protect against the significant risk of anticholinesterase effects presented by exposure to this substance. A skin notation is also proposed based on the evidence of fenamiphos's systemic toxicity via percutaneous absorption. The Agency

believes that these limits are necessary to substantially reduce the risk of cholinesterase inhibition, which constitutes a material impairment of health. In addition, promulgation of this limit will make the PEL for fenamiphos consistent across all OSHA-regulated sectors

FENSULFOTHION (DASANIT)
CAS: 115–90–2; Chemical Formula:
C₁₁H₁₇O₄PS₂
H.S. No. 1174

OSHA has no limit for fensulfothion in construction, maritime, or agriculture. The ACGIH has a TLV*-TWA of 0.1mg/m³ for this substance. There is no NIOSH REL, but NIOSH concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour TWA limit of 0.1 mg/m³ for fensulfothion in the construction, maritime, and agriculture sectors. This is the limit recently established for this substance in general industry.

Fensulfothion, also called Dasanit, is a brown liquid at room temperature. It is used as an insecticide and nematocide (ACGIH 1986, p. 266; Hawley's 1987, p. 510). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Fensulfothion is an organophosphorus insecticide that causes cholinesterase inhibition in humans and animals. The oral LD50 in rats is 2 mg/kg, and the dermal LD50 in the same species is 3 mg/kg (RTECS 1990). Rats fed 5 or 20 ppm fensulfothion for 17 months showed increased mortality, and animals in the high-dose group showed reduced growth rates; even at a dietary level of 1 ppm, blood, plasma, and brain cholinesterase activity was inhibited (Hayes 1982, p. 402). Tests in mice and rabbits have shown no embryotoxic, reproductive, or mutagenic effects.

Fensulfothion has been responsible for a number of fatalities in adults and children. A farmer applying fensulfothion developed diarrhea and vomiting and subsequently died; at autopsy, decreased cholinesterase levels and pulmonary edema were seen (Hayes 1982, p. 403). A family of five was poisoned by fensulfothion after it was used as a household pesticide; one of the family members died (Hayes 1982, p. 403). Dermal studies have shown irritation without cholinesterase effects from 2-hour, twice-daily applications of a 5-percent granular formulation to the forearms of three subjects. Systemic absorption through the lungs has been demonstrated after inhalation of

fensulfothion aerosols (ACGIH 1986/

Ex. 1-3, p. 266).

Based on this evidence, OSHA is proposing a PEL of 0.1 mg/m3 TWA for fensulfothion in construction, maritime, and agricultural operations to reduce the significant risks of metabolic effects and skin irritation potentially associated with exposure to this substance. The Agency believes that this limit will substantially reduce these risks among workers in these sectors and that skin irritation and cholinesterase inhibition are material impairments of health. In addition, promulgation of this limit will make the PEL for fensulfothion consistent across all OSHA-regulated sectors.

FENTHION CAS: 55-38-9; Chemical Formula: C10H15O3PS2 H.S. No. 1175

OSHA has no limit for fenthion in the construction, maritime, or agriculture industries. The ACGIH has a TLV*-TWA of 0.2 mg/m³, with a skin notation, for this substance. NIOSH has no REL. OSHA is proposing a limit of 0.2 mg/m3 as an 8-hour TWA, and a skin notation, for fenthion. This is the limit recently established for this substance in general

Fenthion is an oily, yellow- to tancolored liquid that smells slightly like garlic. It is used extensively as a structural control insecticide (ACGIH 1986, p. 267; Hayes 1982, p. 367). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under

the Federal Insecticide, Fungicide, and

Rodenticide Act (FIFRA)

The primary health effect associated with exposure to fenthion is plasma cholinesterase inhibition. The oral LD50 in rats is 180 mg/kg, and the lowest lethal concentration in the same species is 1 g/m3 for 2 hours (RTECS 1990). The dermal LD50 in rats is 330 mg/kg (Farm Chemicals Handbook 1976/Ex. 1-1147b). Rats given single intramuscular injections of 5, 25, or 50 mg/kg fenthion exhibited both enduring electroretinogram changes (ERG) and changes in cholinesterase activity; pseudocholinesterase activity in the plasma dropped to 50 percent of normal on the fourth day after injection. The retinal effects of fenthion persisted for as long as 50 days (Imai 1975/Ex. 1-910). Croups of Donryn rats fed 300 ppm fenthion daily showed symptoms of organophosphate intoxication, including nervousness, general spasms, diarrhea, salivation, and ophthalmologic effects (Kawai, Tojo, Miyazawa et al. 1976/Ex. 1-1157). The no-effect inhalation level for rats is 1 mg/m3 for exposures to the

aerosol of 6 hours/day, 5 days/week for 3 weeks; at a concentration of 3 mg/m3, cholinesterase inhibition was found (Thyssen 1979, as cited in ACGIH 1986/ Ex. 1-3, p. 267). Single and repeated applications of the compound produced no delayed neurotoxic effects in chickens (WHO 1972, as cited in ACGIH 1986/Ex. 1-3, p. 268). Two-year feeding studies of rhesus monkeys showed plasma cholinesterase inhibition at the highest oral dose given, i.e., 0.2 mg/kg/ daily (Rosenblum 1980, as cited in ACGIH 1986/Ex. 1-3, p. 268). Fenthion has caused skin tumors in mice (RTECS 1990).

The lowest lethal dose in humans is reported to be 50 mg/kg (RTECS 1990). Four out of six Nigerian agricultural workers who sprayed fenthion 6 hours/ day for 5 days showed no reduction in cholinesterase activity; however, the other two workers showed cholinesterase activity decreases of 37.5 and 12.5 percent, respectively. Eight of nine U.S. workers spraying fenthion to control mosquitoes showed progressive declines in plasma cholinesterase activity but not in blood cholinesterase

activity (Hayes 1982, p. 369)

Based on this evidence, OSHA is proposing an 8-hour TWA limit of 0.2 mg/m3, with a skin notation, for fenthion in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that these limits are necessary to protect workers in these sectors against the significant risk of cholinergic effects associated with exposure to this substance. A skin notation is proposed because of evidence that fenthion is toxic when absorbed through the skin. OSHA believes that cholinesterase inhibition constitutes a material impairment of health. Promulgation of this limit will also make the PEL for fenthion consistent across all OSHA-regulated

METHOMYL CAS: 16752-77-5; Chemical Formula: C6H10N2O2S H.S. No. 1245

OSHA has no limit for methomyl in the construction, maritime, or agriculture industries. The ACGIH has a TLV*-TWA of 2.5 mg/m3 for this substance. There is no NIOSH REL, but NIOSH concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing a PEL of 2.5 mg/m3 as an 8hour TWA for methomyl in the construction, maritime, and agriculture industries. This is the limit recently established for methomyl in general

Methomyl, also called Lannate, is a white, crystalline solid with a slightly sulfurous odor. This substance is used as an insecticide on vegetables, fruits, and ornamentals (ACGIH 1986, p. 363; Farm Chemicals Handbook 1990, p. C190). When used in pesticidal applications and in accordance with directions on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Methomyl is a cholinesteraseinhibiting carbamate insecticide. The acute oral approximate lethal dose (ALD) for methomyl in rats is 26 mg/kg (Kennedy, Ferenzi, and Burgess 1986, in J. Appl Toxicol. 6(3):145-148). The LC60 in rats is 77 ppm, and the dermal LD50 in rabbits is 5880 mg/kg (RTECS 1990). Applied to the skin of guinea pigs. methomyl caused no appreciable irritation or sensitization. Instillation of a 10-percent solution of methomyl in propylene glycol or of the dry material into rabbit eyes caused mild conjunctivitis without corneal injury. However, marked pupillary constriction, a health effect produced commonly by cholinesterase inhibitors, was observed (E.I. du Pont de Nemours and Co., Inc., as cited in ACGIH 1986/Ex. 1-3, p. 363). Rats fed methomyl at dietary levels of 200 or 400 ppm for 22 months showed decreased hemoglobin levels and, in the high-dose animals, a statistically significant increase in testis to body weight ratios and histopathological changes to the kidneys and spleens (NRC 1983, Vol. 5, p. 58). No depression of cholinesterase activity could be detected in rats fed at levels of 0, 200, 400, or 800 ppm methomyl for 79 days. In dogs, 90-day and two-year feeding studies showed no effects at 0, 50, 100, or 400 ppm; however, animals fed at 1000 ppm did demonstrate toxicity. Similar studies of rats have shown kidney, liver, and spleen damage at higher feeding levels, but the no-effect level for both rats and dogs has been reported to be 100 ppm (Kaplan and Sherman 1977/Ex. 1-337).

In humans, methomyl causes mild conjunctivitis when the dust contacts the eyes (HSDB 1990), and inhalation of powdered methomyl has caused numerous cases of poisoning in workers in several countries (Hayes 1982, p. 456). Eleven of 102 workers in a pesticide plant had been hospitalized for pesticide poisoning, and most of these cases were attributed to methomyl poisoning (Morse et al. 1979, in Hayes 1982, p. 456).

Based on this evidence, OSHA is proposing a PEL of 2.5 mg/m3 (8-hour TWA) for methomyl in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that this limit will protect exposed workers in

these sectors from the risk of cholinesterase inhibition associated with exposure to this substance. The Agency believes that this limit will substantially reduce the significant risk of cholinergic effects, which constitute material impairments of health. In addition, promulgation of this limit will make the PEL for methomyl consistent across all OSHA-regulated sectors.

MONOMETHYL ANILINE CAS: 100–61–8; Chemical Formula:

C₆H₅NHCH₃ H.S. No. 1280

OSHA's PEL for monomethyl aniline (N-methyl aniline) in the construction and maritime industries is 2 ppm, measured as an 8-hour TWA; this limit has a skin notation, indicating that it can readily penetrate the skin. There is no limit for monomethyl aniline in agriculture. The ACGIH has a TLV®-TWA of 0.5 ppm TWA for monomethyl aniline, also with a skin notation. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing to reduce the limit for this substance to 0.5 ppm in the construction and maritime industries, to retain the skin notation, and to extend the limit and notation to agriculture. These are the limits recently established for monomethyl aniline in general industry.

Monomethyl aniline is a colorless liquid that turns reddish-brown after standing. It is used as an acid acceptor, a solvent, and in organic synthesis (ACGIH 1986, p. 375; Hawley's 1987, p.

758).

Monomethyl aniline causes methemoglobinemia in humans and animals. The lowest lethal oral dose in rabbits is 280 mg/kg (RTECS 1990). Treon, Deichmann, Sigmon, and Associates (1949/Ex. 1-676) found that monomethyl aniline applied to the skin of laboratory animals resulted in systemic poisoning. A later study by Treon and Associates (1950/Ex. 1-533) showed that guinea pigs, rabbits, and rats died from 130 or fewer 7-hour exposures to a 7.6-ppm concentration of monomethyl aniline. Before death, these animals showed prostration, labored breathing, and cyanosis, and the rabbits and cats developed methemoglobinemia. In the same study, a monkey survived the same number and length of exposures at 2.4 ppm, and a dog survived 50 exposures to 86 ppm. Autopsy revealed pulmonary effects and liver and kidney damage in these animals (Treon, Sigmon, Wright et al. 1950/Ex. 1-533).

Data on human exposures to monomethyl aniline are scarce. A recent study (Kaminskaia, Soboleva, Kolpakov, Datsishina, and Zhilko 1989, in Vrach-Delo 8:112-113) reports that Russian workers engaged in the production of this substance had a higher than normal incidence of methemoglobinemia, disorders of the pulmonary system, and

cardiovascular changes.

Based on this evidence, OSHA is proposing a 0.5-ppm TWA limit, with a skin notation, for this substance in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that these limits will protect workers in these sectors from the significant risk of metabolic and blood effects, such as methemoglobinemia. that are potentially associated with exposure to monomethyl aniline. The proposed skin notation will protect workers from the risk of systemic poisoning posed by the skin absorption of this substance. OSHA believes that methemoglobinemia constitutes a material health impairment and that the proposed limit will reduce this risk substantially. In addition, promulgation of this limit will make the PEL for this substance consistent across all OSHAregulated sectors.

NITRIC OXIDE

CAS: 10102–43–9; Chemical Formula: NO H.S. No. 2116

In general industry, construction, and maritime, OSHA's permissible exposure limit for nitric oxide is 25 ppm as an 8-hour TWA. There is no limit in agriculture. The ACGIH's TLV*-TWA for nitric oxide is 25 ppm as an 8-hour TWA; NIOSH has a REL of 25 ppm as a 10-hour TWA, and concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 25 ppm for nitric oxide in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Nitric oxide is a colorless nonflammable gas used to make nitric acid. It is also used in rayon bleaching and as a stabilizer (ACGIH 1986, p. 429;

Merck 1983, p. 944).

Exposure to nitric oxide causes central nervous system effects, lung damage, and methemoglobin formation. The LC50 in rats is 1068 mg/m3 (870 ppm) for an unspecified time (RTECS 1990). In rabbits exposed for 15 minutes, the LC50 is 315 ppm (RTECS 1990). Guinea pigs survived exposure to a 175-ppm concentration of nitric oxide for 120 to 150 minutes; no exposure-related effects were seen [NIOSH Criteria Document 1976). Mice exposed to a 2500-ppm concentration of nitric oxide for 6 or 7 minutes showed signs of narcosis; death occurred within 12 minutes (NIOSH/ OSHA Occupational Health Guideline

1981, p. 4). Studies in experimental animals (species unspecified) showed that 6 hours of exposure to a 322-ppm concentration produces a 60 percent methemoglobin level (Paribok and Grokholskaya 1962, in ACGIH 1986, p. 429). Mice exposed to a 10-ppm concentration of nitric oxide for 2 hours/day, 5 days/week for various periods up to 30 weeks showed pronounced emphysematous changes (Holt et al. 1979, in Clayton and Clayton 1981, p. 4101). Nitric oxide is mutagenic both in bacterial and mammalian test systems (RTECS 1987).

In humans, exposure to a 25-ppm concentration of nitrogen oxides can cause pulmonary signs and symptoms after 8 hours; signs and symptoms may not be manifest for as long as 5 to 48 hours after exposure (Braker and Mossman 1980, p. 514). Exposure to a 100- to 150-ppm concentration for 30 to 60 minutes causes delayed-onset pulmonary edema, and at concentrations of 200 to 700 ppm, the pulmonary damage may be severe enough to cause death 5 to 8 hours after exposure (Braker and Mossman 1980, p. 514). Two cases of human poisoning have been reported in which the victims were anesthetized with nitrous oxide contaminated with 1.5 percent nitric oxide. The two individuals developed cyanosis and methemoglobinemia, both of which were attributed to the nitric oxide; one patient died 18 hours after exposure and the other subsequently recovered (NIOSH 1976, pp. 35-36). Methemoglobin levels ranging from 2 to 3 percent have been detected in arc welders exposed to nitric oxide during welding, and levels as high as 44 percent have been seen in silo fillers and other agricultural workers. The normal methemoglobin level is less than 1 percent (Rom 1983, p. 227). Chronic exposure to concentrations of nitrogen oxides (including nitric oxide) too low to cause edema may cause chronic respiratory irritation, corrosion of the teeth, and weakness (Braker and Mossman 1980, p. 515).

Based on this evidence in humans and animals, OSHA preliminarily concludes that nitric oxide causes lung damage and methemoglobinemia in exposed individuals. The Agency believes that, in the absence of a limit for nitric oxide, workers in agriculture are at significant risk of experiencing these effects. OSHA preliminarily finds that the proposed limit of 25 ppm as an 8-hour TWA is necessary to reduce these risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

NITROBENZENE
CAS: 98–95–3; Chemical Formula:
C₆H₅NO₂
H.S. No. 2117

In general industry, construction, and maritime, OSHA's permissible exposure limit for nitrobenzene is 1 ppm (5 mg/ m3) as an 8-hour TWA; this limit also has a skin notation, which indicates that percutaneous absorption is a significant rcute of exposure for this substance. There is no limit for nitrobenzene in agriculture. The ACGIH has a TLV%-TWA of 1 ppm as an 8-hour TWA, also with a skin notation. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the PEL being proposed. OSHA is proposing to establish an 8-hour TWA PEL of 1 ppm, with a skin notation, for nitrobenzene in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Nitrobenzene is an oily, colorless to pale yellow liquid with a strong odor similar to that of bitter almonds.

Nitrobenzene is used in the manufacture of aniline; as a solvent for cellulose esters; in the esterification of cellulose acetate; as an ingredient of soaps, metal polishes, and shoe polishes; in the manufacture of benzidine, quinoline, and azobenzene; as a substitute for almond essence; as a preservative in spray paints; and as an ingredient in perfume (Grayson 1985, p. 790; Hawley's

1987, p. 826; HSDB 1988).

Nitrobenzene causes eye and skin irritation, cyanosis, and blood changes in humans and animals. This substance can also cause kidney and liver effects and central nervous system depression. In addition, testicular damage has been reported in animals. The oral LD50s in rats and mice are 489 mg/kg and 590 mg/kg, respectively (RTECS 1987). The dermal LD50 in rats is 2100 mg/kg, and the lowest lethal dermal dose in rabbits is 600 mg/kg (RTECS 1987). Applied to the eyes or skin of rabbits for 24 hours. nitrobenzene caused only mild irritation (RTECS 1987). The leading toxic effect of nitrobenzene exposure is the formation of methemoglobin, with concomitant cyanosis and the risk of death from respiratory failure (Browning 1965, in HSDB 1988). Rabbits given subcutaneous injections of 0.75 g of nitrobenzene showed marked decreases in hematocrit and hemoglobin levels; a tendency toward spherocytosis was seen, and Heinz bodies were observed in 17 out of 27 of these animals. Other organ changes observed at autopsy included fatty infiltration of the kidneys and liver and nutmeg-sized nodules in the liver (Browning 1965, in HSDB 1988). Rats given intraperitoneal injections of

0.18 g/kg nitrobenzene showed signs of central nervous system depression (Browning 1965, in HSDB 1988). At an oral dose of 200 mg/kg, one rabbit died; 30 hours later, fat deposits were seen in the tissues and gastrointestinal tract (Browning 1965, in HSDB 1988). Degenerative testicular lesions were observed in rats given single oral doses of 50 to 450 mg/kg of nitrobenzene; hepatic centrilobular necrosis was also seen in these animals at autopsy (Beauchamp 1983, in Proctor, Hughes, and Fischman 1988, p. 368; Bond et al. 1981 in HSDB 1988). Chronic exposure to low concentrations of nitrobenzene caused an increase in the number of erythrocytes, methemoglobinemia or hemoglobinemia, albuminuria, and bile in the urine (Browning 1965, p. 300, in HSDB 1988). Rats and mice exposed to nitrobenzene concentrations of 5, 16, or 50 ppm for 6 hours/day, 5 days/week for 90 days showed a dose-related increase in methemoglobinemia and splenic changes; in the high-dose group of rats, degeneration of the seminiferous epithelia was seen (Hamm, Phelps, Raynur, and Irons. Toxicol. 4:181, 1984). Rats given a single oral dose of 300 mg/ kg nitrobenzene showed complete cessation of sperm production 32 to 48 days later; 100 days after the administration of nitrobenzene, more than 90 percent of the seminiferous epithelium had regenerated (Levin, Bosakowski, Earle, and Butterworth 1988, in Toxicol. 53:219-230). Administered subcutaneously to pregnant rats during preimplantation and placentation, nitrobenzene caused a delay in embryogenesis, abnormal placentation, and gross abnormalities in the offspring (National Research Council 1981, Vol. 4, p. 227).

In humans, nitrobenzene causes cyanosis, liver damage, and blood changes. The lowest oral dose reported to be toxic in women is 200 mg/kg; this dose produced behavioral symptoms and affected the cardiovascular and pulmonary systems (RTECS 1987). Nitrobenzene can be absorbed through the skin in lethal amounts (Gosselin, Smith, and Hodge 1984, p. II-214). Ocular effects caused by nitrobenzene exposure include methemoglobinemiainduced brown discoloration of the vessels of the fundus and conjunctiva (Grant 1986, p. 663). Hepatotoxicity, as evidenced by changes in liver function (including hyperbilirubinemia and decreased prothrombin activity), has been seen in humans exposed to nitrobenzene (Beauchamp 1983, in Proctor, Hughes, and Fischman 1988, p. 368). The signs and symptoms of inhalation exposure to nitrobenzene include cyanosis, headache, vertigo,

nausea, visual disturbance, stupor, coma, and death from respiratory failure (Arena 1974, in HSDB 1988). Workers in a chemical plant that had an average nitrobenzene concentration of 6 ppm did not experience signs or symptoms of nitrobenzene poisoning, although one or two cases of headache or vertigo were reported among the 39 workers [Pascéri et al. 1958, in ACGIH 1986, p. 431). Tests of the blood of these workers showed a low level of methemoglobinemia and sulfhemoglobinemia and the presence of some Heinz bodies (Pascéri et al. 1958, in ACGIH 1986, p. 431). When these workers were exposed to nitrobenzene concentrations of close to 40 ppm, however, they did experience toxic episodes (Pascéri et al. 1958, in ACGIH 1986, p. 431). Two cases of occupational overexposure to nitrobenzene have resulted in the development of mild anemia, believed to be of the hemolytic type (Browning 1965, p. 301, in HSDB

Based on this evidence in humans and animals, OSHA preliminarily concludes that nitrobenzene causes eye and skin irritation, cyanosis, blood dyscrasias, central nervous system depression, and splenic and hepatic effects. Accordingly, the Agency believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these effects. OSHA preliminarily finds that the proposed 8-hour TWA PEL of 1 ppm, and a skin notation, are necessary to substantially reduce these significant risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for nitrobenzene consistent across all regulated sectors.

p-NITROCHLOROBENZENE CAS: 100–00–5; Chemical Formula: NO₂C₆H₄Cl H.S. No. 1288

In the construction and maritime industries, OSHA currently has an 8-hour TWA limit of 1 mg/m³, and a skin notation, for p-nitrochlorobenzene (PNCB). There is no limit for this substance in agriculture. The ACGIH has a TLV³-TWA of 0.5 mg/m³ (3 mg/m³), with a skin notation for this substance. NIOSH has no REL for nitrochlorobenzene. The Agency is proposing a 1 mg/m³ 8-hour TWA limit, and a skin notation, for PNCB in agriculture.

Para-Nitrochlorobenzene is a yellow crystalline solid that has a sweet odor. It is used in the manufacture of agricultural chemicals, dyes, and rubber and as a chemical intermediate (ACCIH 1986, p. 321.1(86); Hawley's 1987, p. 269).

The primary hazard associated with exposure to PNCB is

methemoglobinemia. The oral LD50 in rats is 420 mg/kg, and the dermal LD50 in the same species is 16 g/kg (RTECS 1990). PNCB was absorbed through rabbit skin in sufficient quantity to produce methemoglobinemia (Kubota 1960, as cited in ACGIH 1986/Ex. 1-3, p. 432.2). Rusakov, Korotkova, and Bikbulatov (1973/Ex. 1-660) described the development of sensitization in guinea pigs after dermal application of PNCB. A 4-hour inhalation exposure of rats (heads only) showed that the lethal concentration of PNCB is approximately 16.1 mg/L (E.I. du Pont de Nemours & Co., Inc. 1981, as cited in ACGIH 1986/ Ex. 1-3, p. 432.2). Head-only exposures to 0.05, 0.29, or 0.64 mg/L PNCB for 6 hours/day, 5 days/week for 2 weeks resulted in spleen-weight increases and blood effects in all groups. In addition, there were dose-related effects in blood methemoglobin levels (i.e., decreased hemoglobin, hematocrit, and red blood cell count values). Microscopic changes in the spleen, bone marrow, and kidneys were seen in the two higher-dose groups, and both pathological degeneration of the seminiferous tubules and abnormal epididymal sperm contents were also observed in these groups (E.I. du Pont de Nemours & Co., Inc. 1984, as cited in ACGIH 1986/Ex. 1-3, p. 432.2). The Monsanto Company (1981, as cited in ACGIH 1986/Ex. 1-3, p. 432.2) reported that gavage administration of PNCB for 90 days at daily doses of 0.3, 10, or 30 mg/kg to male and female rats produced hemolytic effects and spleen changes at all levels, kidney and liver effects at mid- to high-level doses, and hyperplasia of bone marrow and testicular atrophy at the highest dose (30 mg/kg/day). In 1985, Monsanto reported the results of another gavage study in rats. After 2 years of PNCB feeding at 0.1, 0.7, or 5.0 mg/kg/day, animals in the mid-and high-dose groups exhibited hemolytic effects; in addition, mid- and high-dose groups showed microscopic spleen, kidney, and liver changes and, at the highest dose, bone marrow hyperplasia and testicular atrophy (Monsanto Company 1985, as cited in ACGIH 1986/Ex. 1-3, p. 432.2).

Rats fed PNCB at doses of 0, 0.1, 0.7, or 5 mg/kg/day for up to 2 years showed methemoglobinemia at the two highest levels, and animals in the 5-mg/kg/day group had indications of anemia and pigment accumulation in spleen cells. No treatment-related increase in tumors was observed (Monsanto Company 1985, as cited in ACGIH 1986/Ex. 1-3, p. 432.2). In a dietary cancer bioassay, rats and mice were given PNCB at unspecified levels for 2 years

(Weisberger, Russfield, Homburger et al. p-nitrochlorobenzene exposures only 1978/Ex. 1-535). Only mice were affected, with mice of both sexes showing an increase in vascular tumors at the highest dose and male mice showing an increase in liver tumors at the lowest dose (Weisberger, Russfield, Homburger et al. 1978/Ex. 1-535).

Maternal toxicity was seen in rats given PNCB by gavage at doses of 15 or 45 mg/kg/day on days 9 through 16 of gestation; at the 45-mg/kg level, fetotoxicity and teratogenicity were also observed (Nair, Johannsen, and Schroeder 1985/Ex. 1-752). At 15 mg/kg, maternal toxicity but no fetotoxicity or teratogenic effects occurred: at the lowest dose, the only effect was a small increase in maternal spleen weight. A two-generation reproductive study resulted in a reduced mating index in rats given 0.7 or 5.0 mg/kg/day (Monsanto Company 1984, as cited in ACGIH 1986/Ex. 1-3, p. 432.2). Positive responses were observed in a mutation assay of L5178Y TK mouse lymphoma cells (both with and without metabolic activation) and in a microbial assay of Salmonella strain TA 1535 (in the absence of metabolic activation): however, no evidence of mutagenicity was noted in assays of three other Salmonella strains or in assays of Chinese hamster ovary cells, rat hepatocyte primary culture/DNA repair, or rat bone marrow cell clastogenesis (Monsanto Company 1980-1984, as cited in ACGIH 1986/Ex. 1-3, p. 432.2). PNCB produced DNA damage in the liver. kidney, and brain cells of rats after a single intraperitoneal dose of 30 to 1000 mg/kg (Cesarone, Bolognesi, and Santi 1983/Ex. 1-542) and in cultured hepatocytes at 1.5 hours after a 3-hour treatment (Cesarone, Fugassa, Galle et al. 1984/Ex. 1-541).

p-Nitrochlorobenzene may be absorbed through the lungs and skin in humans to produce methemoglobinemia. Reports of industrial exposures indicate that overexposure causes cyanosis, weakness, and headache (Saita and Moreo 1958/Ex. 1-930; Renshaw and Ashcroft 1926/Ex. 1-522). In a study of workers exposed to average concentrations of PNCB of 55, 125, or 143 ppm and to a 23-ppm concentration of a PNCB-nitrophenol mixture, the authors concluded that the mixed exposure did not produce chronic intoxication but did cause increased methemoglobin, the appearance of Heinz bodies, headache, vertigo, and occasional eczema; these effects could not be attributed definitely either to skin absorption or to the level of PNCB in the mixture (Pascéri, Magos, and Batskor 1958/Ex. 1-521). No data were reported for the

(Pascéri, Magos, and Batskor 1958/Ex. 1-521). Severe allergic dermatitis is reported to be frequent in workers handling PNCB (Gosselin, Smith, and Hodge 1984, p. II-214).

Based on this evidence, OSHA is proposing to extend an 8-hour TWA limit of 1 mg/m3 for pnitrochlorobenzene, and a skin notation, to agricultural workplaces. The Agency preliminarily concludes that these limits are necessary to protect workers in agriculture from the significant risks of methemoglobinemia and changes in the spleen, liver, and kidney possible at higher exposure levels. OSHA is also proposing a skin notation in agriculture because dermal absorption of PNCB has been shown to cause systemic effects in humans and animals. The Agency preliminarily finds that methemoglobinemia and spleen, kidney, and liver damage constitute material impairments of health. In addition, promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

PARATHION CAS: 56-38-2; Chemical Formula: C10H14NO5PS H.S. No. 2122

In general industry, construction, and maritime, OSHA's permissible exposure limit for parathion is an 8-hour TWA of 0.1 mg/m3; this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 0.1 mg/m3. with a skin notation. NIOSH has a 10hour TWA REL of 0.05 mg/m3 for parathion. OSHA is proposing a limit of 0.1 mg/m3 as an 8-hour TWA, and a skin notation, for parathion in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

Parathion is a yellow to deep brown liquid with a faint, garlic-like odor. It is an organophosphorus pesticide that is used as an insecticide and acaricide (Hawley's 1987, p. 874; ACGIH 1986, p. 458). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Parathion causes cholinesterase inhibition in humans and animals. The oral LD50 in rats is 2 mg/kg, and the dermal LD50 in rabbits is 15 mg/kg (RTECS 1990). In rats, the LC50 is 84 mg/ m3 for 4 hours (RTECS 1990). Signs and symptoms of acute exposure in animals include lacrimation, tachypnea,

dyspnea, asynergy, convulsions, diarrhea, depression, paresis, tremors, and prostration (HSDB 1990). The highest dietary concentration that produced no symptoms in rats was 10 ppm for 2 years; a dietary level of 25 ppm caused illness (Lehman 1952, in ACGIH 1986, p. 458). Edson observed that rats given a dose equivalent to 0.42 mg/person/day for 84 days showed no effects but that a 48 percent drop in red blood cell cholinesterase levels occurred when these animals were administered a dose equivalent to 4.2 mg/person/day (Edson et al. 1964, in ACGIH 1986, p. 458). Dogs were given dietary doses of 1, 2, or 5 ppm parathion for 24 weeks; 1 ppm produced a minimal but significant reduction in plasma cholinesterase, and a dose of 2 or 5 ppm reduced plasma cholinesterase levels by 60 to 70 percent (NRC 1977, (Drinking Water and Health

In humans, the lowest lethal oral parathion dose is 171 µg/kg; the lowest lethal dose by dermal absorption is 7143 µg/kg (RTECS 1990). Fatal human poisonings have occurred through ingestion, skin exposure, and inhalation (Proctor, Hughes, and Fischman 1988, p. 391). The signs and symptoms of parathion overexposure include miosis, blurred vision, tearing, chest tightness, wheezing, laryngeal spasms, and excessive salivation (Proctor, Hughes, and Fischman 1988, p. 392). Gastrointestinal effects such as anorexia, vomiting, abdominal cramps, and diarrhea occur within 15 minutes to 2 hours after ingestion of parathion (Koelle 1963, in Proctor, Hughes, and Fischman 1988, p. 392). The most serious effect of exposure is muscle paralysis; central nervous system effects include giddiness, confusion, ataxia, slurred speech, convulsions, and coma (Taylor 1985, in Proctor, Hughes, and Fischman 1988, p. 392). Four volunteers given oral doses of 1 or 2 mg/person/day did not show signs of cholinesterase inhibition but did show distinctly different rates of excretion (Morgan et al. 1977, in Hayes 1982, p. 381). A 12-year old boy exposed to bed sheets contaminated with parathion suffered an elevated blood pressure and respiratory failure and became comatose; the pupils of his eyes were characteristically contracted (Waldbott 1973, in HSDB 1985). In Colombia, 600 people were poisoned by eating bread baked with flour contaminated with parathion; approximately 25 percent of the victims suffered mild poisoning and experienced symptoms such as abdominal pain, headache, blurred vision, tremor, dizziness, and weakness. Others showed profuse sweating, constricted

pupils, and irritability; a few experienced acute pulmonary edema, severe diarrhea, cyanosis, and salivation (Waldbott 1973, in HSDB 1985). Absorption of parathion by inhalation caused a greater depression of cholinesterase activity than absorption by the percutaneous route (Hartwell et al. 1964, in ACGIH 1986, p. 458).

Based on this evidence in humans and animals, OSHA preliminarily concludes that parathion inhibits cholinesterase activity and causes nervous system effects. OSHA preliminarily finds that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that establishing a permissible exposure limit of 0.1 mg/m³ as an 8-hour TWA, and a skin notation, is necessary to significantly reduce the risk of these material health impairments. In addition, promulgation of this limit will make the PEL for parathion consistent across all OSHA-regulated sectors.

PHORATE

CAS: 298–02–2; Chemical Formula: C₇H₁₇O₂PS₃

H.S. No. 1319

OSHA has no limit for phorate in the construction, maritime, or agriculture industry. The ACGIH has limits of 0.05 mg/m³ as an 8-hour TWA and 0.2 mg/m³ as a STEL for phorate, with a skin notation. NIOSH has no REL for this substance but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour PEL of 0.05 mg/m³ and a 15-minute STEL of 0.2 mg/m³, and a skin notation, for phorate in these industries. These limits are the same as those recently promulgated for phorate in general industry.

Phorate is an organophosphate that takes the form of a clear liquid and is used as an insecticide. When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and

Rodenticide Act (FIFRA).

Phorate is a highly toxic cholinesterase inhibitor in animals. The oral LDso in rats ranges from 1.1 to 2.0 mg/kg (Hayes 1982, p. 391) and is 6.6 mg/kg in mice (RTECS 1990). The dermal LDso in rabbits is 99 mg/kg (RTECS 1990). Rats exposed to daily doses of phorate showed cholinesterase inhibition effects above 0.15 mg/kg/day but no effects below this level. The noeffect level in dogs is between 0.01 and 0.05 mg/kg/day (Gaines 1969/Ex. 1–320). In humans, phorate causes classical symptoms of cholinesterase inhibition, including anxiety,

restlessness, headache, emotional and behavioral changes, excessive dreaming, and confusion. In severe cases, exposure to phorate causes loss of muscle coordination, difficulty in breathing, pulmonary rales and rhonchi, convulsions, coma, and death. Several cases of human phorate poisoning have been reported (Hayes 1982, p. 391).

The proposed rule's limits of 0.05 mg/m³ as an 8-hour TWA, supplemented by a STEL of 0.2 mg/m³ and a skin notation, are based on calculations that the noeffect level in humans would lie in the range between 0.21 and 0.7 mg/day, and that use of an appropriate safety factor would suggest an 8-hour limit of 0.05 mg/m³, with a STEL of 0.2 mg/m³, to ensure against excursions greatly in excess of the TWA limit.

OSHA preliminarily finds that limits of 0.05 mg/m3 as an 8-hour TWA and 0.2 mg/m3 as a STEL, and a skin notation, will protect workers exposed to phorate in construction, maritime, and agriculture against cholinesterase inhibition and its associated effects, which include respiratory symptoms, nausea, confusion, and vomiting. The Agency preliminarily concludes that, in the absence of an OSHA limit, phorateexposed employees are at significant risk of experiencing such effects and that establishing a PEL, STEL, and skin notation will substantially reduce these risks. OSHA believes that cholinesterase inhibition and its symptoms clearly constitute material impairments of health. Promulgation of this limit will also make the PEL for this substance consistent across all OSHAregulated sectors.

PROPANE

CAS: 74-98-6; Chemical Formula: C₉H₈ H.S. No. 2134

OSHA is not proposing to extend the limit that currently exists for propane in general industry—1000 ppm—to the construction and agriculture sectors. The only known health effect associated with exposure to this substance is asphyxiation, which occurs at levels that far exceed 1000 ppm.

In 1968, the ACGIH TLV® (and thus OSHA's PEL for general industry) was 1000 ppm as an 8-hour TWA. By 1970, however, the ACGIH had deleted its TLV®-TWA for propane in favor of a listing in Appendix E, "Some Simple Asphyxiants." Since 29 CFR 1926, the construction standards, reference the 1970 TLVs, no numerical limit for propane is currently in effect in construction.

The stated goal of this rulemaking is to achieve consistency across all OSHAregulated sectors; however, there appears to be no health basis for adopting the general industry limit for propane in other sectors. This case is thus the only exception to this stated

objective.

The real hazard with propane is its explosivity, and 29 CFR 1910.110 effectively sets a PEL for propane of approximately 5500 ppm, which is 25% of the LEL (lowest explosive limit) of 22,000 ppm. It is the opinion of the Agency that 1910.110 sufficiently regulates propane, and that a PEL established under 29 CFR 1910.1000 would not therefore reduce a significant health risk.

Because propane is only one of the simple asphyxiants in use in general industry (others are acetylene, argon, helium, hydrogen, propylene, ethanol, etc.), OSHA solicits comment on the policy enunciated here, which is to regulate the simple asphyxiants as explosive substances, i.e., in accordance with their physical, rather than chemical, hazards. Specifically, OSHA seeks comments on whether PELs based on health effects are also needed for these substances to reduce a significant risk to exposed workers.

PROPOXUR (Baygon)
CAS: 114–26–1; Chemical Formula:

C₁₁H₁₅NO₂ H.S. No. 1337

OSHA has no limit for propoxur in the construction, maritime, and agriculture industries. The ACGIH has established an 8-hour TLV*-TWA of 0.5 mg/m³ for this substance. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour TWA limit of 0.5 mg/m³ for propoxur in the construction, maritime, and agriculture industries. This limit is the same as the limit recently promulgated for general industry.

Propoxur is a white, odorless, crystalline carbamate. It is used as an insecticide, particularly for flea and tick control on animals, and as a molluscicide (ACGIH 1986, p. 499; Hawley's 1987, p. 660). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Like all carbamate insecticides, propoxur causes reversible cholinesterase inhibition. The oral LD 508 in male and female rats are 83 and 86 mg/kg, respectively; for both sexes, the dermal LDso is greater than 2400 mg/kg (Gaines 1969/Ex. 1–320). Dietary studies in rats at levels of 7.5 mg/kg/day for 28 days or at 800 ppm for 3 months found no adverse effects (Association of

American Pesticide Control Officials, Inc. 1966/Ex. 1–1011). Rats were exposed to propoxur concentrations of 5, 7, 18.7, or 31.7 mg/m³ 6 hours/day, 5 days/week for 12 weeks; animals in the high-dose group showed depressed red blood cell and brain cholinesterase levels, and plasma cholinesterase was depressed by as much as 20 to 30 percent (Association of American Pesticide Control Officials, Inc. 1966/Ex. 1–1011).

In humans, a few cases of mild propoxur poisoning have been reported among sprayers of this insecticide and among residents of propoxur-treated homes (Vandekar, Hedayat, Plestina, and Ahmady 1968/Ex. 1-679). Based on a survey of 696 pet care facility workers, Hines et al. (American Industrial Hygiene Association Journal 50:466-472, 1989) reported an association between exposure to propoxur and an increased frequency of convulsions, muscle twitches, fatigue, and headaches. In a study of human volunteers, a single oral dose of 1.5 mg/kg propoxur caused a depression in red blood cell cholinesterase and gastrointestinal symptoms that disappeared 2 hours after ingestion. Oral doses of 0.75 to 1.0 mg/ kg produced no symptoms but did depress erythrocyte cholinesterase (Vandekar, Plestina, and Wilhelm 1971/ Ex. 1-680).

OSHA is proposing an 8-hour TWA of 0.5 mg/m³ for propoxur in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risk of cholinesterase inhibition associated with exposure to this substance. OSHA believes that cholinesterase inhibition is a material health impairment. Promulgation of this limit will also make the PEL for this substance consistent across all OSHA-regulated sectors. RONNEL

CAS: 299-84-3; Chemical Formula: (CH₃O)₂PSOC₆H₂Cl₃ H.S. No. 1349

OSHA has a limit of 15 mg/m³ TWA for ronnel in construction and maritime operations. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 10 mg/m³ for this substance. NIOSH has no REL for this substance but concurs (Ex. 8-47, Table N1) with the limit being proposed. OSHA is proposing an 8-hour TWA of 10 mg/m³ for ronnel in agriculture, construction, and maritime. This limit is the same as the PEL recently promulgated for ronnel in general industry.

Ronnel is a white powder. It is used as an insecticide (ACGIH 1986, p. 513; Farm Chemicals Handbook 1990, p. C252).

When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Ronnel is an indirect cholinesterase inhibitor that affects the blood plasma rather than red cell acetylcholinesterase (Plapp and Casida 1958a/Ex. 1-657). The acute oral LDso in rats is reported as 1250 and 2630 mg/kg for males and females, respectively. The oral LDso in dogs is greater than 500 mg/kg (McCollister, Oyen, and Rowe 1959/Ex. 1-594). Two-year dietary studies of rats fed up to 50 mg/kg/day showed no effect on growth rate, food consumption. survival, or hematopoiesis (McCollister, Oyen, and Rowe 1959/Ex. 1-594). In a study by Gladenko and Stuk (1972, as cited in ACGIH 1986/Ex. 1-3, p. 513). albino rats developed clinical symptoms of motor irritation, tremor, increased auditory and tactile sensitivity. lacrimation, and salivation within 2 weeks of exposure to ronnel concentrations of between 164 and 328 mg/kg; some animals died during the latter part of the study. At exposures below 16.4 mg/kg, no ill effects were observed (Gladenko and Stuk 1972, as cited in ACGIH 1986/Ex. 1-3, p. 513). A 2-year feeding study in dogs exposed to daily doses of 10 mg/kg showed no ill effects except cholinesterase depletion (Worden, Noel, and Mawdesley-Thomas 1972/Ex. 1-583). Oral administration of ronnel to pregnant rats and rabbits has been associated with adverse reproductive and developmental effects (RTECS 1990).

Patch tests of 50 human subjects showed that ronnel has no skinsensitizing potential (McCollister, Oyen, and Rowe 1959/Ex. 1–594).

OSHA is proposing an 8-hour TWA PEL of 10 mg/m³ for ronnel in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risk of cholinergic effects associated with exposure to this substance. OSHA believes that this limit will substantially reduce this significant risk and that cholinesterase inhibition constitutes a material health impairment. Promulgation of this limit will also make the PEL for ronnel consistent across all OSHA-regulated sectors.

SULPROFOS

CAS: 35400-43-2; Chemical Formula: C₁₂H₁₉O₂PS₃

H.S. No. 1380

OSHA has no limit for sulprofos in the construction, maritime, or agriculture industry. The ACGIH has an exposure

limit of 1 mg/m³ as an 8-hour TWA.

NIOSH has no REL for this substance
but concurs (Ex. 8-47, Table N1) with
the limit being proposed. OSHA is
proposing an 8-hour TWA of 1 mg/m³
for sulprofos in agriculture, construction,
and maritime. This limit is the same as
that recently promulgated for general
industry.

Sulprofos, also known as the insecticide Bolstar, is a tan liquid (ACGIH 1986, p. 547). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Like all organophosphate pesticides, sulprofos inhibits the enzyme cholinesterase. Kimmerle (1982b, as cited in ACGIH 1986/Ex. 1-3, p. 547) conducted an extensive animal study on the effects of sulprofos. He reported that the acute toxicity of sulprofos is speciesdependent: rats have an oral LD50 of 100 to 300 mg/kg and mice have an oral LD50 of 1600 to 1800 mg/kg. The reported dermal LDsos are greater than 1000 mg/ kg in rats and 800 to 1000 mg/kg in rabbits. In rabbits, sulprofos did not irritate the skin or eyes, and it had no dermal sensitization effects in guinea pigs. Inhalation studies showed no fatalities in rats exposed to sulprofos aerosol concentrations of up to 4130 mg/ m3 over a period of 4 hours. In a 3-week inhalation study in which rats were exposed to aerosol concentrations of 6. 14, or 74 mg/m³, the two highest concentrations produced cholinergic symptoms; no observable effects were seen at the lowest concentration. Twoyear feeding studies by Kimmerle (1982b, as cited in ACGIH 1986/Ex. 1-3, p. 547) in dogs, rats, and mice showed that sulprofos concentrations of 150 ppm, 250 ppm, or 400 ppm were tolerated by all species, with no sulprofos-related tissue changes, signs of toxicity, or oncogenic effects. The overall NOELs were 10 ppm in dogs, 6 ppm in rats, and 2.5 ppm in mice. Kimmerle's ingestion studies in rats and rabbits dosed at levels of 3, 10, or 30 mg/kg/day of sulprofos showed no embryotoxic or teratogenic effects among the offspring of these animals. and a three-generation diet study in rats also produced no adverse reproductive effects. Mutagenic studies reported by the same author in mice were negative. Separate subacute inhalation studies also showed no effects on blood cholinesterase levels in rats exposed to 6 mg/m³ (Zielhuis and van der Kreek 1979/Ex. 1-613). There are no reported cases of poisoning in humans (ACGIH 1986/Ex. 1-3, p. 547).

OSHA is proposing an 8-hour TWA limit of 1 mg/m3 for sulprofos in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that this limit will protect workers in these sectors from the significant risk of cholinesterase inhibition, the most sensitive indicator of exposure to this substance. The Agency believes that this limit will substantially reduce this significant risk, and that cholinesterase inhibition constitutes a material impairment of health. Promulgation of this limit will also make the PEL for this substance consistent across all OSHA-regulated sectors.

TERPHENYLS
CAS: 26140-60-3; Chemical Formula:
C₁₆H₁₄

H.S. No. 1384

OSHA's PEL in construction and maritime for the terphenyls is 1.0 ppm as a ceiling limit. There is no limit in agriculture. The ACGIH has a 0.5-ppm ceiling limit for these substances.

NIOSH has no REL but concurs (Ex. 8–47, Table N1) with the limit being proposed. OSHA is proposing a PEL in construction, maritime, and agriculture of 0.5 ppm as a ceiling limit for terphenyls. This limit is the same as that recently promulgated for general industry.

Terphenyls are colorless or light yellow solids; commercial preparations contain mixtures of ortho-, meta-, and paraterphenyls. Terphenyls are used as heat transfer fluids and reactor coolants (ACGIH 1986, p. 559).

The terphenyls are primary irritants that cause eye, skin, and respiratory tract irritation. Haley, Detrick, Komesu et al. (1959/Ex. 1-326) reported that mixtures of terphenyls caused conjunctival irritation when instilled into the eyes of rabbits and damaged guinea pig skin following intracutaneous injection. Cornish, Bahor, and Ryan (1962/Ex. 1-410) determined LDso values of 1900, 2400, and greater than 10,000 mg/kg for the ortho-, meta-, and paraterphenyls, respectively. These authors also conducted 30-day feeding studies of rats involving doses of 250 or 500 mg/ kg/day of the individual terphenyl isomers. Rats fed ortho-terphenyl showed elevated liver and kidney weight ratios; rats fed meta-terphenyl displayed elevated kidney weight ratios only; and rats fed para-terphenyl showed no elevation in liver or kidney weight ratios. Two studies by Petkau and Hoogstraaten (1965/Ex. 1-432) and Young, Petkau, and Hoogstraaten (1969/ Ex.1-459) have shown that the terphenyls have nephrotoxic effects and

cause hepatic damage in rats fed 33 mg/kg/day.

Inhalation by rats of high concentrations (66 to 339 ppm) of mixed or individual isomers for periods ranging from 1 hour to 14 days resulted in tracheobronchitis, pulmonary edema, and death at higher doses (Proctor. Hughes, and Fischman 1988, p. 459). Adamson, Bowden, and Wyatt (1969/Ex. 1-293) published a study in which rats exposed to terphenyl aerosols for 7 hours per day at a concentration of 50 mg/m3 (approximately 5 ppm), for a period of 8 days developed morphological changes in their pulmonary cell mitochondria; the number of vacuolated mitochondria was directly related to duration of exposure.

Weeks (1971/Ex. 1-580) and Weeks and Lentle (1970/Ex. 1-682) conducted a clinical survey of 47 workers with ongoing exposure to terphenyl coolant in a nuclear facility. The study represented 122 person-years of occupational exposure, with durations of exposure ranging from 6 months to 7 years. The airborne concentrations of terphenyl varied, measuring 0.094 mg/m3 in general working areas and up to 0.89 mg/m³ in areas with organic piping equipment. The terphenyl coolant was determined to be a primary irritant, even in those workers wearing protective clothing, because skin moistness increased dermal sensitivity to the terphenyls (Weeks 1971/Ex. 1-580; Weeks and Lentle 1970/Ex. 1-682). Testa and Masi (1964/Ex. 1-578) reported that, at concentrations above 10 mg/m3 (approximately 1 ppm, the current OSHA ceiling limit in construction and maritime), workers reported both eye and respiratory irritation.

OSHA is proposing a ceiling limit of 0.5 ppm for the terphenyls in construction, maritime, and agriculture. The Agency preliminarily concludes that this limit will protect workers in these sectors against the significant risk of primary irritation of the eyes, skin, and upper respiratory tract potentially associated with exposure to very low airborne levels of the terphenyls. The Agency believes that this limit will substantially reduce these significant risks and that primary irritation and metabolic effects constitute material health impairments. Promulgation of this limit will make the PEL for this substance consistent across all OSHAregulated sectors.

m-TOLUIDINE
CAS: 108-44-1; Chemical Formula:
C7H₉N
H.S. No. 1401

OSFIA has no PEL for m-toluidine in the construction, maritime, and agriculture industries. The ACGIH has a 2-ppm 8-hour TLV*-TWA, with a skin notation. NIOSH has no REL for this substance. OSHA is proposing a PEL of 2 ppm as an 8-hour TWA, and a skin notation, for this substance in the construction, maritime, and agriculture industries. This is the limit recently promulgated for m-toluidine in general industry.

m-Toluidine is a light yellow liquid. It is used as an intermediate in the manufacture of dyes and other chemicals (ACGIH 1986, p. 589).

Like other aniline derivatives, mtoluidine produces methemoglobinemia in humans and experimental animals. The oral LD50s in rats and mice are 450 and 740 mg/kg, respectively (RTECS 1990). When m-toluidine was tested on the eyes and skin of rabbits, moderate to strong irritation resulted (NIOSH 1979b, as cited in ACGIH 1986/Ex. 1-3, p. 589). A mean maximal methemoglobinemia of 60.2 percent was reported to occur following the intravenous administration of 27 mg/kg m-toluidine in cats (McLean, Starmer, and Thomas 1969/Ex. 1-425). Rodent carcinogenicity studies cited by the ACGIH (1986/Ex. 1-3, p. 589) were either inconclusive or negative; however, NIOSH (Ex. 8-47, Table N-2) pointed out in the prior rulemaking that this substance is an aromatic amine like o- and p-toluidine, both of which are carcinogenic.

The effects in humans of exposure to m-toluidine, when it is either absorbed through the skin or delivered via inhalation, are hematuria and methemoglobinemia. Exposure to 40 ppm for 60 minutes causes severe poisoning (Goldblatt 1955/Ex. 1–417). There are no epidemiological studies of workers exposed only to m-toluidine (ACGIH 1986/Ex. 1–3, p. 589).

OSHA is proposing a 2-ppm 8-hour TWA and a skin notation for mtoluidine in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that this limit will protect workers from the significant risk of metabolic effects, such as hematuria and methemoglobinemia, associated with exposure to m-toluidine. OSHA believes that hematuria. methemoglobinemia, and the other metabolic effects associated with exposure to m-toluidine constitute material impairments of health. Promulgation of this limit will also make the PEL for this substance consistent across all OSHA-regulated sectors. 2,4,6-TRINITROTOLUENE (TNT) CAS: 118-96-7; Chemical Formula: C7H5N3O6

H.S. No. 1413

OSHA's PEL for 2,4,6-trinitrotoluene (TNT) in construction and maritime is 1.5 mg/m3 as an 8-hour TWA, with a skin notation. There is no limit in agriculture. The ACGIH has a TLV®-TWA of 0.5 mg/m3, also with a skin notation, for this chemical. NIOSH has no REL for this substance but concurs (Ex. 8-47, Table N-1) with the limit being proposed. OSHA is proposing an 8-hour TWA of 0.5 mg/m3, and a skin notation, for this substance in construction, maritime, and agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated sectors.

TNT occurs as yellow, needle-like crystals. It is used as a high explosive

(ACGIH 1986, p. 610).

TNT causes destruction of the red blood cells and methemoglobinemia in experimental animals. The oral LD50s in rats and mice are 795 and 660 mg/kg, respectively. Rats given 50 mg/kg per day in the diet showed anemia, lesions of the spleen, liver and kidney damage, and bladder carcinoma (Proctor, Hughes, Fischmann 1988, p. 497). In a study by Dilley et al. (cited in HSDB 1990), rats were given 0, 0.002, 0.01, 0.05, or 0.25 percent TNT in the diet for 13 weeks. Rats receiving the highest dose exhibited anemia with reduced erythrocytes, hemoglobin, and hematocrit, as well as reduced testicular size; all effects except the testicular atrophy were reversible after the exposure period.

The ACGIH's limit was selected on the basis of health surveys conducted among occupationally exposed workers. Fairhall (1957e, as cited in ACGIH 1986/ Ex. 1-3, p. 610) describes dermatitis, cyanosis, gastritis, acute yellow atrophy of the liver, and aplastic anemia as possible effects of exposure to TNT. According to Soliman (1957/Ex. 1-991), blood cell destruction, leucocytosis or leucopenia, and varying degrees of central nervous system change (probably resulting from anoxia), peripheral neuritis and muscular pain, cardiac muscular and menstrual irregularities, and urinary and renal irritation can also occur as a consequence of TNT exposure. TNT has irritant properties and may cause sneezing, sore throat, or skin irritation (von Oettingen 1941/Ex. 1-874).

A study by Goodwin (1972/Ex. 1-556) revealed 36 cases of liver damage in a munitions plant where workers were exposed to a mean air level of 2.38 mg/m³ TNT over a period of 20 years.

Another study (Morton, Ranadive, and Hathaway 1976/Ex. 1–566) found elevated levels of liver enzymes in 43 TNT shell-packers and loaders who worked where TNT exposures ranged from 0.3 to 0.8 mg/m3 over a period of 5 months. In 1975, Djerassi and Vitany (Ex. 1-550) published a paper describing hemolytic episodes in three TNT workers with glucose-6-phosphate dehydrogenase deficiency; although these workers were from Iraq, where C-6-PDase deficiency has a high (25 percent) frequency of occurrence, the study is also of concern for other workers having a high frequency of G-6-PDase deficiency. TNT has been reported to cause cataracts among workers exposed above 1 mg/m3 for 5 years or more (Proctor, Hughes and Fischmann 1988, p. 496). The cataracts induced by TNT may not regress after the cessation of exposure.

OSHA is proposing an 8-hour TWA of 0.5 mg/m3 for 2.4,6-trinitrotoluene, and a skin notation, in the construction, maritime, and agriculture industries. The Agency preliminarily concludes that this limit is necessary to protect workers in these sectors against the significant risk of liver damage, hemolytic effects, and cataract formation potentially associated with exposure to TNT. OSHA believes that this limit will substantially reduce these significant risks and that liver damage and hemolysis constitute material health impairments. Promulgation of this limit will also make the PEL for this substance consistent across all OSHAregulated sectors.

WARFARIN
CAS: 81-81-2; Chemical Formula:
C₁₉H₁₉O₄
H.S. No. 2168

In general industry, construction, and maritime, OSHA's permissible exposure limit for warfarin is 0.1 mg/m³ as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV*–TWA of 0.1 mg/m³ for this substance; NIOSH has no REL but concurs (Ex. 8–47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL in agriculture of 0.1 mg/m³ for warfarin. This is the limit recently established for warfarin in general industry.

Warfarin is an odorless, colorless to white, crystalline powder. It is available commercially as a dust or liquid concentrate and in various formulations with other pesticides (HSDB 1987; Hayes 1982, p. 508). Warfarin is primarily used as a rodenticide; it is also used in medicine as an anticoagulant (HSDB 1987). When used in pesticidal applications and in accordance with the label, this substance is regulated by the

EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

In both animals and humans, warfarin acts on the liver to inhibit prothrombin formation, which interferes with blood clotting; warfarin also damages the blood vessels directly. The lowest reported oral LD₅₀ in rats is 1500 μg/kg, and the LC50 in the same species is 320 mg/m3 (RTECS 1990). The dermal LD50 in rats is 1400 mg/kg (RTECS 1990). Although a large single dose of warfarin can cause poisoning, this substance is most toxic when ingested daily in small amounts over a 5- to 7-day period. Rats and mice die after ingesting 1 mg/kg/ day for 6 days (Booth 1982, in HSDB 1987). The clinical signs of lethal warfarin poisoning include massive hemorrhage, visible hematomas under the skin and around the joints, and bloody discharges from body orifices. Shock, weakness, and labored breathing may also occur (Booth 1982, p. 955). Intramuscular exposure to 10 mg/kg on days 8 through 28 of pregnancy caused stillbirths and developmental abnormalities in the offspring of dosed rabbits (RTECS 1990).

In humans, the lowest reported lethal dose is 6667 µg/kg (RTECS 1989). Several days of warfarin administration are usually required to deplete the body's stores of clotting factor and to produce an anticoagulant effect. A single large dose can cause the anticoagulant effect after a latency period of several days (Wisconsin Alumni Research Foundation 1951: Back et al. 1978). Toxic doses of warfarin also produce dilation and engorgement of blood vessels and increased capillary fragility, which may further increase the risk of hemorrhage (Hayes and Gaines 1950; Hayes 1963; Heisey et al. 1956). Except for abnormal bleeding, warfarin has few toxic effects, although anorexia, nausea, vomiting, diarrhea, and skin lesions may occur in some individuals (Goodman 1975, p. 1359). As in animals,

warfarin is most toxic when ingested in small doses over a period of 5 to 6 days; 1 to 2 mg/kg/day for 6 days is estimated to be lethal (Klaassen, Amdur, and Doull 1986, p. 564). Warfarin can be absorbed through the skin in toxic amounts. A 23year old farmer was exposed to a 0.5percent warfarin sodium salt by skin contact for several hours on ten occasions during a 24-day period. On day 26, he developed gross hematuria. On day 27, hematomas appeared on his arms and legs and he complained of dull pain in both sides of his groin area. On day 30, the hematuria resolved and he developed nosebleeds. The patient recovered fully following administration of vitamin-K (Fristedt and Sterner 1965, p. 205). Warfarin causes fetotoxic and teratogenic effects in the offspring of women taking this substance as an anticoagulant during pregnancy; many cases of stillbirths and deformities have been attributed to the therapeutic use of warfarin (Hall et al. 1980).

Based on this evidence, OSHA preliminarily concludes that, in the absence of a permissible exposure limit, workers in agriculture are at significant risk of experiencing capillary fragility and hemorrhage, the principal effects of warfarin exposure. The Agency believes that establishing an 8-hour TWA PEL of 0.1 mg/m³ will substantially reduce this risk. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

Preliminary Conclusions for the Group of Biochemical/Metabolic Toxins. For the class of toxic substances having biochemical/ metabolic effects, OSHA preliminarily concludes that occupational exposure presents significant risks to health. The effects associated with exposure to these substances (which inhibit cholinesterase activity, interfere with the blood's ability to carry oxygen, or produce Antabuse-like symptoms and signs)

range from nausea, bronchoconstriction, cardiac irregularities, neurobehavioral effects, and unconsciousness to coma and death, depending on the severity of the exposure. OSHA believes that all of these symptoms and signs constitute material health impairments.

Accordingly, the Agency believes that establishing the proposed limits for this group of toxicants is necessary to substantially reduce these significant occupational risks among workers in construction, maritime, and agriculture.

13. Substances for Which Proposed Limits Are Based on Avoidance of Sensitization Effects

Introduction. OSHA is proposing limits for 12 substances on the basis of their ability to cause pulmonary or skin sensitization. Table C13-1 lists OSHA's current permissible exposure limits (PELs) for these substances in construction and maritime; there are no PELs in agriculture for this group of sensitizers. Table C13-1 also shows the 1987-1988 ACGIH TLV® and the NIOSH recommended exposure limit (REL) for these substances. The last column on this table shows the limits for these substances recently established by OSHA in general industry; these are the limits being proposed for these substances in construction, maritime, and agricultural workplaces. The CAS and HS numbers for these substances are also shown in Table C13-1

Description of the Health Effects. A sensitization reaction, also known as an allergic reaction, is defined as an adverse response to a chemical following a previous exposure to that substance or to a structurally similar one (Klaassen, Amdur, and Doull 1986/Ex. 1–99). A person who suffers an allergic reaction to a chemical is said to have become sensitized to that substance.

TABLE C13-1. SUBSTANCES FOR WHICH PROPOSED LIMITS ARE BASED ON AVOIDANCE OF SENSITIZATION

	H.S. No./chemical name	CAS No.	Current OSHA PEL in construction and maritime*	1987-1988 ACGIH TLV***	NIOSH REL***	Proposed OSHA PEL in construction maritime, and agriculture*
1066	Captafol (Difolatan)	2425-06-1		0.1 mg/m³ TWA, Skin.		0.1 mg/m³ TWA.
1100	Cobalt metal, dust and fume (as Co)	7440-48-4	0.1 mg/m ³ TWA	A STATE OF THE PARTY OF THE PAR		0.05 mg/m³ TWA.
1222	Isophorone diisocyanate	4098-71-9				0.005 pmm TWA. 0.02 pmm STEL, Skin.

TABLE C13-1. SUBSTANCES FOR WHICH PROPOSED LIMITS ARE BASED ON AVOIDANCE OF SENSITIZATION—Continued

H.S. No./chemical name	CAS No.	Current OSHA PEL in construction and maritime*	1987-1988 ACGIH TLV***	NIOSH REL***	Proposed OSHA PEL in construction maritime, and agriculture*
1329 Picric acid	88-89-1	0.1 mg/m³ TWA, Skin.	0.1 mg/m³ TWA 0.3 mg/m³ STEL, Skin.		0.1 mg/m³ TWA, Skin.
2133 Platinum soluble salts (as Pt)	7440-06-4 7440-16-6	0.002 mg/m³ TWA 0.1 mg/m³ TWA	0.002 mg/m3 TWA		0.002 mg/m³ TWA. 0.1 mg/m³ TWA.
1348 Rhodium, soluble compounds (as Rh)	7440-16-6 1395-21-7	0.001 mg/m³ TWA			
1398 Toluene-2,4-diisocyanate (TDI)	584-84-9	0.02 ppm Ceiling		0.005 pmm TWA 0.02 pmm Ceiling (10-min).	0.005 ppm TWA. 0.02 ppm STEL

*OSHA's PELs do not currently apply in Agriculture; OSHA's TWA limits are for 8-hour exposures; its STELs are for 15 minutes unless otherwise specified; and its ceilings are peaks not to be exceeded for any period of time.

**The ACGIH TLV*—TWA is for an 8-hour exposure; its STELs are 15-minute limits not to be exceeded more than 4 times in any working day, with a minimum of 60 minutes between successive STEL exposures; and its ceilings are peaks not to be exceeded for any period of time.

***NIOSH TWA limits are for 10 hour/day, 40 hour/week exposures unless otherwise specified, and its ceilings are peaks not to be exceeded for any period of time unless a duration is specified in parentheses.

**Compliance with the subtilisins PEL is assessed by sampling with a high volume sampler (600–800 liters per minute) for at least 60 minutes.

Sensitization is the result of an immune system reaction to a substance: although the initial exposure does not generate an immediate response, the immune system "remembers" the substance and reacts strongly at the next encounter. A related phenomenon is cross-sensitization. Crosssensitization occurs when exposure to one substance elicits a sensitization reaction not only on subsequent exposure to the same substance but also on exposure to a different substance (usually one with a similar chemical structure).

The toxic manifestations of sensitization reactions vary in both location and severity. In humans, common target organs are the skin and the eyes; typical allergic conditions in these organ systems are allergic contact dermatitis and conjunctivitis, respectively. The respiratory system can also be sensitized; the resulting pathologies include bronchitis and asthma (Dean, Murray, and Ward 1986/ Ex. 1-195). These allergic reactions are mediated by the two immunoglobulins IgD or IgE. The involvement of IgD results in delayed contact dermatitis. In contrast, IgE-mediated reactions cause very severe and potentially fatal effects, such as acute asthmatic attacks, urticaria, and anaphylactic shock. The unpredictability and potential seriousness of sensitization reactions demand that exposures to sensitizing substances be carefully controlled.

Sensitivity to a chemical frequently persists throughout the lifetime of an individual; in some cases, however, sensitization disappears over time. Sensitization symptoms are not observed after exposure to the sensitizing agent (or to a structurally

similar chemical) has been discontinued. Although it is possible to treat some allergies, avoidance is considered the best way-and is sometimes the only

way-to regain good health.

An additional cause for concern about exposure to sensitizing chemicals is recent evidence that residual respiratory symptoms may continue even after exposure is discontinued. For example, in the case of toluene-2,4-diisocvanate (TDI), studies by Weill, Butcher, Dharmarajan et al. (1981/Ex. 1-1188) and Innocenti, Franzinelli, Sartorelli et al. (1981/Ex. 1-180) found that sensitized workers may exhibit decreased pulmonary function or chronic bronchitis for as long as three and onehalf years after cessation of exposure.

Dose-Response Relationships and Sensitization Effects. Like other toxic effects, allergic reactions are doserelated; that is, in response to larger doses of the substance, increasing numbers of subjects become sensitized and the subsequent reactions become more severe. The time course of sensitization for any one individual is unpredictable. Some individuals are sensitized after only one exposure; others remain resistant to sensitization after a lifetime of exposure. Different people are generally sensitive to different substances, although some substances are more universally reactive than others, such as the active agent in poison ivy. Various parameters influence the likelihood of sensitization by a particular chemical; these include such factors as "the nature of the chemical, concentration, type of exposure, genetic susceptibility and nongenetic idiosyncrasies" (Emmett 1986/Ex. 1-226). The sensitization reactions observed in occupational

settings are often the result of dermal or inhalation exposure.

For most of the substances in this group, OSHA is proposing limits in construction, maritime, and agriculture on the basis of health surveys and reports of occupationally exposed populations; the proposed limits are those recently established by OSHA for workplaces in general industry. The studies available indicate that exposures to airborne concentrations of these substances that are below a certain no-effect level generally do not cause sensitization in individuals. Where human data were absent or sparse, OSHA relied on animal evidence to determine where the proposed limit should be set. Sensitization reactions in animals are generally good predictors of immune system reactions in humans because chemically induced immunological sensitization in laboratory animals involves the same mechanism as in humans (that is, immune reactions in animals can be mediated by either IgD or IgE immunoglobulins).

The discussions below describe the evidence and explain OSHA's rationale for proposing these limits for these substances. These discussions illustrate the nature of the risk confronting exposed employees in construction, maritime, and agriculture and indicate the extent to which the risk of developing immune sensitization will be reduced among workers in these sectors by the promulgation of the proposed

CAPTAFOL (DIFOLATAN) CAS: 2425-06-1; Chemical Formula: C10H9CL4NO2S H.S. No. 1066

OSHA has no permissible exposure limit for captafol in the construction, agriculture, and maritime industries. The ACGIH has a TLV*-TWA of 0.1 mg/m³, with a skin notation, for captafol; there is no NIOSH REL. The Agency is proposing a TWA PEL of 0.1 mg/m³ for captafol in the construction, agriculture, and maritime industries. In the prior rulemaking, NIOSH (Ex. 8-47, Table N6A) concurred that this limit was appropriate. The 0.1 mg/m³ 8-hour TWA PEL was recently established in general industry.

Captafol is a colorless to white, crystalline solid with a faint and characteristically pungent odor. This substance was formerly used as a fungicide in agriculture; however, EPA canceled the registration for this substance in 1987 on the basis of captafol's carcinogenicity in laboratory animals (HSDB 1990; ACGIH 1986, p. 97). Although OSHA is not aware of any current use of captafol in those sectors being covered by this rule, OSHA includes this substance for the sake of completeness and to ensure that any occupational exposure to captafol of which OSHA may not be aware is covered by this rule.

Captafol is a skin sensitizer in guinea pigs and a teratogen in several species of animals (Clayton and Clayton 1981, p. 2705). The oral LD50 in rats is 2500 mg/kg (RTECS 1990). Rats fed captafol at dietary levels of 1500 or 5000 ppm had enlarged livers and, at the higher dose, an increase in mortality (Hayes 1982, p. 583). At autopsy, both liver and kidney damage were seen (Hayes 1982, p. 583). Dogs fed 100 or 300 mg/kg/day vomited and had diarrhea for the first 4 weeks and subsequently became slightly anemic and developed enlarged kidneys and livers. At 10 mg/kg/day, no effects were seen (Hayes 1982, p. 583). Tested in rats, rabbits, and hamsters by the oral or intraperitoneal routes of administration. captafol caused embryotoxic, developmental, or reproductive effects (RTECS 1990). Captafol is mutagenic in bacterial and mammalian test systems (RTECS 1990).

In humans, captafol is a known skin and respiratory sensitizer (Clayton and Clayton 1981, p. 2705). Both agricultural and non-agricultural workers have developed captafol-induced dermatitis; the rash produced in these cases resembles that of poison oak (Clayton and Clayton 1981, p. 2710). In one case, a welder brushed up against bags of captafol at a pesticide distribution plant for a period of 1.5 years with no reaction but then developed skin and respiratory sensitization, complete with facial edema, swelling of the hands, wheezing,

and marked vesiculation (Clayton and Clayton 1981, p. 2710). Several cases of photosensitization dermatitis have been reported among farm workers (ACGIH 1986, p. 97). A recent study in florist shop workers (Thiboutot, Hamory, and Marks 1990, in J. Am. Acad. Dermatol. 22(1):54–58) showed that at least one case of allergic dermatitis in these workers was due to captafol; this finding was confirmed by patch test.

The Agency is proposing a permissible exposure limit for captafol of 0.1 mg/m3 as an 8-hour TWA. This limit will protect workers construction. maritime, and agriculture from the significant risks of contact dermatitis, respiratory and skin irritation, and sensitization that are associated with exposure to captafol at the levels currently permitted by the absence of an OSHA limit. The Agency preliminary concludes that the proposed 8-hour TWA PEL will substantially reduce these significant risks. In addition, promulgation of these limits will make OSHA's PEL for this substance consistent across all regulated sectors. COBALT METAL, DUST, AND FUME

(measured as Co) CAS: 7440–48–4; Chemical Formula: Co H.S. No. 1100

OSHA currently has an 8-hour TWA limit of 0.1 mg/m3 for cobalt metal, dust, and fume (measured as cobalt) in the construction and maritime. There is no PEL in agriculture for these substances. The ACGIH has a TLV®-TWA of 0.05 mg/m3 for cobalt and its dust and fume; there is no NIOSH REL. The Agency is proposing a TWA PEL of 0.05 mg/m3 for cobalt metal, dust, and fume in the construction, maritime, and agriculture industries. The Agency recently established this limit for these substances in general industry, and NIOSH (Ex. 8-47, Table N1) concurred that this limit was appropriate for these sensitizers.

Cobalt is a hard, gray, magnetic, and somewhat malleable metal. It is used in steel alloys, jet engines, and in cemented carbide abrasives and tools (ACGIH 1986, p. 144).

In addition to sensitization, exposure to cobalt fume and dust causes lung disease in animals and humans. The oral LD₅₀ in rats is 6170 mg/kg, and the lowest lethal dose in rabbits by oral administration is 750 mg/kg (RTECS 1990). Instilled into the eyes of rabbits, finely divided cobalt metal caused severe irritation and abscesses of the lens, ciliary body, and retina (Grant 1986, p. 247). Animals acutely poisoned by inhalation develop pulmonary effusions, hemorrhage, and edema (HSDB 1990). Chronic inhalation of a

cobalt-metal blend at a concentration of 20 mg cobalt/m³ for 3 years caused focal fibrosis, bronchial hyperplasia, and granulomas (Clayton and Clayton 1982, p. 1612). Exposure to a 1-mg/m³ concentration of this blend for 2 years had no adverse effects (Clayton and Clayton 1982, p. 1612).

Administration of intratracheal doses (10, 25, or 50 mg) of cobalt metal dust causes obliterative bronchiolitis adenomatosis in guinea pigs (Schepers 1955/Ex. 1-365). Additional studies in animals have shown that exposure to cobalt dust or fume causes hypersensitivity reactions. Increases in serum A-2 globulin and neuraminic acid occurred in dogs and rabbits exposed by inhalation to cobalt metal, metal fume, or carbide blend; injections of cobalt chloride produced similar reactions (Stokinger and Wagner 1958/Ex. 1-381). Studies conducted in miniswine have shown that inhalation of 0.1 mg/m3 cobalt metal dust (50 percent alpha and 50 percent beta variety, with a size range of from 0.4 um to 3.6 um) has caused early (onset within 3 months) pulmonary disease. Wheezing, which indicates hypersensitivity, occurred in these animals during the fourth week of exposure to 0.1 or 1.0 mg/m3 for 6 hours/day, 5 days/week, for 3 months following a 1-week sensitizing dose (Kerfoot, Fredrick, and Domeier 1975/ Ex. 1-145).

Workers exposed to cobalt dust developed allergic sensitization dermatitis, with the most serious eruptions occurring in skin areas in contact with the dust (Clayton and Clayton 1982, p. 1616). Pulmonary disease has been reported frequently in workers exposed to cobalt in the manufacture of cemented tungsten carbide (Miller, Davis, Goldman, and Wyatts 1953/Ex. 1-40; Lundgren and Ohman 1954; Lundgren and Swenson 1953/Ex. 1-816). Chronic exposure generally causes interstitial pneumonitis, but fatalities have occasionally been reported after exposures to cobalt at concentrations of 1 to 2 mg/m³ or less (Fairhall, Castberg, Carrozzo, and Brinton 1947/Ex. 1-954; Fairhall, Keenan, and Brinton 1949/Ex. 1-479). Cobalt-cemented tungsten carbide workers exposed chronically to the dust of this substance develop pneumoconiosis, with pulmonary insufficiency (Clayton and Clayton 1982, p. 1816). An increase in serum A-2 globulin fraction was reported in the case of a welder exposed to fumes containing cobalt; the welder had a history of exertional dyspnea and an abnormal chest x-ray (Siegesmund, Funahashi, and Pintar 1974/Ex. 1-372).

Two epidemiological studies in cobalt-exposed workers have recently been published. A cohort mortality study by Mur et al. (1987) found a statistically significant increase in lung cancer mortality in cobalt and sodium workers in an electrochemical plant, and a study of hard metal workers in Great Britain (Kusaka et al. 1986) reports that occupationally-induced asthma occurred in some cobalt-exposed workers who had average exposure levels below 0.05 mg/m3. In the prior rulemaking, several commenters (Ex. 150; Tr. 7-44/7-46; Tr. 11-108) stated that pulmonary disease and ischemic heart disease may be associated with exposures to cobalt at levels of 0.06 mg/m3 and, perhaps, to levels somewhat below this concentration. In that rulemaking, OSHA expressed concern over these recent findings and stated the Agency's intention to monitor the literature on cobalt carefully to determine whether it should be included in a future PEL update project. OSHA is continuing to monitor the developing literature on cobalt; however, the primary objective of the present rulemaking is to achieve consistency in the Agency's PELs across all sectors.

Accordingly, the Agency is proposing an 8-hour TWA limit for cobalt metal, dust, and fume (measured as cobalt) of 0.05 mg/m3 in the construction, agriculture, and maritime industries. The Agency preliminarily concludes that this limit will reduce the significant risk of respiratory disease, pulmonary sensitization, and allergic dermatitis that have been demonstrated to occur at higher levels of exposure. OSHA preliminarily finds that the proposed limit is necessary to substantially reduce the risk of these material health impairments. In addition, promulgation of these limits will make OSHA's PEL for these substances consistent across all regulated sectors.

ISOPHORONE DIISOCYANATE CAS: 4098-71-9; Chemical Formula: C₁₂H₁₈N₂O₂

H.S. No. 1222 OSHA has no limit for isophorone diisocyanate (IPDI) in the construction, agriculture, and maritime industries. The 1987-1988 ACGIH TLV®-TWA for IPDI was 0.01 ppm, with a skin notation. The NIOSH REL for all diisocyanates is 0.005 ppm as a 10-hour TWA and 0.02 ppm as a 10-minute ceiling limit. The Agency is proposing PELs of 0.005 ppm as a TWA and 0.02 ppm as a STEL, and a skin notation, for IPDI. These limits were recently established by the Agency for IPDI in general industry, and NIOSH concurs (Ex. 8-47, Table N1) that these limits are appropriate.

To date, there is little direct information on the acute toxicity or health effects associated with exposure to this particular isocyanate. However, diisocyanates, in general, cause irritation of the respiratory tract, decreases in pulmonary function, and sensitization. The LCso in rats is 123 mg/ m3 for 4 hours, and the dermal LD50 in the same species is 1060 mg/kg (RTECS 1990). There are two reports of workers exposed to isophorone diisocyanate or other diisocyanates who developed asthma or dyspnea, although the airborne concentration of IPDI associated with these effects was not specified (Clarke and Aldons 1981/Ex. 1-475; Tyrer 1979/Ex. 1-396). In one case, a 50-year-old spray painter developed a severe case of asthma shortly after beginning to use an IPDIcontaining paint (Clark and Aldons 1981). This worker subsequently responded positively to a bronchial challenge (Clarke and Aldons 1981). In the other incident, painters using twopack paints, i.e., those involving a reaction between diisocvanates and polyhydroxy compounds, are reported to develop asthma from inhaling the resulting vapors (Tyrer 1979).

OSHA is proposing a 0.005-ppm 8hour TWA limit, a 0.02-ppm 15-minute short-term exposure limit, and a skin notation for IPDI in the construction, agriculture, and maritime industries. The proposed STEL of 0.02 ppm is designed to prevent the severe irritation effects associated with exposure to the diisocyanates even in nonsensitized workers, and the proposed skin notation will prevent dermal absorption of this substance. These are the limits recently established for workplaces in general industry. OSHA preliminarily concludes that these proposed limits will reduce the significant risk of immune-systemmediated pulmonary sensitization, which is associated with isocyanate exposure, among workers in construction, maritime, and agriculture.

PHENOTHIAZINE

CAS: 92-84-2; Chemical Formula: S(C₆H₄)₂NH H.S. No. 1313

OSHA currently has no occupational exposure limit for phenothiazine in the construction, agriculture, and maritime industries. The ACGIH has a TLV*_TWA of 5 mg/m³, with a skin notation; there is no NIOSH REL for this substance. The Agency is proposing a TWA PEL of 5 mg/m³, and a skin notation, for phenothiazine in the construction, agriculture, and maritime industries. OSHA recently established this limit for general industry, and

NIOSH (Ex. 8-47, Table N1) concurred with this limit in the prior rulemaking.

Phenothiazine ranges in color from grayish-green to greenish-yellow and can take the form of powder, granules, or flakes. This substance is tasteless but has a slight odor. Phenothiazine is used as an insecticide, antioxidant, polymerization inhibitor, antihelminthic agent, and as a base in the manufacture of pharmaceuticals (HSDB 1984; ACGIH 1986, p. 472). When used in pesticidal applications and in accordance with the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Exposure to phenothiazine causes moderate irritation of the skin (Cralley and Cralley 1985, p. 178). The LD₅₀ in mice is 5000 mg/kg; acutely poisoned animals showed behavioral signs (RTECS 1990). Rats given oral doses of 1250 mg/kg during days 1 through 22 of pregnancy showed adverse effects on reproduction (RTECS 1990). After pigs and cattle have been given antihelminthic doses of phenothiazine, they develop a photosensitization dermatitis with corneal edema (Grant 1986, p. 812).

A study by Mawhinney and Rakow (1968) showed that humans exposed to 15 to 48 mg/m3 of phenothiazine developed skin sensitization; symptoms of sensitization in workers included burning and itching of the skin. Accompanying these sensitization reactions were pinkish-red-colored hair and brown fingernails. Phenothiazine has also been reported to cause photosensitization of the skin, and intense irritation and itching of the skin have been associated with inhalation of phenothiazine spray (ACGIH 1986/Ex. 1-3, p. 472). Workers handling phenothiazine are reported to have developed keratitis, although whether photosensitization or physical irritation was responsible for this effect is now known (Grant 1986, p. 812). Accidental exposures to high but unspecified concentrations of phenothiazine have caused hemolytic anemia, toxic hepatitis, skin photosensitization, and pruritus (Gosselin, Smith, and Hodge 1984, p. II-238).

OSHA is proposing an 8-hour TWA PEL of 5 mg/m³, with a skin notation, for phenothiazine; this limit is below the exposure range that has been shown to cause sensitization reactions in workers. OSHA preliminarily concludes that the uncontrolled exposures that are possible in the construction, agriculture, and maritime industries in the absence of an OSHA limit potentially pose a significant risk of sensitization to workers in these sectors. The Agency believes that the proposed limit is

necessary to reduce this risk among workers in these sectors. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. p-PHENYLENE DIAMINE CAS: 106–50–3; Chemical Formula: C₆H₄(NH₂)₂ H.S. No. 2128

In general industry, construction, and maritime, OSHA's current permissible exposure limit for p-phenylene diamine is 0.1 mg/m3 as an 8-hour TWA; this limit also has a skin notation, which indicates that percutaneous absorption is a significant route of exposure for this substance. There is no limit in agriculture. The ACGIH has an 8-hour TLV®-TWA of 0.1 mg/m3 for pphenylene diamine, with a skin notation. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA PEL of 0.1 mg/m3, and a skin notation, for p-phenylene diamine in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHA-regulated

p-Phenylene diamine occurs in the form of white to light purple crystals that oxidize to purple or black on exposure to air. This substance is used as a hair dye, a photographic developer, an intermediate in the manufacture of dyes, an ingredient of antioxidants and rubber accelerators, and in photochemical measurements (ACGIH 1986, p. 474.8(89); Hawley's 1987, p. 902).

p-Phenylene diamine causes sensitization of the skin and respiratory tract in exposed workers. The oral LD50 in rats is 80mg/kg, and the lowest lethal dose in rabbits by dermal absorption is 5000mg/kg (RTECS 1990). A dose of 5000mg/kg p-phenylene diamine applied to the shaved skin of rabbits was fatal (Burnett, Loehr, and Corbett 1977, in ACGIH 1986, p. 474.8(89)). A dose of 250mg placed on the skin caused moderate irritation in rabbits and mild irritation in guinea pigs (RTECS 1990). In various species (dogs, rabbits, cats, and frogs), p-phenylene diamine was itself only slightly irritating in acute studies; however, the products of its oxidation were found to be strong skin sensitizers (Hanzlik 1923, in ACGIH 1986, p. 474). Groups of male and female rabbits were given topical treatments of 1g/kg of 1.2 percent p-phenylene diamine five times/ week for 65 applications, or 10 g per application once every 2 weeks, for a total of seven exposures. The effects observed among the animals were fissures, scab formation, desquamation, acanthosis, and moderate dermal fibroplasia (Cosmetic, Toiletry, and

Fragrance Assoc. 1969, in ACGIH 1986, p. 474.9(89)). In chronic studies in which mice, rabbits, and rats were given pphenylene diamine in various doses by various routes, there were no clinical signs or symptoms and no significant exposure-related changes as compared with controls (ACGIH 1986, p. 474.10(89)). p-Phenylene diamine has been tested for carcinogenicity in mice and rats: however, the International Agency for Research on Cancer has concluded that the evidence in animals is inadequate to evaluate p-phenylene diamine's carcinogenicity (IARC 1978, Vol. 16, p. 136). A recent study (Burnett and Goldenthal 1988, in Food Chem. Toxicol. 26(5):467-474) involving weanling rats given twice weekly skin applications of oxidative hair-coloring formulations that included p-phenylene diamine, however, has shown significant increases in mammary tumors and pituitary adenomas in treated compared with control animals.

In humans, p-phenylene diamineinduced sensitization dermatitis has been reported in workers in the furdyeing, photography, and cosmetics industries. Workers exposed to pphenylene diamine also report experiencing frequent bouts of inflammation of the pharynx and larynx and allergic asthma (Ritter 1921, in ACGIH 1986, p. 474). In reports describing the effects of accidental ingestion of hair dyes containing pphenylene diamine, symptoms reported included acute renal failure, methemoglobinemia, hemolysis, dyspnea, swelling of the lips, tongue, and neck, and muscular rhabdomyolysis (ACGIH 1986, p. 474.12(89)). Jaundice and subacute atrophy of the liver leading to death were observed in a female hairdresser who had been in contact with hair dyes for over 5 years (Israels and Susman 1934, in ACGIH 1986, p. 474.12(89)). Occupational dermatoses of allergic origin have been confirmed by patch testing in workers exposed to color-developing agents in photographic laboratories; p-phenylene diamine patch tests were positive in several of these workers (Liden, Brehmes, and Andersson 1988, in Acta Dermato-Venerologica 68(6):514-522). Twelve of 13 beauticians who developed occupational allergic contact dermatitis tested positive to patch tests with pphenylene diamine (Matsunaga, Hosokawa, Suzuki, Arima, and Hayakawa 1988, in Contact Dermatitis 18(2):94-96). Another study has confirmed the cataractogenic effects of hair dyes containing this substance (Jain et al. 1979, in ACGIH 1986, p. 474.12(89)).

Based on this evidence in humans and animals, OSHA preliminarily concludes

that p-phenylene diamine causes skin and pulmonary sensitization in exposed individuals. OSHA preliminarily finds that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that establishing the proposed 8-hour TWA limit of 0.1 mg/m³, and a skin notation, for p-phenylene diamine in agriculture is necessary to substantially reduce these risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

PHENYL GLYCIDYL ETHER
CAS: 122-60-1; Chemical Formula:
C₆H₅OCH₂CHOCH₂
H.S. No. 1315

OSHA's current 8-hour TWA limit for phenyl glycidyl ether (PGE) in the construction and maritime industries is 10 ppm. There is no PEL for PGE in agriculture. The ACGIH has a TLV*-TWA of 1 ppm for this substance; the NIOSH REL for PGE is 1 ppm as a 15-minute ceiling limit. The Agency is proposing an 8-hour TWA PEL of 1 ppm for PGE in the construction, agriculture, and maritime industries. This is the limit recently established for PGE in general industry.

Phenyl glycidyl ether is a colorless liquid that is used as a chemical intermediate, a diluent in uncured epoxy resins, and a stabilizer of halogenated compounds (ACGIH 1986, p. 476; HSDB 1986).

Exposure to PGE causes irritation of the skin and respiratory tract and sensitization of the skin in humans and animals. The oral LD50 in rats is 2150 mg/kg, and the dermal LD50 in rabbits is 1500 mg/kg (RTECS 1990). Acutely poisoned animals showed signs of central nervous system depression and died of respiratory paralysis (Smyth. Carpenter, Weil, and Pozzarin 1954/Ex. 1-440). Applied to the skin of rabbits, PGE caused moderate-to-severe irritation, and irritant effects on the eye of rabbits ranged from mild to severe (RTECS 1990). Studies by Hine, Kodama, Wellington, and colleagues (1956/Ex. 1-331) showed pulmonary inflammation and liver changes in some of the rats exposed to a 100-ppm concentration for 7 hours daily for 50 days; respiratory distress and signs of minimal eye irritation were also observed in the exposed animals. Terrill and Lee (1977/ Ex. 1-390) reported kidney, liver, spleen, thymus, and testicular changes in rats exposed to phenyl glycidyl ether at 29 ppm for 4 hours/day, 5 days/week for 2 weeks. At concentrations of 12 or 5 ppm, these authors observed no effects other

than hair loss after exposures of 6 hours/day, 5 days/week for 9 weeks; however, after 18 weeks, 10 percent of male and 25 percent of female rats exhibited alopecia (hair loss). These health effects were believed by the authors to reflect direct irritation of the skin rather than systemic absorption (Terrill and Lee 1977/Ex. 1–390).

Reports of workers using or handling phenyl glycidyl ether have described moderate skin irritation on prolonged or repeated contact. Dermatitis is common in industrially exposed workers. In a group of 20 PGE-exposed workers, 13 had serious signs of contact dermatitis: Rash with papules, second-degree burns, and edema (Hine, Kodama, Wellington et al. 1956/Ex. 1-331). In a second group of PGE-exposed workers with similar signs, eight of 15 tested positive on patch testing (NIOSH Criteria Document 1978). NIOSH (1978d/Ex. 1-232) notes that the glycidyl ethers are biologically reactive compounds because of the presence of the epoxide group; these compounds have also been shown to cause cytotoxic effects and to be mutagenic in short-term bioassays (RTECS 1990).

The Agency is proposing an 8-hour TWA PEL of 1 ppm for phenyl glycidyl ether in the construction, agriculture, and maritime industries. OSHA preliminarily concludes that this limit will protect workers in these sectors from the significant risk of skin sensitization and skin and respiratory tract irritation that is potentially associated with exposure to PGE. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. PICRIC ACID

CAS: 88-89-1; Chemical Formula: HOC₆H₂(NO₂)₃ H.S. No. 1329

OSHA's current limit for picric acid in the construction and maritime industries is 0.1 mg/m3 as an 8-hour TWA, with a skin notation. There is no PEL for picric acid in agriculture. The 1987-1988 ACGIH TLV*s for this substance were 0.1 mg/m³ as a TWA and 0.3 mg/m³ as a STEL, with a skin notation. NIOSH has no REL for picric acid but concurs (Ex. 8-47, Table N1) with the limit being proposed. The Agency is retaining its 8hour TWA PEL of 0.1 mg/m3, with a skin notation, in construction and maritime, and is proposing the same PEL for agricultural workplaces. This action will make OSHA's PEL for picric acid consistent across all industry sectors.

Picric acid occurs in the form of colorless to pale yellow, odorless, intensely bitter crystals. It is used in medicine, explosives, rocket fuels, and

matches. Picric acid also is used in the leather and glass industries and to etch copper (ACGIH 1986, p. 490).

Picric acid and its salts are toxic by ingestion, skin contact, or inhalation, and these substances also are skin sensitizers (Schwartz 1944/Ex. 1-367). The acute toxicity data for picric acid in animals are sparse. In cats, the lowest lethal oral dose is 250 mg/kg, and in rabbits this value is 120 mg/kg (RTECS 1990). Injected into the corneal stroma of the eyes of rabbits, picric acid caused injury even when the solution had been neutralized (Grant 1986, p. 737). Animals given sublethal doses of picric acid (less than or equal to 50 mg/kg) showed changes to the kidney at autopsy (NRC 1982, Vol. 4, p. 240).

Available reports concerning human exposures describe edema, papules, vesicles, and desquamations of the face, mouth, and nose caused by contact with the dust of this substance (Sunderman, Weidman, and Batson 1945/Ex. 1-383). The symptoms of systemic poisoning following skin absorption include headache, vertigo, vomiting, nausea, diarrhea, and skin and conjunctival discoloration, as well as discoloration of urine and albuminuria; high-dose exposures caused destruction of erythrocytes and produced gastroenteritis, hemorrhagic nephritis, and acute hepatitis (Sunderman, Weidman, and Batson 1945/Ex. 1-383). One worker lapsed into a coma after inhaling a high (not further specified) concentration of picric acid dust (von Oettingen 1941). Picric acid dust causes eye irritation, and sensitization dermatitis may follow dust exposure (Grant 1986, p. 737).

OSHA is retaining its 8-hour TWA PEL of 0.1 mg/m³ and the skin notation for picric acid in the construction and maritime industries and is proposing the same limit and skin notation in agriculture. The Agency preliminarily concludes that this limit is necessary to protect agricultural workers against the dermatitis and sensitization associated with occupational exposures to picric acid. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

PLATINUM (soluble salts) CAS: 7440-06-4; Chemical Formula: Pt H.S. No. 2133

In general industry, construction, and maritime, OSHA's current permissible exposure limit for the soluble platinum salts (measured as platinum) is 0.002 mg/m³ as an 8-hour TWA. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 0.002 mg/m³ for the soluble platinum salts. NIOSH has no

REL but concurs (Ex. 8–47, Table N3A) with the limit being proposed. OSHA is proposing an 8-hour TWA limit in agriculture of 0.002 mg/m³ (measured as platinum) for the soluble platinum salts. Promulgation of this limit will make the PEL for these substances consistent across all OSHA-regulated sectors.

Soluble platinum salts include substances such as sodium chloroplatinate, a yellow-orange, odorless solid; ammonium chloroplatinate, a yellow-orange solid: and platinum tetrachloride, which takes the form of brown to red crystals. Platinum's soluble salts are used as catalysts in the production of highoctane gasoline, acids, petrochemicals, pharmaceuticals, and vinyl esters, in the reclamation of platinum ore, in electroplating, and in photographic paper sensitization (NIOSH/OSHA Occupational Health Guideline 1981, p. 3; Merck 1983, pp. 80, 1235).

The soluble salts of platinum are powerful skin and respiratory allergens in humans (Klaassen, Amdur, and Doull 1986, p. 622). Exposure to the soluble platinum salts causes eye irritation and skin and pulmonary sensitization in humans. Ammonium chloroplatinate has an oral LD50 in rats of 195 mg/kg, and platinum tetrachloride has an oral LD50 in the same species of 276 mg/kg (RTECS 1989). In contact with the skin of rabbits, 100 mg of platinum tetrachloride caused severe irritation (RTECS 1989). Platinum tetrachloride caused slight, reversible irritation when the eyes of rabbits were flooded with 2 to 5 percent solutions of this substance (Grant 1986, p. 748). Acute exposure to ammonium chloroplatinate causes central nervous system effects, including convulsions and coma, before death (Clayton and Clayton 1981, p. 1861). Small non-lethal doses of this salt cause hyperirritability, restlessness, and motor excitement in experimental animals (Clayton and Clayton 1981, p. 1861). Intratesticular or subcutaneous administration of a single 26,951-µg/m3 dose of platinum tetrachloride to rats and mice caused paternal reproductive effects (RTECS 1989).

In humans, the lowest concentrations of ammonium chloroplatinate or sodium chloroplatinate reported to be toxic in humans is 900 ng/m³; at this level, coughing and cyanosis were observed (RTECS 1989). In contact with the eyes, the dusts of soluble platinum salts cause burning, lacrimation, and conjunctival hyperemia associated with photophobia (Grant 1986, p. 748). Severe contact dermatitis due to an allergic reaction may occur after repeated exposure to some platinum salts, such as ammonium

or sodium chloroplatinate or platinic chloride (Grant 1986, p. 748). Of 306 platinum refinery workers, 38 tested positive when challenged with the platinum halide salts (Murdoch et al. 1986, in Proctor, Hughes, and Fischman 1986, p. 417). Exposure to these salts is associated with a syndrome variously referred to as platinum allergy, platinum asthma, or platinosis; the signs and symptoms of platinosis include runny nose, sneezing, tightness of the chest, shortness of breath, cyanosis, wheezing, and coughing (Hunter et al. 1945; Parrot, Herbert, Saindelle, and Ruff 1969, in Proctor, Hughes, and Fischman 1988, p. 417). If exposure to the salts of platinum continues, the symptoms become progressively worse (Parmeggiani 1983, p. 1724). The earliest reported cases of platinosis occurred in 1911, when eight workers handling platinum salts experienced symptoms of throat and respiratory irritation (Karasek and Karasek 1911, in ACGIH 1986, p. 492).

Based on this evidence in humans and animals, OSHA preliminarily concludes that exposure to soluble platinum compounds causes eye irritation, skin sensitization, and asthma in exposed workers. OSHA believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse exposurerelated effects. The Agency believes that the proposed 8-hour TWA limit of 0.002 mg/m3 for the soluble salts of platinum is necessary to substantially reduce these risks of material health impairment. Promulgation of this limit will also make the PEL for these substances consistent across all OSHAregulated sectors.

RHODIUM METAL, FUME, AND INSOLUBLE COMPOUNDS CAS: 7440-16-6; Chemical Formula: Rh H.S. No. 1347

The current OSHA PEL for rhodium metal, fume, and insoluble compounds (measured as Rh) in general industry, construction, and maritime is 0.1 mg/m3 as an 8-hour TWA. There is no limit in agriculture. The ACGIH recommends a TLV*-TWA of 1 mg/m3 for rhodium metal and insoluble compounds. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limits being proposed. OSHA is proposing an 8-hour TWA limit of 0.1 mg/m3 for rhodium metal, fume, and insoluble compounds (measured as Rh) in agriculture. Promulgation of this limit will make the PEL for these substances consistent across all OSHAregulated sectors.

Rhodium metal is silvery white, hard, ductile, malleable, and odorless. It is available in metal, powder, and spongy forms. Rhodium fume is gray. Insoluble

rhodium compounds include rhodium trichloride, rhodium trioxide, and rhodium (II) acetate. Rhodium is used as an alloy with platinum, in furnace windings, laboratory crucibles, spinnerets in the rayon industry. electrical contacts, jewelry, a catalyst, and coatings (Hawley's 1987, p. 1009; ACGIH 1986, p. 512).

Rhodium is a dermal sensitizer. There are no toxicity data for rhodium metal or fume. Instilled into the eye of rabbits, rhodium trichloride caused delayed injury, with opacification and vascularization (Grant 1986, p. 887). In rhodium trichloride, the intravenous LD50 in rats and rabbits are 198 and 215 mg/kg, respectively (Landolt, Beck, and Russell 1972). Surviving rats showed no histological lesions at autopsy 100 days later (Landolt, Beck, and Russell 1972). Intravenous injection of a 60 mg/kg dose of rhodium trichloride in rats and rabbits caused no signs of systemic toxicity (Plant 1936). In a carcinogenicity bioassay in mice, rhodium trichloride was administered to mice in drinking water (5 ppm) from weaning until death (Schroeder and Mitchener 1971). The rhodium-treated mice developed a significantly increased number of malignant tumors at multiple sites (Schroeder and Mitchener 1971).

There are no reports of rhodiumrelated systemic toxicity in humans. Direct contact of the eyes with the insoluble compounds is reported to have caused a mild degree of irritation (Proctor, Hughes, and Fischman 1988, p. 433). Dermal sensitization reactions to rhodium metal have been reported in jewelry workers (Bedello, Goitre, Roncarolo, Bundino, and Cane 1987, in Contact Dermatitis 17(2):111-112) and in precious metal refinery workers (Jirasek et al. 1975, in Ceskoslovenska Dermatologie 50(6):361-368, as reported in NIOSHTIC).

Based on this evidence in humans and animals, OSHA preliminarily concludes that rhodium metal, fume, and insoluble compounds cause sensitization. OSHA therefore preliminarily concludes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing this adverse health effect. The Agency believes that an 8-hour TWA limit of 0.1 mg/m3 in agriculture is necessary to significantly reduce this risk of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for these substances consistent across all regulated sectors.

RHODIUM, SOLUBLE COMPOUNDS

CAS: 7440-16-6; Chemical Formula: Rh H.S. No. 1348

OSHA's current permissible exposure limit for the soluble rhodium compounds (measured as Rh) in general industry, construction, and maritime is an 8-hour TWA of 0.001 mg/m³. There is no limit in agriculture. The ACGIH has a TLV*-TWA of 0.01 mg/m3 for soluble rhodium compounds. NIOSH has no REL but concurs (Ex. 8-47, Table N1) with the limits being proposed. OSHA is proposing an 8-hour TWA limit of 0.001 mg/m3 for the soluble rhodium compounds in agriculture. Promulgation of this limit will make the PEL for these substances consistent across all OSHAregulated sectors.

Soluble rhodium compounds include rhodium nitrate, rhodium sulfate. rhodium carbonyl acetylacetonate, and rhodium sulfite. Soluble rhodium compounds find uses in electroplating, camera fittings, radio equipment, and jewelry, and in laboratory research (NIOSH/OSHA Occupational Health Guideline 1981, pp. 1, 3).

Rhodium is a dermal sensitizer. One of the soluble rhodium compounds. rhodium carbonyl acetylacetonate, is an eye irritant and, in contact with the skin, a sensitizer that produces delayed Type IV sensitization (Johnson, Matthey, and Co., Ltd., 1981, as cited in ACGIH 1986, p. 512). Several rhodium compounds have been found to be potent mutagens in bacterial test systems (Kanematsu, Horn, and Kada 1980, in Mutat. Res. 77(2):109-116).

Based on this evidence in humans and animals, OSHA preliminarily concludes that soluble rhodium compounds cause sensitization. OSHA therefore believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing this adverse health effect. The Agency believes that a limit of 0.001 mg/m3 for the soluble rhodium compounds (measured as Rh) in agriculture is necessary to significantly reduce the risk of this material health impairment. In addition, promulgation of this limit will make OSHA's PEL for these substances consistent across all regulated sectors.

SUBTILISINS

CAS: 9014-01-1 (Proteolytic enzymes): Chemical Formula: None H.S. No. 1373

OSHA has no occupational exposure limit for the subtilisins in the construction, agriculture, and maritime industries. The 1987-1988 ACGIH TLV* is a ceiling limit of 0.06 µg/m3. NIOSH has no REL for subtilisins but concurs (Ex. 8-47, Table N1) with the limit being proposed. The Agency is proposing a PEL for the construction, agriculture, and maritime industries of 0.06 µ g/m3

as a 60-minute STEL (measured by a high-volume sampler) for the subtilisins, which is the same PEL recently established by OSHA for the subtilisins

in general industry.

The subtilisins are proteolytic bacterial enzymes (produced by various Bacillus species) that are used primarily in laundry detergents but also in contact lens cleaners, film processing, and the food industry. They are considered a threat to occupational health because they cause immune-system-mediated bronchoconstriction and respiratory symptoms in addition to primary irritation of the skin and respiratory tract (ACGIH 1986/Ex. 1-3, p. 540; Pepys, Hargreave, Longbottom, and Faux 1969/Ex. 1-568). There are almost no acute toxicity data for subtilisins. The intravenous LD50 in mice is 75 mg/ kg (RTECS 1990). Instilled into the eyes of rabbits, subtilisins caused severe injury (RTECS 1990).

A study in monkeys (Coate, Busey, Schoenfisch, and Newmann 1978) reports the effects of exposing animals 6 hours/day, 5 days/week for 6 months to atmospheres containing synthetic detergent dust at 1, 10, or 100 mg/m³ together with enzyme (substilisins) dust at 0.001, 0.01, 0.1, or 1 mg/m³. Exposures to 10 or 100 mg/m³ detergent dust together with 0.01 or 1 mg/m³ enzyme dust produced gross signs of respiratory distress, pulmonary histopathological effects, and pulmonary function impairment in these animals (Coate et

al. 1978).

Another study (Thorne, Hillebrand, Magreni et al. 1986) reports that, in guinea pigs, the no-observed-effect level for pulmonary sensitization induced by exposure to the subtilisins for 15 minutes/day for 5 consecutive days was between 0.0083 and 0.041 mg/m³. Animals exposed on the same regimen at higher levels developed enzyme asthma (Thorne, Hillebrand, Magreni et al. 1986).

In humans, exposure to these proteolytic enzymes causes a feeling of tightness of the chest and breathlessness (Cralley and Cralley 1985, p. 469). There are several documented cases of occupational asthma in workers exposed to subtilisins (Rom 1983, p. 238). That the asthma caused by these substances is immune-system mediated is demonstrated by scratch and intradermal tests that are positive to enzyme extracts of this substance and the presence of IgE antibodies (Rom 1983, p. 239). As many as 40 to 50 percent of workers may become sensitized to subtilisins under conditions of high exposure (Rom 1983, p. 239).

Based on this evidence in humans and animals and available sampling and analytical techniques, OSHA is proposing a 60-minute STEL of 0.06 µg/ m3 for the subtilisins in the construction, agriculture, and maritime industries (using a high-volume sampler). The evidence described above indicates that a short-term limit of 0.06 µg/m3 for the subtilisins is necessary to reduce the significant risks of respiratory sensitization, skin irritation, and respiratory effects among members of the exposed worker population. OSHA preliminarily concludes that this limit will substantially reduce these significant risks. In addition, promulgation of this limit will make OSHA's PEL for the substilisins consistent across all regulated sectors. **TOLUENE-2,4-DIISOCYANATE** CAS: 584-84-9; Chemical Formula:

CH₃C₆H₃(NCO)₂ H.S. No. 1398

The current OSHA limit for toluene-2,4-diisocyanate (TDI) in the construction and maritime industries is a ceiling of 0.02 ppm. The Agency has no PEL for TDI in agriculture. The ACGIH has established TLV®s of 0.005 ppm as a TWA and 0.02 ppm as a STEL; NIOSH has RELs of 0.005 ppm as a 10-hour TWA and 0.02 ppm as a 10-minute ceiling for TDI. The Agency is proposing a PEL for TDI in the construction. agriculture, and maritime industries of 0.005 ppm as an 8-hour TWA and 0.02 ppm as a 15-minute STEL. These are the limits recently established for TDI in general industry.

Toluene-2,4-diisocyanate is a clear, colorless liquid that darkens on exposure to sunlight. It has a sharp, irritating, pungent odor. TDI is used in the manufacture of polyurethane foams, elastomers, and coatings (ACGIH 1986, p. 580; Genium MSDS 1989, No. 331).

TDI is one of the most frequently encountered occupational sensitizers, and it is also a known cross-sensitizer. In animals, TDI is a moderate to severe irritant of the skin and eyes (RTECS 1990). The oral LDso in rats is 5800 mg/ kg, and the LC50 in the same species is 14 ppm for 4 hours (RTECS 1990). In one study, guinea pigs were exposed to TDI concentrations ranging from 0.12 to 10 ppm for 3 hours/day for 5 consecutive days (Karol 1983). No animals in the low-dose group developed antibodies, but 55 percent of the animals exposed to TDI at a concentration greater than 0.36 ppm did develop specific TDI antibodies (Karol 1983). A recent National Toxicology Program lifetime bioassay involving oral gavage of rats with TDI in corn oil showed that this substance produces a statistically significant

increase in the incidence of tumors in rats of both sexes and in female mice (NTP 1986). The tumors produced included subcutaneous fibromas and fibrosarcomas, pancreatic adenomas, neoplastic nodules of the liver, and mammary gland fibroadenomas, hemangiomas, hemangiosarcomas, and hepatocellular adenomas (NTP 1986).

The proposed limit, which was recently promulgated by OSHA in general industry, is based on human data showing that some workers can develop sensitization reactions when exposed to TDI at levels below 0.02 ppm. Elkins and colleagues (1962/Ex. 1-138) reviewed the incidence of TDI intoxication in 14 plants in Massachusetts between 1957 and 1962. In eleven instances of TDI intoxication, the average concentration of TDI was 0.015 ppm, and in nine cases the average concentration was below 0.01 ppm. In all plants where the average levels were above 0.01 ppm, TDI had caused respiratory problems. TDI-related respiratory problems were not observed when the average concentration of TDI was maintained below 0.007 ppm (Elkins, McCarl, Brugsch, and Fahy 1962/Ex. 1-138).

Williamson conducted two TDI studies (1964 and 1965) that revealed a 5-percent sensitization rate in 99 workers exposed for 18 months to average TDI concentrations of below 0.02 ppm. The author believed that accidental spills accounted for the high sensitization rate seen in these workers. Williamson also found that six sensitized workers out of 18 exposed to concentrations of TDI below 0.02 ppm for 14 months showed marked decreases in lung function (Williamson 1964 and 1965).

A NOEL (no-observed-effect level) for TDI has been documented. In 1975, Roper and Cromer (Ex. 1-147) failed to observe any symptoms of respiratory illness or changes in pulmonary function in nine employees working in a plant where breathing zone samples showed TDI concentrations of 0.001 to 0.002 ppm. Wegman and colleagues (1974/Ex. 1-112; 1977/Ex. 1-171; 1982/Ex. 1-133) observed a dose-response relationship between exposure and long-term decline in lung function, and this relationship was documented by test results among TDI-exposed employees. Only for those workers exposed to less than 0.002 ppm TDI were the results of lung function tests normal (Wegman, Pagnotto, Fine, and Peters 1974/Ex. 1-112; Wegman, Peters, Pagnotto, and Fine 1977/Ex. 1-171; Wegman, Musk, Main, and Pagnotto 1982/Ex. 1-133).

In the prior rulemaking, the AFL-CIO contended that OSHA had not reduced the PEL for TDI far enough, based on the results of the Wegman et al. study.

OSHA responded to the AFL-CIO by noting that other studies in the record suggested that no effects had been seen at this level (Roper and Cromer 1975/Ex. 1–147; Elkins, McCarl, Brugsch, and Fahy 1962/Ex. 1–138). OSHA also noted that the Wegman et al. study (Ex. 1–171, p. 196) described the changes in lung function seen in workers exposed to TDI in the range of 0.002 to 0.005 ppm as "borderline."

The Agency preliminarily concludes that this evidence in humans and animals clearly demonstrates that workers in agriculture, maritime, and construction are at significant risk of pulmonary sensitization reactions, as evidenced by declines in pulmonary function observed among workers exposed to TDI concentrations below this level. OSHA believes that most of the available studies show that a 0.005 TWA PEL and 0.02 ppm STEL will protect these workers against this significant risk; only one of these studies suggests risk at levels below those being proposed. Accordingly, OSHA believes that establishing a 0.005-ppm TWA with a 0.02-ppm STEL is necessary to substantially reduce this significant risk of material health impairment. In

addition, promulgation of these limits will make OSHA's PELs for this substance consistent across all regulated sectors.

Preliminary Conclusions for This Group of Sensitizing Toxicants. For the twelve sensitizing agents included in this category of substances, OSHA preliminarily concludes that there are significant occupational risks associated with exposure. The effects caused by such exposures are mediated by the immune system and include skin sensitization, substantial decrements in lung function, bronchoconstriction, asthma, and severe skin irritation, all of which constitute material impairments of health and functional capacity. The reduced or new exposure limits being proposed for these toxic substances will substantially reduce these significant risks in workplaces in construction, maritime, and agriculture and will bring the limits for these sectors into alignment with those recently established in general industry.

14. Substances for Which Proposed Limits Are Based on Avoidance of Cancer

Introduction. For this group of substances, OSHA is proposing limits in construction, maritime, and agriculture on the basis of their potential occupational carcinogenicity. Table C14-1 lists the current OSHA
permissible exposure levels (PELs) for
these substances in construction and
maritime and the PELs being proposed
for construction, maritime, and
agricultural workplaces. The PELs being
proposed are those that are currently in
effect in general industry; adoption of
the limits being proposed would thus
make OSHA's PELs for these substances
consistent across all regulated sectors.
Table C14-1 also shows the 1987-1988
ACGIH TLV*s, NIOSH RELs, and CAS
and HS numbers for these substances.

The following discussion addresses some general aspects of carcinogenicity. together with the methodology used by OSHA in the prior air contaminants and other rulemakings to assess carcinogenic hazards. In this section, quantitative risk models that are widely accepted by the scientific community are used as a means of estimating cancer risks. The multistage model, which is the model primarily used by OSHA, is preferred by most scientists over other models because it is based on a mechanism of cancer that is believed to be biologically more plausible than is the case for the other models.

TABLE C14-1. SUBSTANCE FOR WHICH PROPOSED LIMITS ARE BASED ON AVOIDANCE OF CANCER

*OSHA's PELs do not currently apply in agriculture; OSHA's TWA limits are for 8-hour exposures; its STELs are for 15 minutes unless otherwise specified; and its ceilings are peaks not to be exceeded for any period of time.

**The ACGIH TLV*-TWA is for an 8-hour exposure; its STELs are 15-minute limits not to be exceeded more than 4 times per day with a minimum of 60 minutes between successive STEL exposures; and its ceilings are peaks not to be exceeded for any period of time. An A1 designation means that the ACGIH has designated this substance a confirmed human carcinogen; an A2 designation means that the substance is classified as a suspected human carcinogen.

***NIOSH TWA limits are for 10 hour/day, 40 hour/week exposures unless otherwise specified, and its ceilings are peaks not to be exceeded for any period of time unless a duration is specified in parentheses.

****The standard for beryllium is based on respiratory effects. In this rulemaking, OSHA has not evaluated its carcinogenicity.

*NIOSH considers this substance a potential human carcinogen and recommends that exposures be reduced to the lowest feasible concentration.

Description of the Health Effects. Cancer is an insidious and lifethreatening disease that is brought about by the invasion of organ systems by abnormal tissue growth. The abnormal tissue is comprised of cells that have been altered in such a way as to cause unrestricted cell growth. As this unrestricted growth progresses, the abnormal tissue begins to interfere with the vital functions of normal organ systems. In the absence of medical intervention, most forms of cancer are ultimately lethal. In some instances (e.g., colon cancer, breast cancer), life can be prolonged through chemotherapy, radiation treatment, surgery, or some combination of these; however, the quality of life of the victims of cancer is usually severely affected. In other instances, such as lung cancer, there is little hope of survival, even when the tumor is aggressively treated. In past rulemakings on occupational carcinogens (see, for example, Benzene, Ethylene Oxide, Asbestos, and

Formaldehyde), OSHA has held that malignant disease clearly constitutes material impairment of health and

functional capacity. An increased risk of developing cancer has been associated with occupational or environmental exposure to a number of chemical substances. The development of chemically induced cancer in humans and animals is a complex and multistep process that is not completely understood. It is currently believed that the mechanism by which cancer develops requires at least two stages: initiation and promotion. Initiation occurs when chemicals interact either directly or indirectly with DNA to cause a heritable mutation. Alterations in DNA structure may cause an incorrect reading of the DNA sequence during replication and result in more altered cells, which may eventually be expressed as a tumor. There is a correlation between substances that are mutagenic in in vitro test systems and carcinogenic in in vivo

situations. Although genotoxic assays are not capable of predicting carcinogenic potential with certainty, these assays are useful for the preliminary identification of substances that may have the potential to cause cancer.

The second stage in the carcinogenic process is promotion. Promotion is considered to be the likely mechanism of action when there is no evidence that a substance interacts with genetic material (e.g., when in vitro mutagenicity assays are negative). Peroxisome proliferation, immunosuppression, and hormonal alterations are examples of promotional events; these events facilitate the unrestricted multiplication of initiated cells, leading to the development of cancer. When a substance or its metabolite possesses both initiation and promotion capabilities, it is considered to be a complete carcinogen (i.e., exposure to the substance alone is

sufficient to cause cancer). Examples of such substances recently regulated by OSHA include asbestos, benzene, ethylene oxide, and formaldehyde.

In all of OSHA's past rulemakings for carcinogens, the Agency has used a weight-of-evidence approach to assess the carcinogenic potential of chemical substances. This approach involves examining all available human epidemiologic studies, clinical and case studies, animal studies, mutagenicity studies, and metabolic studies, and then performing a quantitative assessment of the cancer risk to determine the potential of the substance to cause cancer as a result of occupational exposure. OSHA relies heavily on epidemiologic studies of worker populations and on well-conducted animal bioassays to make these determinations. This approach to the promulgation of regulations for carcinogens has been upheld in a number of court decisions. The following discussion summarizes how human and animal studies are used to assess cancer

Epidemiology studies. Epidemiological studies that include detailed exposure data provide the best basis for establishing a causal relationship between exposure to a substance and the onset of cancer in humans. OSHA has relied heavily on epidemiologic evidence in its decisions to promulgate standards for the occupational carcinogens benzene, asbestos, and arsenic. At a minimum, positive epidemiologic studies provide qualitative proof of a causal relationship between exposure to a substance and the development of cancer in humans. A general lack of quantitative exposure data and the long latencies between onset of exposure and appearance of disease may make it difficult to derive quantitative dose-response relationships from epidemiological studies. However, the ability of such studies to link exposures to carcinogens to cancer in humans outweighs these limitations.

Because of the long latency periods associated with chemically induced cancer in humans, these studies cannot be used to detect disease until after irreparable harm has been done. To protect workers or other human populations, it is therefore necessary to assess the risks of such effects before they occur. The data used for this purpose derive from animal bioassays; these data are used to predict human responses and to infer a causal relationship between exposure to a substance and the onset of disease.

Animal data. Animal studies frequently provide the best doseresponse data for chemically induced cancer. To use these studies to predict human risk, however, researchers must make certain assumptions; the most important of these assumptions is that physiologic, pharmacokinetic, and biochemical parameters are similar among mammalian species. When data on the metabolic processes of the species of interest (e.g., rats and humans) are available, they may be used to refine the estimates of risk made by extrapolating from animals to humans. Although assumptions must be made before it is possible to use animal data to predict risk in humans, the practice of using animals as surrogates for humans in risk estimation is widely accepted throughout the scientific world. The acceptance of this methodology derives from the observation, after years of conducting thousands of bioassays, that there is a reasonable concordance between carcinogenic effects in animals and carcinogenicity in humans.

Dose-Response and Quantitative
Assessment of Risk. A large amount of
scientific evidence has accumulated
regarding the mechanisms by which
carcinogens act and the quantitative
relationship between dose and
biological response. As a result of these
investigations, several mathematical
approaches have been developed that
permit estimates to be made of the
cancer risk that is associated with
exposure to low doses of carcinogenic
substances.

Since the dominant view of the carcinogenic process holds that most cancer initiators cause irreversible damage to DNA, there is reason to assume that the dose-response of most carcinogens will follow a linear, nonthreshold relationship. The Office of Science and Technology Policy (OSTP 1985/Ex. 1-1128) recommends the use of models that incorporate low-dose linearity when the data are limited and there is uncertainty regarding the mechanisms of carcinogenic action. OSHA has observed this practice when conducting risk assessments in prior rulemakings, when the Agency generally relied on the linearized multistage model.

The multistage model used to assess cancer risks associated with exposure to substances in this group is GLOBAL83, a model developed by K.S. Crump and colleagues. If P(d) represents the lifetime risk of cancer at dose d, and A(d) is the extra risk over the background rate at dose d, then the multistage model has the following form:

 $P(d)=1-exp[-(q_1d+q_2d^2+...+q_kd^k)]$ where

 $q_i \ge 0$ i = 1, 2, 3, ..., k and A(d)=[P(d)-P(9)]/[1-P(0)]

For a unique set of q_i, this function will adequately describe (or fit) the experimentally derived data. How well the model describes the data may be mathematically determined by what are termed goodness-of-fit tests. Once the model has been fitted to the data, the maximum likelihood estimate (MLE) and the 95-percent upper-confidence limit (UCL) of A(d) are calculated using the 95-percent upper-confidence limit on parameter q_i(q_i*). The MLE is the point estimate of A(d) and is therefore considered the best estimate of extra risk at dose d.

In the prior air contaminants rulemaking, Dr. Nathan J. Karch, President of Karch Associates and an expert in risk assessment, testified on the appropriateness of using the linearized multistage model to estimate occupational cancer risk:

The multistage model and the program upon which it is based [GLOBAL83] involves a number of assumptions that are considered unlikely to underestimate risk. At lower doses, the risk is assumed to be linear in dose, and no threshold is assumed to exist.* * * The risk was assumed to be independent of background rates of cancer * * *

I recognize with growing knowledge of the complexity of various possible mechanisms for cancer induction, that several aspects of the model have come under increasing investigation * * *. Despite what may appear to be conservative assumptions in the use of animal data with the multistage model * * the multistage model is not likely to be overly conservative at most of the exposures contemplated by this rulemaking. Since the proposed PELs are similar to experimental doses in animals in many cases, the risk estimates from the multistage model tend to be less conservative unless [the PELs] are very high in relation to experimental doses. Moreover, at high doses the risk estimates produced by GLOBAL are similar to those generated by the other commonly used models (Tr. p. 13-50).

An analysis that we perform[ed on] extrapolations from animal data using the multistage model in previous OSHA rulemakings on benzene, ethylene oxide and formaldehyde disclosed that the best, meaning maximum likelihood estimates, from the multistage model were similar and not above the range of estimates from epidemiologic data available * * * [on] workers [Tr. pp. 13-52 to 13-53].

In the prior rulemaking, OSHA asked Dr. Karch to evaluate the scientific literature on the substances in this group to determine whether the data available were suitable for use with the multistage model estimate of the quantitative cancer risk of exposure to these substances. Dr. Karch found the data suitable for the following substances:

acrylamide, amitrole, carbon tetrachloride, chloroform, styrene, otoluidine, p-toluidine, and vinyl bromide (Ex. 85; Tr. p. 13–50). For the remaining substances examined by Dr. Karch in the earlier rulemaking, the data were judged not to be suitable for risk assessment purposes, and it was therefore not possible to estimate the quantitative cancer risk associated with occupational exposure to these other substances.

For those substances for which suitable data were available. OSHA quantitatively estimated the risk associated with exposure and then relied on these estimates, in part, to make significant risk findings for the air contaminants studied in general industry. OSHA has discussed its approach for making significant risk determinations for cancer-causing substances in a number of rulemakings dealing with carcinogens, and several courts of appeal have upheld OSHA's methodology. For this rulemaking, whose primary purpose is to extend the protection afforded by OSHA's generalindustry PELs to workers in construction, maritime, and agriculture, OSHA followed the same methodology as that followed in the prior air contaminants rulemaking and in other rulemakings for carcinogens. [See Arsenic, 48 FR 1816, 1901-1902 (Jan. 14, 1983), upheld ASARCO v. OSHA, 748 F.2d 483 (9th Cir., 1984); Benzene, 52 FR 34507 (September 11, 1987); Ethylene Oxide, 49 FR 25763 (June 22, 1984), Public Citizen v. Tyson, 796 F.2d 1479 (D.C. Cir., 1986); Asbestos, 51 FR 22646 (June 20, 1986), Building and Construction Trades v. Brock, 838 F.2d 1258 (D.C. Cir., 1988).]

The Supreme Court, in the Benzene decision, indicated when a reasonable person might consider a risk significant and take steps to decrease it. The Court stated:

It is the Agency's responsibility to determine in the first instance what it considers to be a "significant" risk. Some risks are plainly acceptable and others are plainly unacceptable. If, for example, the odds are one in a billion that a person will die from cancer by taking a drink of chlorinated water, the risk clearly could not be considered significant. On the other hand, if the odds are one in a thousand that regular inhalation of gasoline vapors that are 2% benzene will be fatal, a reasonable person might well consider the risk significant and take the appropriate steps to decrease or eliminate it. (I.U.D. v. A.P.I., 448 U.S. at 655).

The Court also stated that "while the Agency must support its findings that a certain level of risk exists with substantial evidence, we recognize that its determination that a particular level of risk is 'significant' wil' be based largely on policy

considerations." The Court added that the significant risk determination required by the OSH Act is "not a mathematical straitjacket," and that "OSHA is not required to support its findings with anything approaching scientific certainty." The Court ruled that "a reviewing court [is] to give OSHA some leeway where its findings must be made on the frontiers of scientific knowledge [and that * * *] the Agency is free to use conservative assumptions in interpreting the data with respect to carcinogens, risking error on the side of overprotection rather than under protection" (448 U.S. at 655, 656).

In this proposed rule, OSHA has used the general approach and guidance described above to make the preliminary significant risk determinations for the carcinogens included in this section of the proposal.

The following sections discuss the carcinogenicity evidence for the substances listed in Table C14–1. A brief discussion of the data and a quantitative risk assessment (where appropriate) are included to demonstrate the reduction in cancer risk that could result from lowering OSHA's current PELs or establishing new limits for these potential occupational carcinogens in workplaces in the construction, maritime, and agriculture industries.

ACRYLAMIDE
CAS: 79-06-1; Chemical Formula:
CH₂=CHCONH₂
H.S. No. 1008

OSHA's limit for acrylamide in the construction and maritime industries is 0.3 mg/m3 as an 8-hour TWA, with a skin notation. There is no limit for this substance in agriculture. The ACGIH considers acrylamide a suspected human carcinogen (A2) and has assigned it a TLV®-TWA of 0.03 mg/m3, with a skin notation. NIOSH has a REL of 0.3 mg/m3 as a 10-hour TWA and concurs (Ex. 8-47, Table N6A) with the limit being proposed. The Agency is proposing a TWA limit of 0.03 mg/m3. with a skin notation, for acrylamide in the construction, agriculture, and maritime industries; this is the limit recently established for this substance in general industry.

Acrylamide is a white solid that is widely used as a reactive monomer or intermediate in organic synthesis, and polyacrylamide is a polymer that is used in the manufacture of a host of products, including adhesives, mining chemicals, fibers, pharmaceuticals, animal feed, paper sizing, molded parts, textiles, and coagulant aids (American Cyanamid Company, Ex. 94; ACGIH 1986/Ex. 1–3, p. 12). Acrylamide also is used as a soil stabilizer and conditioner and in sewage and waste treatment (Grant 1986, p. 50; Hawley's 1987, p. 18).

In addition to cancer, acrylamide has caused eye and skin irritation, convulsions and other neurotoxic effects, and reproductive effects in experimental animals. The oral LDso in rats is 124 mg/kg, and the dermal LD50 in the same species is 400 mg/kg (RTECS 1990). In rabbits, the lowest lethal dermal dose is 1000 mg/kg (RTECS 1990). Applied to the eyes or skin of rabbits, acrylamide causes mild irritation (RTECS 1990). Neuropathic effects caused by exposure to acrylamide are dose-related and have been seen in rats, cats, and monkeys. Dietary dosing of cats (20 mg/kg/day) for 2 or 3 weeks caused hind-limb weakness and generalized unsteadiness (EPA 1987). Monkeys given 7.1 mg/kg/ day orally showed signs of ataxia and motor impairment after 1.5 or 2 months of exposure (EPA 1987). Acrylamide is a cumulative neurotoxin that causes peripheral neuropathy in most experimental animals when the cumulative dose reaches 10 to 50 mg/kg/ day; this substance has neuropathic effects regardless of the route of administration: oral, inhalation, intraperitoneal, or dermal (IARC 1986, p. 55). In male mice, oral administration of 35 mg/kg acrylamide twice weekly for 8 weeks caused testicular atrophy and degeneration of the germinal epithelium (IARC 1986, p. 55). A recent study (Zenick, Hope, and Smith 1986) demonstrates that acrylamide has adverse reproductive effects in both male and female rats after oral dosing. This substance also had a significant and adverse effect on the birth weight and the postpartum rate of weight gain in the offspring of treated rats (Zenick, Hope, and Smith 1986).

Two studies are available that demonstrate the carcinogenicity of acrylamide: Johnson, Gorzinsky, Bodner et al. (1986/Ex. 1–825) and Bull, Robinson, Laurie et al. (1984/Ex. 1–252). In the Bull et al. (1984/Ex. 1–252) study, acrylamide was tested as a skin tumor initiator in female Sencar mice; 12-Otetradecanoylphorbol 3-acetate (TPA) was used as a promoter.

The authors administered six doses of acrylamide that ranged from 0 to 50 mg/kg body weight over a two-week period. A significant dose-related increase in skin tumor incidence was observed for all routes of exposure tested, including topical, gastric intubation, and intraperitoneal injection. The same authors (Bull, Robinson, Laurie et al. 1984/Ex. 1-252) noted a significant dose-related increase in lung adenomas in A/J mice administered acrylamide either by gastric intubation or intraperitoneal injection.

The second study was performed by Johnson et al. (1986/Ex. 1-825) on male and female Fischer 344 rats given 0 to 2.0 mg/kg/day acrylamide in their drinking water for a period of 2 years. During the last 4 months of this study, mortality from cancer was observed at a statistically significant rate in rats exposed at the highest dose level; in addition, tumor incidence increased in animals of both sexes in the highest dose group. In females, tumors of the mammary gland, central nervous system, thyroid gland, oral tissues, uterus, and clitoral gland were seen, while males developed tumors of the central nervous system, thyroid, adrenal gland, and scrotum (Johnson, Gorzinsky, Bodner et al. 1986/Ex. 1-825). Peripheral nerve degeneration was also seen in female rats exposed at the 2-mg/kg/day level (ACGIH 1986/Ex. 1-3, p. 13).

In humans, acrylamide is a demonstrated neuropathogen. Clinical cases involving acrylamide poisoning show that the principal effects of such poisoning include: redness or peeling of the skin of the hands; excessive sweating; loss of weight; limb weakness; sensory loss in the limbs; and urinary incontinence (Le Quesne 1985). In moderate to severe cases, confusion, hallucinations, ataxia, inability to concentrate, and drowsiness occur (Le Quesne 1985). Acute exposure is likely to involve the central nervous system, while cumulative exposure to low doses of acrylamide affects the peripheral nervous system (Proctor, Hughes, and Fischman 1988, p. 56).

A mortality study of 371 acrylamide workers found no statistically significant excesses in cancers of the types hypothesized as likely on the basis of results in animals; however, the number of observed deaths for all cancers was somewhat higher than expected in this cohort (Sobel, Bond, Parsons, and Brenner 1986). A larger cohort study of acrylamide workers (Collins, Swaen, Marsh et al. 1987) found no statistically significant excess in all-cause or cause-specific mortality in these workers.

Risk estimate for acrylamide. For the EPA, Crump et al. (1987) performed a risk assessment for acrylamide, derived in part from the results of the Johnson et al. study (1986/Ex. 1–825). For the purposes of risk assessment, the data for several tumors in female rats were pooled: tumors of the mammary gland, brain and spinal cord, thyroid gland, uterus, and oral cavity. The Maximum Likelihood Estimates (MLEs) and Upper Confidence Limits (UCLs) for the current and proposed exposure limits are presented in Table C14–2. GLOBAL83, a

multistage model developed by K.S.Crump, was used to predict these risks. The risk estimate shows that, at OSHA's current PEL in construction and maritime of 0.3 mg/m³, the excess risk of death from cancer for workers exposed over their working lifetimes is 10 per 1,000 workers. At the proposed PEL of 0.03 mg/m³, this number would be reduced to 1 per 1,000 exposed workers.

TABLE C14-2.—MULTISTAGE MODEL ESTIMATES OF CANCER RISK ASSOCIATED WITH WORKING LIFETIME EXPOSURE TO ACRYLAMIDE

Exposure level	Excess cancer deaths per 1,000 workers		
	MLE	UCL	
0.3 mg/m³ *	10	45	

^a Current OSHA PEL in construction and maritime. ^b Proposed PEL and current limit in general indus-

try.

MLE = Maximum likelihood estimate of risk.

UCL = 95-percent upper-confidence limit on maximum likelihood estimate of risk.

In the prior rulemaking, a commenter representing the American Cyanamid Company, a major supplier of acrylamide, questioned OSHA's reliance on the Johnson et al. (1986/Ex. 1-825) study and the Bull et al. (1984/Ex. 1-252) study. In response to this commenter, OSHA stated (54 FR 2674, 2675) that (1) it is prudent public health policy to regulate all occupational carcinogens, and not just "complete" carcinogens, to levels that will provide worker protection; (2) the authors of the Bull et al. (1984/Ex. 1-252) study consider acrylamide to be as potent a tumor initiator as ethyl carbamate, a widely recognized tumorigen (Klaassen, Amdur, and Doull 1986/Ex. 1-99, p. 123); and (3) the Bull et al. (1984/Ex. 1-252) study is convincing evidence of acrylamide's carcinogenicity because it shows a doserelated increase in skin tumors in one strain of mouse by three different routes of exposure and the development of lung tumors in another strain of mouse by two routes of administration. OSHA notes further that the International Agency for Research on Cancer (IARC) was also convinced by the evidence presented in these studies; IARC judges the evidence for the carcinogenicity of acrylamide in animals to be sufficient (IARC 1986).

Accordingly, the Agency is proposing an 8-hour TWA PEL of 0.03 mg/m³ for acrylamide in the construction, agriculture, and maritime industries. Because acrylamide is readily absorbed through the skin and can produce

systemic effects by this exposure route, OSHA is retaining its skin notation in construction and maritime and proposing it in agriculture. The proposed PEL is based on the significant risk of cancer posed to workers occupationally exposed to this substance. The Agency preliminarily concludes that a 0.03- mg/m³ PEL, and a skin notation, will substantially reduce this significant occupational risk. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

ACRYLONITRILE

CAS: 107-13-1; Chemical Formula: CH₂—CHCN H.S. No. 2002

In general industry, construction, and maritime, OSHA's permissible exposure limits for acrylonitrile (AN) are: 2 ppm as an 8-hour TWA and 10 ppm as a 15minute short-term limit. Also, the employer shall assure that no employee is exposed to skin contact or eye contact with liquid AN. There are no limits for acrylonitrile in agriculture. A comprehensive OSHA standard for AN was promulgated on October 3, 1978 [43] FR 192). OSHA is proposing limits for AN of 2 ppm as an 8-hour TWA and 10 ppm as a 15-minute STEL in agriculture. Promulgation of these limits will make the PELs for AN consistent across all regulated sectors.

AN is a clear, colorless (when pure), or yellowish liquid with a characteristic odor. Synonyms for AN include acrylon carbaryl, cyanoethylene, fumigrain, 2-propenentrile, VCN, ventox, and vinyl cyanide. The major use of AN is in the production of acrylic and modacrylic fibers by copolymerization with other monomers such as methyl acrylate, methyl methacrylate, styrene, vinyl acetate, vinyl bromide, vinyl chloride, or vinylidene chloride, individually or in combination.

Information regarding the acute toxic effects of acrylonitrile (AN) in both humans and animals is extensive and was discussed at length in the preamble to OSHA's Emergency Temporary Standard (ETS) for AN (42 FR 2586). Based on a careful review of the evidence contained in the 1978 record, OSHA concluded at the time of that rulemaking that acrylonitrile poses a carcinogenic risk to workers. This conclusion was based on the results of experimental studies that showed an increased incidence of tumors in ANexposed animals and was supplemented by indications of an excess risk of cancer among workers exposed to AN. Moreover, AN has been shown to be capable of inducing mutations, an effect

that has also been observed for many other cancer-causing chemicals.

OSHA's determination that AN is carcinogenic is supported by the findings of other governmental agencies and scientific organizations. Based of the results of industry-sponsored animal studies, the National Cancer Institute's carcinogenicity testing program has "recognized acrylonitrile as carcinogenic to experimental animals" (Ex. 21, Docket H-108). The International Agency for Research on Cancer (IARC) of the World Health Organization stated in a draft report: * * the data indicated that acrylonitrile is carcinogenic to rats, producing tumors of the forestomach, brain, and Zymbal gland. Acrylonitrile is also embryotoxic and teratogenic" (Ex. 23, Docket H-108).

In testimony prepared for the 1978 rulemaking, the National Institute for Occupational Safety and Health (NIOSH) concluded: "AN has been shown to be a chemical carcinogen on the basis of animal experiments. The interim results which we have reviewed are significant" (Ex. 42, Docket H–108). Additional information on AN's carcinogenicity is presented in the preamble to OSHA's 1978 AN standard (43 FR 192).

Based on this evidence in humans and animals, OSHA has concluded that exposure to AN can cause cancer in humans and animals. OSHA therefore believes that, in the absence of limits, workers in agriculture are at significant risk of experiencing AN's adverse health effects. The Agency believes that the proposed limits of 2 ppm as an 8-hour TWA and 10 ppm as a 15-minute STEL are necessary to substantially reduce this significant risk of material health impairment among these workers. Promulgation of these limits will also make the PELs for this substance consistent across all OSHA-regulated sectors.

AMITROLE CAS: 61–82–5; Chemical Formula: C₂H₄N₄ H.S. No. 1620

OSHA has no PEL for amitrole in the construction, maritime, or agriculture industries. The level recommended by the ACGIH is a TLV*-TWA of 0.2 mg/m³. There is no NIOSH REL; however, NIOSH concurs (Ex. 8–47, Table N6A) with the PEL OSHA is proposing for this substance. The Agency is proposing an 8-hour TWA limit of 0.2 mg/m³ for amitrole in construction, maritime, and agriculture, which is the limit established by OSHA in the prior rulemaking for general industry.

Amitrole is a white, crystalline powder that is odorless when pure (HSDB 1985). It is used as an herbicide, a plant growth regulator, a cotton defoliant, and a reagent in photography. Amitrole's registered use as an herbicide on food crops was canceled by the EPA in 1971, and it is no longer produced in the United States (HSDB 1985; IARC 1987, p. 295; ACGIH 1986, p. 25); however, this substance is still imported into the United States for use as a specialty herbicide (brush killer) (IARC 1987, p. 295). Amitrole also continues to be used as a post-harvest herbicide around apple and pear trees and as a pre-planting herbicide for kale, maize, potatoes, wheat, and other crops (IARC 1987, p. 295). In addition, this substance is used as a roadside herbicide (IARC 1987, p. 295). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

Amitrole is a potent antithyroid agent and has been shown to cause tumors, particularly of the thyroid and pituitary glands, in experimental animals (ACGIH 1986/Ex. 1–3, p. 25). Its tumor-producing activity is thought to be related to its goitrogenic effects, which cause an increase in thyroid-stimulating hormone (TSH). Other antithyroid agents that cause TSH stimulation, such as propylthiouracil, have also been shown to produce thyroid tumors (Guyton 1981/Ex. 1–1002).

The acute toxicity of amitrole is low: The oral LD₅₀ in rats is 1100 mg/kg; in mice, this value is 14,700 mg/kg (RTECS 1990). The dermal LD₅₀ in rabbits is 10 g/kg (Clayton and Clayton 1981, p. 2702). Repeated exposure of rats to amitrole by intraperitoneal administration at doses of 1 g/kg caused inhibition of liver and kidney catalase; much lower doses (5 mg/kg) sharply reduced iodine uptake by the thyroid gland in the same species (Clayton and Clayton 1981, p. 2703).

Amitrole has been found to be carcinogenic in laboratory animals following dietary exposure to relatively high doses. Attempts to induce tumors by dermal application and subcutaneous injection have been unsuccessful. Studies investigating the carcinogenic potential of amitrole in laboratory animals are reviewed below.

The effects of lifetime exposure to amitrole were investigated in rats, mice, and hamsters fed diets containing 1, 10, or 100 ppm amitrole (Steinhoff, Weber, Mohr, and Boehme 1983/Ex. 1–208). There was a significant increase in the incidence of thyroid tumors in male and female rats and in the incidence of pituitary tumors in female rats exposed

to 100 ppm. An excess incidence of tumors was not found in male or female rats exposed to 1 or 10 ppm. The results of this experiment are presented in Table C14–3. Tumor induction was not observed in male or female mice or hamsters. Another study reported negative results for rats fed diets containing 10, 50, or 100 ppm amitrole [Jukes and Schaffer 1960/Ex. 1–213].

TABLE C14-3.—INCIDENCE OF RAT THY-ROID AND PITUITARY TUMORS ASSOCI-ATED WITH INGESTION OF AMITROLE

Tumor site	Concentration in diet (ppm)				
Tumor Site	0	1	10	100	
Thyroid (Male)					
-Benign	5/75	9/75	4/75	1 45/75	
-Malignant	3/75	0/75	3/75	1 18/75	
Thyroid (Female)		150007.51	-

Malignant	1/75	2/75	4/75	5/75	

1 p < 0.001, Fisher's Exact Test.

In contrast to the negative results obtained in mice following lifetime dietary exposure to 1, 10, or 100 ppm amitrole, positive results were observed in male and female mice following dietary exposure to higher levels (2192 ppm) of amitrole for 1 year (Innes, Ulland, Valerio et al. 1969/Ex. 1–270). Carcinomas of the thyroid were observed in 89 percent (64/72) of the exposed animals (tumor incidence in the controls was not reported).

Positive results were also observed in mice exposed to 1 percent amitrole in the diet in a lifetime study (alternating exposure for 4 weeks followed by no exposure for 1 week over the lifetime) (Feinstein, Fry, and Staffeld 1978a/Ex. 1-281). Liver tumors developed in 100 percent of the exposed mice; however, the incidence of tumors in unexposed controls was not reported. A small number of thyroid tumors was also seen in these animals. The authors hypothesized that the reason more thyroid tumors were not seen was because the animals died of the high toxic doses before such tumors could be expressed.

The Swedish National Board of Occupational Safety and Health ordered an epidemiological evaluation to assess the incidence of cancer among railroad workers exposed to herbicides (Axelson and Sundell 1974/Ex. 1–812). Amitrole was among the pesticides utilized by these workers. Cohorts were separated into groups according to whether they were exposed to amitrole and

combinations of other herbicides, phenoxy acids and combinations of other herbicides, or other herbicides alone. A statistically significant increase in the incidence of total tumors and lung tumors was found among workers exposed both to amitrole and combinations of other herbicides. Smoking frequency among members of this group was reported to be similar to the frequency of smoking in the general Swedish population.

In a 1980 follow-up to the Axelson and Sundell (1974/Ex. 1-812) study, Axelson and co-workers (Ex. 1-242) combined data from the earlier study with data on workers exposed from 1972 to 1978. Cohorts were divided into the following exposure groups: amitrole alone, phenoxy acids alone, and amitrole and phenoxy acids combined. The reanalyzed data did not show a statistically significant increase in cancer incidence among the workers exposed to amitrole alone; however, the incidence of tumors among workers exposed to amitrole and phenoxy acids together was significantly increased (Axelson, Sundell, Anderson et al. 1980/ Ex. 1-242).

Risk estimate for amitrole. The study by Steinhoff et al. (1983/Ex. 1-208) provides sufficient information to use as the basis for the quantitative estimation of the excess cancer risk associated with exposure to amitrole in the workplace. The linearized multistage model was chosen to estimate risk. The incidence of malignant thyroid tumors in female rats was used because these tumors demonstrate a clear monotonic response. Female rats were assumed to weigh 250 g and to consume 25 g of food per day. Human risks were estimated at exposure levels corresponding to the proposed PEL of 0.2 mg/m3, as well as for exposure levels of 0.4 mg/m3 and 1.0 mg/m3. The excess estimated cancer risk, in terms of excess deaths per 1,000 employees, is shown in Table C14-4.

Exposure to 0.2 mg/m³ of amitrole (the limit being proposed) over an occupational lifetime (45 years) is associated with approximately 3 excess cancer deaths per 1,000 employees (0.3 percent) if the MLE is used, and the risk at this level that corresponds to the 95-percent upper-bound estimate is about 4 excess cancer deaths per 1,000 workers. By comparison, the MLEs of risk for lifetime exposure to 0.4 mg/m³ or 1.0 mg/m³ are 5 or 13 excess deaths per 1,000 employees, respectively.

TABLE C14-4.—MULTISTAGE MODEL ES-TIMATES OF CANCER RISK ASSOCIATED WITH WORKING LIFETIME EXPOSURE TO AMITROLE

Exposure level	Excess cancer deaths per 1,000 workers		
	MLE	UCL	
0.2 mg/m³a 0.4 mg/m³	2.7	3.5	
1.0 mg/m ³	13.0	17.0	

*Proposed PEL and current limit in general indus-

try
MLE = Maximum likelihood estimate of risk.
UCL = 95-percent upper-confidence limit on maximum likelihood estimate of risk.

Some commenters in the prior rulemaking urged OSHA to use a different model, i.e., one that incorporates a threshold effect, to estimate the risk of cancer associated with exposure to amitrole (Exs. 3-894; Tr. 3-13, 3-14). Although OSHA recognizes that a threshold-effect level may exist for substances that cause cancer by acting on endocrine-sensitive tissues, the Agency points out that amitrole also has produced liver tumors in mice (Innes, Ulland, Valerio et al. 1969/Ex. 1-270; Feinstein, Frv. and Staffeld 1978a/Ex. 1-281) and, in one instance (Feinstein, Fry, and Staffeld 1978a/Ex. 1-281), the liver tumors appeared at an earlier age and at a higher incidence than did the thyroid tumors. It is not clear from the present data that the mechanism for the development of these amitrole-induced liver tumors is the same as that for amitrole-induced thyroid tumors. OSHA also notes that the proposed 0.2-mg/m3 PEL is, according to the ACGIH's calculations, only a factor of 10 lower than the demonstrated effect level for amitrole-induced effects on thyroid function. OSHA believes that the use of a tenfold uncertainty margin is reasonable when the disease in question is as serious as cancer, whether or not amitrole-induced carcinogenesis follows a dose-threshold pattern. In addition, although the human studies have not been conclusive, they do provide suggestive supporting evidence that exposure to amitrole may increase the risk of cancer among workers.

Accordingly, OSHA preliminarily concludes that the adverse effects resulting from exposure to amitrole potentially include both damage to the thyroid gland and the induction of cancer. OSHA's risk assessment, which is based on animal data, shows that this significant excess cancer risk can be substantially reduced for employees in construction, maritime, or agriculture who may currently be exposed to

amitrole at concentrations well above the proposed 0.2-mg/m³ TWA limit. Therefore, OSHA is proposing a 0.2-mg/m³ TWA exposure limit for amitrole in the construction, agriculture, and maritime industries. Promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors.

alpha-NAPHTHYLTHIOUREA (ANTU) CAS: 86–88–4; Chemical Formula: C₁₁H₁₀N₂S

H.S. No. 2009

The OSHA PEL for alphanaphthylthiourea (ANTU) in general industry, construction, and maritime is 0.3 mg/m³ as an 8-hour TWA. The Agency has no PEL for ANTU in agriculture. The ACGIH TLV*-TWA for this substance is 0.3 mg/m³. NIOSH has no REL but concurs (Ex. 8-47, Table N3A) with the limit being proposed. OSHA is proposing a 0.3-mg/m³ 8-hour TWA PEL for ANTU in agriculture. This is the same limit as the general industry PEL for ANTU.

ANTU is a colorless to gray crystalline substance that is odorless; it is used as a rodenticide, although it has not been produced in the United States for several years (HSDB 1989). When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).

ANTU is more toxic to Norway rats than to animals of other species (Hayes 1982). The lowest reported oral LD50 in rats is 6 mg/kg; in monkeys, the oral LD₅₀ is 4250 mg/kg (RTECS 1989). ANTU causes pleural effusions and pulmonary edema; before death, acutely poisoned animals had difficulty breathing and developed muscular weakness (Proctor, Hughes, and Fischman 1988, p. 79). Rats fed diets containing 50 to 800 mg/kg ANTU for 2 years showed dose-related hyperplasia of the thyroid (IARC 1983, p. 350). ANTU was tested for carcinogenicity in mice and rats, but these studies were considered inadequate for the purposes of carcinogenicity evaluation [IARC 1983,

In humans, exposure to ANTU has been associated with contact dermatitis, destructive changes in the thyroid and adrenal glands, and bladder cancer in exposed workers (ACGIH 1986, p. 36). An impurity in the ANTU, betanaphthylamine, which is a known human carcinogen, is believed to have been responsible for these cancers. In all, a total of 14 cases of urothelial tumors have been seen since 1982

among rodent exterminators who used ANTU (Orjelick 1975; Davies 1982).

There are no reported cases of accidental ANTU poisoning that have involved ANTU alone, but several poisoning incidents have been attributed to a combination of ANTU and another toxic substance. In one case, a man ingested 80 grams of a rat poison containing 30 percent ANTU and also consumed a large amount of alcohol. This individual subsequently vomited, became cyanotic, and developed fluid in his lungs; he later recovered (Hayes 1982, p. 506). Several poisoning incidents in France involved ANTU and chloralose, another pesticide; all of the poisoned individuals survived but showed tracheobronchial hypersecretions and other ANTUrelated signs (Hayes 1982, p. 506).

The evidence described above shows that ANTU causes dose-related pulmonary and endocrine effects in exposed individuals and may cause bladder cancers, although a contaminant in the ANTU, rather than ANTU itself, may have been responsible for these tumors. ANTU can cause these effects when it is ingested, inhaled, and/or

absorbed through the skin.

OSHA therefore preliminarily finds that the absence of a PEL for ANTU in agriculture places workers in this sector at significant risk of pulmonary and endocrine damage and perhaps of cancer of the urogenital tract. The Agency believes that the establishment of an 8-hour TWA PEL of 0.3 mg/m³ will substantially reduce these significant risks of material health impairment. In addition, promulgation of this limit will make OSHA's PEL for this substance consistent across all regulated sectors. ARSENIC, INORGANIC COMPOUNDS (as As)

CAS: 7440–38–2; Chemical Formula: Varies with Compound H.S. No. 2011

In general industry, construction, and maritime, OSHA's permissible exposure limit for inorganic arsenic is 10 µg/m3 averaged over an 8-hour period. There is no limit in agriculture. The ACGIH has assigned arsenic and soluble compounds a TLV*-TWA of 0.2 mg/m3. NIOSH considers these substances potential occupational carcinogens and has issued a REL of 2 µg/m3 as a 15-minute ceiling. OSHA proposes to establish a PEL of 10 µg/m3 TWA for inorganic arsenic in agriculture. Promulgation of this limit will make the PEL for this substance consistent across all OSHAregulated sectors.

Arsenic (As) is commonly present in amounts ranging from less than 0.001 percent to 6 percent of the sulfide ores mined for their copper, lead, zinc, gold, and silver content. Arsenic is also widely distributed naturally in small amounts (2–5 ppm) throughout the earth's crust. For example, it is found in iron ore and coal. Further, trace amounts of organic arsenic (less than 1 ppm) are naturally present in most living organisms, including those used for food.

Approximately 97 percent of arsenic enters end-product manufacture in the form of arsenic trioxide (As₂O₃ or "white arsenic"). This compound, which is used in the synthesis of many other arsenic compounds, is released by and obtained as a by-product of the smelting of sulfide ores of copper, lead, and zinc. Arsenic is generally regarded, however, as a troublesome impurity in these metals which is eliminated through the

smelting process.

Arsenic and its compounds have a variety of applications. The major use (comprising approximately 69 percent of U.S. consumption) is for insecticides and herbicides. Approximately 11 percent of the total U.S. arsenic trioxide consumption is used in glass production as a clarifying and reducing agent. Arsenic is also used as a defoliant in cotton harvesting. When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide

Act (FIFRA). OSHA believes that exposure to trivalent arsenic causes respiratory cancer. Studies in the copper smelting industry (Lee and Fraumeni 1969, Pinto and Enterline 1978, Rencher and Carter 1977) have shown a statistically significant increase in lung cancer mortality among workers exposed to arsenic trioxide, sulfur dioxide, and other co-contaminants released during the smelting of copper ores. As Lee and Fraumeni stated, it is impossible to differentiate in these cases between the effects of exposure to arsenic and these other co-contaminants. However, the finding that lung cancer mortality increased consistently with degree and duration of exposure to arsenic trioxide provides substantial evidence that exposure to trivalent arsenic is a cause of respiratory cancer. These data, and particularly those of Lee and Fraumeni and Pinto and Enterline, were discussed in detail in the preamble to the arsenic standard (43 FR 19584, May 5, 1978 and 48 FR 1864, January 14, 1983) and accordingly will not be repeated here. Many experts testified during the hearing for that rulemaking. Both Dr. Fraumeni (Tr. 168, Docket H-037) and Dr. Kraybill (Tr. 151, Docket H-037) stated that inorganic arsenic is strongly

incriminated as an occupational carcinogen, and NIOSH recognized that, although each epidemiological study alone has limitations, ". . . when all reports of occupational exposure to inorganic arsenic are considered together, . . it [is] undeniable that there have been carcinogenic effects which must be attributed to inorganic arsenic" (Tr. 54–5, Docket H–037). Thus, the National Cancer Institute and NIOSH both recommended that pentavalent arsenic be treated as a carcinogen.

On the other hand, the American Wood Preservers Institute (AWPI) argued in that rulemaking that the evidence was not sufficiently persuasive for OSHA to make such a determination. The AWPI suggested that pentavalent arsenic should not be implicated as a causal factor because the studies suggesting its involvement also involved exposure to trivalent arsenic. However, after a thorough review of the record as a whole, OSHA determined that the weight of the evidence clearly pointed to the carcinogenicity of pentavalent

Based on this evidence in humans, OSHA concluded in the earlier 6(b) rulemaking that exposure to inorganic arsenic causes cancer in humans. OSHA therefore believes that, in the absence of a limit, workers in agriculture who are exposed to inorganic arsenic are at significant risk of developing cancer. The Agency believes that the proposed 8-hour TWA limit of 10 µg/m3 is necessary to substantially reduce these risks of material health impairment among this group of workers. Promulgation of this limit will also make the PEL for this substance consistent across all OSHA-regulated sectors.

ASBESTOS

CAS: varies; Chemical Formula: varies H.S. No. 2013

In general industry, construction, and maritime, OSHA's permissible exposure limits for asbestos are 0.2 fiber per cubic centimeter of air (f/cc) as an 8-hour time weighted average airborne concentration and 1 f/cc as a 30-minute excursion limit. OSHA's most recent comprehensive standard for asbestos in these industries was promulgated in 1986. OSHA has no PEL for asbestos in agriculture. Therefore, OSHA is proposing to establish an 8-hour TWA PEL of 0.2 f/cc and a 30-minute excursion limit of 1 f/cc for asbestos in agriculture. Promulgation of these limits will make the PELs for asbestos consistent across all OSHA-regulated sectors.

Asbestos is the name given to a class of magnesium silicate minerals that occur in fibrous form. Minerals that are included in this group are chrysotile, crocidolite, amosite, anthophyllite asbestos, tremolite asbestos, and actinolite asbestos.

Asbestos, tremolite, anthophyllite, and actinolite have been used in the manufacture of heat-resistant clothing, automobile brake and clutch linings, and a variety of building materials (including floor tiles, roofing felts, ceiling tiles, asbestos-cement pipe and sheet, and fire-resistant drywall). Asbestos, tremolite, anthophyllite, and actinolite are also present in pipe and boiler insulation materials and in sprayed-on materials located in beams, in crawl spaces, and between walls.

OSHA is aware of no instance in which exposure to a toxic substance has more clearly demonstrated detrimental health effects on humans than asbestos exposure. The diseases caused by asbestos exposure are life-threatening or disabling; among these diseases are lung cancer, cancer of the mesothelial lining of the pleura and peritoneum. asbestosis, and gastrointestinal cancer. Of all the diseases caused by asbestos, lung cancer constitutes the greatest health risk for American asbestos workers. Lung cancer has been responsible for more than half of the excess mortality from asbestos exposure in some occupational cohorts.

The relationship between lung cancer and asbestos exposure has been established in numerous epidemiological studies of diverse groups. Asbestosinduced lung cancer usually has a latency period in excess of 20 years, and this cancer may be manifested at a younger age than is true for lung cancer victims who are not exposed to asbestos (Craighead et al., Ex. 84-033, Docket H-033). Few cases of lung cancer are curable, despite advances in medical and surgical oncology. Only 9 percent of lung cancer patients survive for 5 or more years after diagnosis (American Cancer Society, Ex. 84-160, Docket H-033). Asbestos exposure acts synergistically with cigarette smoking to multiply the risk of developing lung cancer.

Many studies also have shown conclusively that mesothelioma is associated with asbestos exposure. In some asbestos-exposed occupational groups, 10 to 18 percent of deaths have been attributable to malignant mesotheliomas of the pleura and peritoneum, a condition that is extremely rare in persons not exposed to asbestos. Generally, a latency period of at least 25 to 30 years is required hefore mesotheliomas are observed in

an occupational cohort, although some victims of mesothelioma have had latency periods exceeding 40 years (Craighead et al., Ex. 84–033, Docket H–033). This form of cancer is usually fatal within a year of diagnosis.

Some epidemiological studies of asbestos-exposed persons have shown increases in esophageal, stomach, colorectal, kidney, laryngeal, pharyngeal, and buccal cavity cancers. Although the increased risk of cancers at these sites is not as great as the increased risk of lung cancer and mesothelioma, the increase is of considerable importance because of the high background rates, and therefore the large number of victims, associated with some of these tumors in the general population. For example, a 50 percent increase in a common cancer such as colo-rectal cancer results in many more deaths than a 50 percent increase in a rare cancer.

Asbestosis is pulmonary fibrosis caused by the accumulation of asbestos fibers in the lungs. The adverse effects of asbestosis range from shortness of breath during exertion to cyanosis, effusions of serous fluid, respiratory failure, cardiac hypertrophy, and death. Asbestosis is often a progressive disease, even in the absence of continued exposure. The symptoms of the disease are shortness of breath, cough, fatigue, and vague feelings of sickness. When the fibrosis worsens, shortness of breath occurs even at rest. One clinical feature of early asbestosis as well as other lung diseases is end-respiratory crackles (rales).

Diagnosis of asbestosis is based on the presence of characteristic radiological changes, symptoms, rales, other clinical features of fibrosing lung diseases, and a history of exposure to asbestos.

Asbestos exposure can cause pleural and/or other pulmonary disease. Pleural plaques are a marker of asbestos exposure and may develop within 10 to 20 years after the initial exposure. Plaques are opaque patches visible on chest x-rays that consist of dense strands of collagen (connective tissue protein) lined by mesothelial cells. All commercially used types of asbestos induce pleural plaques. These conclusions about asbestos' health effects are widely accepted both in the U.S. and abroad, and are discussed extensively in the preamble to OSHA's 1986 standard for asbestos, which describes the evidence linking asbestos exposure to lung cancer, mesothelioma, gastrointestinal cancer, and nonmalignant respiratory diseases such as

Based on this evidence, OSHA concluded in the earlier asbestos

rulemakings that exposure to asbestos can cause cancer in humans. OSHA therefore believes that, in the absence of a PEL, workers in agriculture are at significant risk of experiencing these adverse and often life-threatening healt! effects. The Agency believes that the proposed limits of 0.2 f/cc as an 8-hour TWA and 1 f/cc as a 30-minute short term limit are necessary to substantially reduce these risks of material health impairment among this group of workers. Promulgation of these limits will make the PELs for asbestos consistent across all OSHA-regulated sectors. Although the current PELs for asbestos are 0.2 f/cc (TWA) and 1 f/cc (30-minute limit), OSHA is currently engaged in rulemaking on asbestos. If a final decision is made to lower one or both of these PELs prior to the issuance of this Air Contaminants standard, OSHA will consider adopting the new limit(s) in agriculture. OSHA requests comments on this issue from interested parties.

BENZENE

CAS No.: 71–43–2; Chemical Formula: C_6H_6

H.S. No. 2016

In general industry, construction, and maritime, OSHA's permissible exposure limits for benzene are 1 ppm as an 8-hour TWA and 5 ppm as a 15-minute STEL. OSHA's comprehensive standard for benzene was promulgated on September 11, 1987 (52 FR 176). There are no PELs for benzene in agriculture, and OSHA is therefore proposing to establish limits in that sector. Promulgation of these limits will make the PELs for benzene consistent across all OSHA-regulated sectors.

Benzene is a clear, colorless, noncorrosive, highly flammable liquid with a strong rather pleasant odor. The low boiling point and high vapor pressure of benzene causes rapid evaporation under ordinary atmospheric conditions and generates vapors that are nearly three times heavier than air.

Benzene is produced primarily by the petrochemical and petroleum refining industries by a process called catalytic reformation, which converts certain lower octane hydrocarbons into higher octane aromatics. These two industries are responsible for 98 percent of the total U.S. production of benzene. Recovery through catalytic reformation and thermal cracking of petroleum hydrocarbons, including the benzene formed from the dealkylation of toluene, accounts for approximately 75percent of the total quantity of benzene produced.

The first major industrial use of benzene was as a solvent in the rubber industry just before World War I. Large quantities of benzene are used to manufacture other organic compounds such as ethylbenzene, styrene, cumene, and cyclohexanol. This situation led to greatly increased uses of benzene as a solvent in the artificial leather, rubber goods, and rotogravure industries.

Many products contain benzene exclusively as the result of contamination. Benzene is a naturally occurring compound in crude oil and natural gas. Unreacted benzene may also be present in major benzene derivatives (e.g., methylbenzene) or in other specialty chemicals that use benzene as a feedstock (e.g., dicyclopentadiene). The presence of unreacted benzene in major derivatives or other specialty chemicals is undesirable from the producer's point of view and is not generally useful to

product users.

Industries and processes currently using benzene or liquids containing benzene include the chemical, printing, lithograph, rubber cement, rubber fabricating, paint, varnish, stain remover, adhesive, and petroleum industries. Benzene is also used extensively in chemical laboratories as a solvent and as a reactant in numerous chemical applications. Where benzene is produced, used, or stored in large amounts, it is generally contained in enclosed systems, although exposures can occur during liquid transfer operations, from equipment leakage and carryover losses, and in maintenance operations.

The scientific literature has documented hundreds of cases of leukemia, aplastic anemia, and other blood abnormalities that have been associated with benzene exposure. Epidemiologic studies of workers exposed to benzene have demonstrated significant excesses of leukemia, multiple myeloma, and lymphatic cancers as well as chromosomal aberrations in these workers. Several of these studies provide a reasonable basis for quantitative cancer risk assessment. More recently, experimental animal studies have demonstrated the induction of cancer, chromosomal damage, and bone marrow toxicity as a result of specific exposures to benzene. All of this information has been used to the extent feasible in OSHA's evaluation of the risk associated with various benzene exposure levels. Information regarding the health effects of benzene on both humans and animals was discussed at length in the preamble to OSHA's Final Rule on Occupational Exposure to Benzene (52 FR 176, September 11, 1987).

Although benzene exposure has been associated with leukemia, aplastic

anemia, multiple myeloma, various forms of lymphoma, myelofibrosis, pancytopenia, and depression of singular blood cell lines, OSHA's risk assessments were based preferentially on experimental studies involving the induction of solid tumors in mice and rats. OSHA did not include in its quantitative risk assessments risks of the other conditions mentioned above because they were for the most part identified in case reports and may have underestimated the relative risks associated with benzene exposure.

Based on the evidence in humans and animals described by OSHA in the preamble to the final 6(b) rule for benzene, OSHA concluded that exposure to benzene causes numerous adverse and potentially life-threatening health effects. OSHA therefore believes that, in the absence of a limit, workers in agriculture are at significant risk of experiencing these adverse health effects. The Agency believes that the proposed limits of 1 ppm as an 8-hour TWA and 5 ppm as a 15-minute STEL are necessary to substantially reduce these risks of material health impairment among these workers. Promulgation of these limits will also make the PEL for benzene consistent across all OSHA-regulated sectors. BERYLLIUM AND COMPOUNDS (As

CAS No.: 7440-41-7; Chemical Formula: Varies with Compound H.S. No. 1033

OSHA's current limit for beryllium and its compounds (measured as Be) in the construction and maritime industries is 0.002 mg/m^3 ($2 \mu \text{g/m}^3$) as an 8-hour TWA. There is no limit in agriculture for these substances. The ACGIH considers beryllium a suspect human carcinogen (A2) and has assigned a TLV*-TWA for beryllium and compounds of 0.002 mg/ m³ (2 μg/m³). NIOSH considers beryllium a potential human carcinogen and recommends that exposure to beryllium and compounds not exceed 0.5 μg/m³. OSHA is proposing to extend its TWA PEL of 0.002 mg/m3 (2 µg/m3) to agriculture and to add a 0.005 mg/m3 (5 μg/m³) 30-minute STEL and a 0.025 mg/ m³ (25 μg/m³) peak for beryllium and compounds in the construction, agriculture, and maritime industries. These are the limits for beryllium and its compounds currently in effect in general industry.

Beryllium is a metallic element that is hard, brittle, and grayish-white in color. It is used as a hardening agent in alloys and in non-sparking tools, drill bits, watch balance wheels, airplane brakes, electrical equipment, springs, valves, computers, gyroscopes, and in ceramics

manufacturing (Clayton and Clayton 1981, p. 1537). It also has uses in space and nuclear technologies (HSDB 1986; ACGIH 1986, p. 56).

Occupational exposure to beryllium has long been associated with the development of two distinct diseases: Acute chemical pneumonitis and chronic beryllium disease, which is a progressive and debilitating lung disease. Exposure to soluble beryllium salts and to finely divided beryllium oxide adversely affects the skin, mucous membranes, and respiratory tract and leads to chemical pneumonitis; the airborne concentrations of beryllium believed to be associated with acute pulmonary effects are on the order of $100 \mu g/m^3$ (Eisenbud et al. 1948). This form of beryllium disease has not occurred in the United States since the 1960s, in large part due to the establishment of a 25 µg/m3 30-minute short-term limit by the Atomic Energy Commission in 1949 and OSHA's adoption of this limit, through the Section 6(a) process, in 1971

Chronic beryllium disease is a systemic, granulomatous disease caused by low-level exposure to beryllium over periods ranging from several months to many years. The principal signs and symptoms of chronic beryllium disease are dyspnea, weight loss, chest pain, cough, arthralgia, and fatigue, and clinical manifestations may include interstitial crackles, liver and spleen enlargement, and, in severe cases, clubbing of the fingers. Severe cases may lead to cor pulmonole and right heart failure. Workers with chronic beryllium disease may show one or more of the following ventilatory defects: restrictive lung disease; mixed restrictive and obstructive lung disease; or diminished carbon monoxide diffusing capacity. Three stages of the disease have been identified by lung xray: A fine, diffuse granularity; a diffuse reticular pattern; and, finally, distinct

nodules (Parkes 1985).

Chronic beryllium disease results from a cell-mediated immune response of the lung to beryllium exposure. Although it had been suggested in the early 1950s that some workers appeared to be allergic to beryllium (Sterner and Eisenbud 1951), the correlation between chronic disease and sensitization to beryllium was not established until 20 years later (Deodhar et al. 1973). Advances in scientists' understanding of immunology and in techniques for the isolation and culture of lymphocytes have led to improvements in the reliability, sensitivity, and specificity of in vitro tests for beryllium sensitization. These tests involve analysis of T-cells

recovered either from the blood (Kreiss et al. 1989) or bronchoalveolar lavage fluid (Rossman et al. 1988) of individuals suspected of being sensitized.

At the time NIOSH's criteria document on beryllium was published (NIOSH 1972a), NIOSH judged the evidence that beryllium caused cancer to be equivocal. In testimony at OSHA's 1977 hearing on a standard for beryllium, however, NIOSH presented additional epidemiologic and animal evidence indicating that beryllium is carcinogenic. In particular, NIOSH (1977o; Baier 1977b/Ex. 1-831) cited the studies of Bayliss and Wagoner (1977) and Mancuso (1977), which showed significant increases in bronchogenic cancer among beryllium-exposed workers. NIOSH therefore recommended at the 1977 hearing that exposure to beryllium not exceed the reliable limit of detection of 0.5 µg/m3 (NIOSH 1977o; Baier 1977b/Ex. 1-831).

In the recent air contaminants rulemaking for general industry, OSHA determined that, because of the extensive record developed for beryllium following OSHA's 1975 proposed rule for beryllium, the issues to be resolved were too complex to address during the Air Contaminants rulemaking. Accordingly, OSHA retained the Agency's general industry PELs of 0.002 mg/m3 TWA, 0.005 mg/m3 as a 30-minute STEL, and 0.025 mg/m3 as a ceiling to provide workers with continued protection against berylliumrelated chronic lung disease. OSHA believes that, in the absence of a limit in agriculture, exposed workers are at significant risk of developing chronic beryllium disease. OSHA preliminarily concludes that extending the 0.002 mg/ m3 TWA PEL, 0.005 mg/m3 STEL, and 0.025 mg/m³ peak to construction, maritime, and agriculture will substantially reduce this risk. OSHA believes that the STEL and ceiling are necessary to aid in protecting against initial sensitization to beryllium. By analogy with the effects seen with other inorganic sensitizers such as cobalt, nickel, and chromium (Nemery 1990), short-term high exposure to antigens is believed to be associated with the development of sensitization, and OSHA believes that the STEL and ceiling will ensure that exposures are kept under strict control at all times. Promulgation of these limits in construction, maritime, and agriculture will also make the TWA, STEL, and ceiling for beryllium and its compounds consistent across all regulated sectors. CARBON TETRACHLORIDE CAS: 56-23-5; Chemical Formula: CCL H.S. No. 1073

The OSHA PEL for carbon tetrachloride in the construction and maritime industries is 10 ppm as an 8hour TWA, with a skin notation. There is no limit in agriculture. The ACGIH has established a 5-ppm TLV®-TWA limit, with a skin notation, for this substance. NIOSH considers carbon tetrachloride a potential human carcinogen and has issued a REL of 2 ppm as a ceiling limit (45 liter, 60-minute sample). However, NIOSH concurs (Ex. 8-47, Table N6A) with the limit the Agency is proposing. OSHA is proposing to delete the skin notation and to establish a PEL for carbon tetrachloride of 2 ppm as an 8-hour TWA for workplaces in the construction, agriculture, and maritime industries. This is the limit recently established for carbon tetrachloride in general industry.

Carbon tetrachloride is a heavy, mobile liquid with a sweet odor. Although carbon tetrachloride was once widely used as a dry-cleaning agent and solvent, it has now largely been replaced by less toxic substances in these uses. It is currently used in the manufacture of fluorocarbon propellants, many organic compounds, and in refrigerants and propellants (HSDB 1985).

In addition to cancer, exposure to carbon tetrachloride causes liver, kidney, and lung damage in humans and animals. The oral LD50 in rats is 2350 mg/kg, and the LC50 in the same species is 8000 ppm for 4 hours (RTECS 1990). A number of studies in experimental animals have shown that single oral doses of carbon tetrachloride ranging from about 100 to 4000 mg/kg produce fatty infiltration of the liver, loss of cytochrome P-450 and other enzymes, and histological changes in the liver (EPA 1985). Hepatocellular necrosis also may occur (EPA 1985). Rats given single oral doses of 4000 mg/kg of carbon tetrachloride showed damage to the proximal tubules of the kidney, clara cells of the lung, and endothelial lining of the lung at autopsy (EPA 1987).

In a subchronic inhalation study, guinea pigs, rats, monkeys, rabbits, and dogs exposed continuously for 90 days to a 61-mg/m³ concentration of carbon tetrachloride showed signs of liver toxicity, while animals exposed to a 6.1-mg/m³ concentration on the same regimen showed no adverse effects (Prendergast et al. 1967).

In chronic studies, rats gavaged with carbon tetrachloride at a 1 mg/kg-dose 5 days/week for 12 weeks failed to show adverse effects at autopsy, while those exposed to 10 or 33 mg/kg doses on the same regimen showed centrilobular vacuolization and necrosis of

hepatocytes at post mortem (Bruchner et al. 1986).

Human fatalities have occurred in adults who ingested as little as 1.5 ml of carbon tetrachloride, and inhalation exposure to 1500 mg/m³ has been associated with systemic poisoning and death (EPA 1985). Acute carbon tetrachloride poisoning in humans takes the following course: hepatic and renal failure, followed by pulmonary edema and cardiac failure (Rom 1983, p. 399). The following paragraphs describe the available data on carbon tetrachloride's carcinogenicity in humans and animals.

There have been three case reports in humans of liver tumors developing after carbon tetrachloride exposure (Tracy and Sherlock 1968/Ex. 1–152; Johnstone 1948/Ex. 1–817; Simler, Maurer, and Mandard 1964/Ex. 1–225). In each case, the patient had been acutely overexposed to carbon tetrachloride and had thereafter developed nausea, stomach pains, and signs of severe liver damage.

damage. Blair, Decoufle, and Grauman (1979/ Ex. 1-150) studied causes of death in 330 laundry and dry cleaning workers potentially exposed to carbon tetrachloride, as well as to trichloroethylene and tetrachloroethylene. Causes of death based on death certificates were compared to the age, sex, race, and cause-specific distribution of U.S. deaths for the same time period. The proportionate mortality ratio (PMR) for the cohort being studied for all malignant neoplasms was 128, which was statistically significant, indicating that the study group had a 28-percent higher proportion of total deaths due to cancer than the proportion in the U.S. general population. The excess cancer deaths were due to liver, lung, and

cervical cancer and leukemia. Although

the excess lung and cervical cancer

differences among these workers, the

excess liver cancer seen in this study is

deaths may reflect socioeconomic

consistent with findings in animal

studies involving carbon tetrachloride. In animals, carbon tetrachloride has produced hepatocellular carcinomas in all species evaluated (rats, mice, and hamsters). Male rats were given 47 or 94 mg/kg carbon tetrachloride and females were given 80 or 159 mg/kg by gavage for 78 weeks (NCI 1976a/Ex. 1-119; NCI 1976b/Ex. 1-168; NCI 1977b/Ex. 1-169). The incidence of hepatocellular carcinomas was increased in animals exposed to carbon tetrachloride as compared with pooled colony controls but was statistically significant only for low-dose females. The lower incidence of carcinomas in female rats at the high

dose (1/49) compared with that at the low dose (4/49) was attributed by the authors to the increased lethality that occurred among these rats before tumors could be expressed.

In this same study, mice of both sexes received 1250 or 2500 mg/kg carbon tetrachloride by gavage. Hepatocellular carcinomas were found in 49/49 lowdose and 47/48 high-dose males [compared with 5/77 in the control males) and in 40/40 low-dose and 43/45 high-dose females (compared with 1/80 in the control females) (NCI 1976a/Ex. 1-119; NCI 1976b/Ex. 1-168; NCI 1977b/ Ex. 1-169).

Edwards, Heston, and Dalton (1942/ Ex. 1-68) administered carbon tetrachloride by gavage (64 mg/mouse administered 46 times over four months) to a mouse strain known to have a low incidence of spontaneous hepatomas. The resulting incidence of hepatomas in these animals was 52 percent (28/54) for males and 32 percent (6/19) for females. Previous hepatoma incidence data for untreated mice of this strain were 2/71 for males and 0/81 for females. Carbon tetrachloride administered by gavage has also been shown to produce neoplastic changes in the livers of four additional strains of mice (Andervont 1958/Ex. 1-81; Edwards 1941/Ex. 1-86; Eschenbrenner and Miller 1943/Ex. 1-113).

Della Porta, Terracini, and Shubik (1961/Ex. 1-136) gave weekly gavage treatments of 10 to 20 µg carbon tetrachloride to hamsters for 30 weeks. and the animals were observed for an additional 25 weeks. All 10 hamsters dying or killed between weeks 43 and 55 had liver cell carcinomas, compared with 0/254 among the historical controls.

Risk estimate for carbon tetrachloride. Three animal data sets have sufficient dose-response information to allow quantitative risk estimation: The rat and mouse bioassay data (NCI 1976a/Ex. 1-119; NCI 1976b/ Ex. 1-168; NCI 1977b/Ex. 1-169) and the Edwards, Heston, and Dalton (1942/Ex. 1-68) mouse data. To increase sample sizes, the data were pooled for male and female animals in each of the three studies. The estimated risks shown in Table C14-7 are the geometric means of the risk calculated from each of the three data sets.

Inhalation risk in humans was calculated assuming an air intake of 20 m³ per 24-hour day and a 40-percent absorption rate (EPA 1984a/Ex. 1-1130). All three studies suggest that a common biological mechanism, cell death and regeneration, occurs and leads to the development of the same tumor type.

Table C14-7 presents the estimates of lifetime human risk from carbon tetrachloride exposure, calculated by the linearized multistage model (GLOBAL83) at the proposed 2-ppm limit, the ACGIH limit of 5 ppm, and the current 10-ppm OSHA PEL in construction and maritime. Both the maximum likelihood estimates (MLE) and the 95-percent upper-confidence limits of human risk are given, as well as the corresponding expected number of excess cancer deaths per 1,000 workers exposed over a working lifetime. Based on this risk estimate, the MLE at the current OSHA limit of 10 ppm is 17.9 excess deaths per 1,000 exposed workers, an estimate that clearly demonstrates a significant cancer risk at the current PEL in construction and

maritime. Risk at the current ACGIH limit of 5 ppm is estimated to be 9.2 excess deaths per 1,000 workers exposed over their working lifetimes. At the proposed limit of 2 ppm, residual risk continues to be significant, according to the Supreme Court's guidance in the Benzene decision and the analysis presented in the introduction to this section; the risk predicted at 2 ppm is 3.7 excess deaths per 1,000 workers exposed over their working lifetimes. However, risk at the 2 ppm limit is substantially reduced compared with risk at the current OSHA PEL of 10 ppm. Because of the time and resource constraints imposed by the effort to issue a generic air contaminants standard of this magnitude, OSHA did not determine further what alternative lower limit would eliminate or substantially reduce the remaining significant risk and still be feasible. OSHA will reconsider carbon tetrachloride in the next round of PEL updates. In the interim, the risk remaining at the 2 ppm limit is substantially reduced compared to the risk associated with exposure at the current OSHA PEL of 10 ppm.

Based on the evidence presented above and the quantitative estimates of carbon tetrachloride-related cancer risk, OSHA preliminarily concludes that occupational exposure to carbon tetrachloride at the former 10-ppm PEL presents a significant risk of cancer to workers in the construction and maritime industry sectors; because there is no current PEL for carbon tetrachloride in agriculture, OSHA also believes that there is a significant risk of cancer to exposed workers in that sector. OSHA's risk assessment shows the proposed limit of 2 ppm will substantially reduce this risk. Accordingly, OSHA is proposing a PEL of 2 ppm as an 8-hour TWA in construction, maritime, and agriculture. If promulgated as proposed, the permissible exposure limit for carbon tetrachloride would then be the same in all industry sectors. Because the level of residual risk at 2 ppm may be significant, OSHA is committed to reconsidering this PEL in the first update of the Air Contaminants standard. In that rulemaking, OSHA will consider a lesser PEL for all sectors. As discussed in the Legal Authorities section above, OSHA believes that this approach is necessary to provide worker protection in construction, maritime, and agriculture within a reasonable time frame and that this is an appropriate use of the Agency's authority to establish rulemaking priorities.

CHLOROFORM CAS: 67-66-3; Chemical Formula: CHCla H.S. No. 1086

The current OSHA PEL for chloroform in construction and maritime is 50 ppm as a ceiling limit. The Agency has no PEL for this substance in agriculture. The ACGIH has established a TLV*-TWA of 10 ppm and assigned chloroform an A2 (suspect human occupational carcinogen) designation. NIOSH considers chloroform a potential human carcinogen and has issued a REL for this substance of 2 ppm as a ceiling limit (45 liter, 60-minute sample); however, NIOSH concurs (Ex. 8-47, Table N6A) with the limit the Agency is proposing. OSHA is proposing a PEL for chloroform in construction, maritime, and agriculture of 2 ppm as an 8-hour TWA. This is the limit recently established for chloroform in general industry.

Chloroform is a clear, colorless, nonflammable, volatile liquid with a pleasant odor. Chloroform was one of the first inhalation anesthetics used, but its use in anesthesiology has been discontinued; the FDA has banned its use in drugs, cosmetics, and food

packaging. Chloroform is now primarily used in the synthesis of fluorocarbon 22 and other chemicals (Merck 1983, p. 301; Parmeggiani 1983, p. 463).

In addition to cancer, exposure to chloroform causes eye irritation, central nervous system depression, liver and kidney damage, and cardiac effects in humans and animals. The oral LDso in rats is 908 mg/kg, and the LCso in the same species is 75 g/m³ for 60 minutes (RTECS 1990). Acutely poisoned animals show signs of central nervous system depression, including somnolence and dyspnea; at autopsy, both liver and kidney damage are seen (Gerber and Warner 1963). Rats, rabbits, guinea pigs, and dogs exposed to 25-, 50-, or 80-ppm concentrations of chloroform for 7 hours/day, 5 days/week for 6 months showed, at autopsy, damage to the kidneys and liver (Clayton and Clayton 1982, p. 3464). In contact with the skin of rabbits for 24 hours, chloroform caused redness and a moderate degree of necrosis; the authors of this study reported that chloroform vapor also irritated the eyes of exposed animals (Torkelson, Oyen, and Rowe 1976). In addition, chloroform can be absorbed through the skin in amounts sufficient to cause systemic toxicity (weight loss, degenerative changes in the kidneys, etc.) (Torkelson, Oyen, and Rowe 1976).

In humans, exposure to a chloroform concentration of 10,000 ppm causes clinical anesthesia (Morris 1963). At higher concentrations, cardiovascular depression and ventricular defibrillation follow lethal doses in humans (Morris 1963). Workers exposed to chloroform concentrations of between 80 and 240 ppm during use of this substance as a solvent reported experiencing lassitude, gastrointestinal upsets, and mental dullness; even at a 20- to 70-ppm concentration, these workers reported similar, although milder, reactions (Challen, Hickish, and Bedfor 1958). One-quarter of the workers handling chloroform in a German chemical plant had enlarged livers in clinical examinations; these workers had been occupationally exposed to unspecified concentrations for between 1 and 4 years (Bornski, Sobolewska, and Strakowski 1967).

In the following discussion, the evidence on chloroform's carcinogenicity in humans and animals is described. It is currently believed that the carcinogenicity of chloroform results from the formation of reactive metabolites, such as phosgene, that bind to cellular macromolecules. Although there is some evidence to suggest that chloroform is weakly mutagenic, the

results of most mutagenicity tests of this substance are negative.

In humans, there are no epidemiological studies that evaluate populations exposed only to chloroform, although there are several studies that examine populations exposed to chloroform in chlorinated drinking water. However, because chloroform is not the only potential carcinogen present in chlorinated water, OSHA considers the epidemiological data inadequate to use as the basis for a quantitative risk assessment. Thus, a causal relationship between cancer and chloroform exposure cannot be determined based on epidemiological studies alone, although these studies can be used to provide general support for findings in animal studies.

A case-controlled study indicated a significant association between colon cancer and exposure to chlorinated drinking water contaminated with organic material (Young, Kanarek, and Tsiatis 1981/Ex. 1-118). Significant positive associations were also found for chloroform levels in drinking water and the incidence of mortality due to cancer of the bladder, rectum, and large intestine (Hogan, Chi, Hoel, and Mitchell 1979/Ex. 1-159). In addition, similar results have been found by others (Cantor, Hoover, Mason, and McCabe 1978/Ex. 1-50; and Gottlieb, Carr, and Morris 1981/Ex. 1-72). However, although these studies suggest an association between exposure to chloroform and an increased risk of cancer, a definite causal relationship between the development of colon and bladder cancer and exposure to chloroform cannot be determined solely from these studies.

In animals, several long-term studies provide strong evidence for the carcinogenic activity of chloroform. Chloroform has been shown to produce statistically significant increases in renal epithelial tumors in male rats and hepatocellular carcinomas in several strains of mice. The carcinogenic activity of chloroform in these studies is specific to the kidney and liver.

The carcinogenic activity of chloroform was investigated in rats exposed to chloroform by gavage for 78 weeks (NCI 1976a/Ex. 1–119). Male rats were administered doses of 90 or 180 mg/kg/day, and female rats were administered doses of 100 or 200 mg/kg/day. A statistically significant doserelated increase in renal epithelial tumors was observed in treated male rats compared with untreated, matched controls; these tumors were described as carcinomas and adenomas. No increase

in the incidence of tumors was observed in chloroform-treated female rats.

In this same study, the carcinogenicity of chloroform was evaluated in mice exposed chronically to chloroform by gavage (NCI 1976a/Ex. 1-119). Male mice were exposed to doses of 138 or 277 mg/kg/day and females to 238 or 477 mg/kg/day for 78 weeks. There were significant dose-related increases in the incidence of hepatocellular carcinomas in chloroform-treated male and female mice. The increase of tumors in male mice for low and high doses was 36 percent and 98 percent, respectively. For female mice, the increases were 80 percent for the low dose and 95 percent for the high dose of chloroform.

The carcinogenic potential of chloroform in mice was further investigated in two other studies (Roe, Palmer, and Worden 1979/Ex. 1-108; Jorgenson, Meierhenry, Rushbrook et al. 1985/Ex. 1-117). Doses of 17, 60, or 100 mg/kg/day were administered to four different strains of male and female mice (C57BL, CBA, CF/1, and ICI) by gavage for 80 weeks (Roe, Palmer, and Worden 1979/Ex. 1-108). The incidence of kidney tumors, described as hypernephromas, was significantly elevated in the ICI strain. Moderate to severe renal changes were observed in the male mice of the other strains, but no significant increase in renal tumors was reported. Tumors were not observed in female mice.

The carcinogenicity of chloroform administered in drinking water was investigated in male rats and female mice (Jorgenson, Meierhenry, Rushbrook et al. 1985/Ex. 1–117). Animals were treated with drinking water containing chloroform concentrations of 200, 400, 900, or 1800 mg/L for 104 weeks. There was a marked increase in the number of kidney tumors (described as tubular cell adenomas and adenocarcinomas) in rats. However, the incidence of tumors in female mice was not significantly increased.

Risk estimate for chloroform. The Jorgenson et al. (1985/Ex. 1-117) rat study, which demonstrated a statistically significant increase in the incidence of renal tumors in male rats, was the data set used as the basis for the quantitative risk estimation. The linearized multistage, one hit, and Weibull models were used. The maximum likelihood estimates of excess cancers over an occupational lifeti.ne for a population of 1,000 workers and the 95-percent upper-bound estimates of these risks are summarized in Table C14-8. The results obtained with the Weibull model are similar to those achieved by using the logit or probit

model. OSHA believes that the estimates based on the use of the multistage model represent the best estimates of risk. OSHA has regularly used this model in previous rulemakings because the model is considered by many to reflect a biologically plausible mechanism of carcinogenesis

The results of the data analysis presented here are similar to the results of other models described by the EPA (1984f/Ex. 1-216) for chloroform. These three models clearly demonstrate, based on the MLE estimates, that a significant cancer risk exists at the current PEL of 50 ppm. The risks estimated to exist at the current PEL are of the same order of magnitude as the risks associated with exposure to other carcinogens that OSHA has regulated (e.g., benzene, ethylene oxide). Following the approach it has used in other rulemakings, OSHA believes that the MLE estimate derived from the multistage model is the best single estimate of risk.

TABLE C14-8.-MULTISTAGE MODEL ES-TIMATES OF CANCER RISK ASSOCIATED WITH WORKING LIFETIME EXPOSURE TO CHLOROFORM

Exposure level	Excess cancer deaths per 1,000 workers			
	MLE	UCL		
Multistage:				
2 ppm ^a	0.27	1.80		
10 ppm ^b	1.90	9.00		
50 ppm ^e	22.40	46.10		
One Hit:				
2 ppm*	1.40	2.20		
10 ppm ^b	7.00	11.10		
50 ppm ^c	34.50	54.20		
Weibull:				
2 ppm ^a	0.11	0.60		
10 ppm ^b	1.60	6.30		
50 ppm ^c	24.50	51.30		

^{*} Proposed PEL in construction, maritime, and agri-

Culture.

b ACGIH TLV®.
c Current OSHA PEL in construction and maritime.

MLE = Maximum likelihood estimate of risk.

UCL = 95-percent upper-confidence limit on the maximum likelihood estimate of risk.

Based on the evidence presented above, OSHA preliminarily concludes that a significant risk of cancer exists at the current ceiling PEL of 50 ppm, with estimated risks ranging from 22 to 34 excess deaths per 1,000 workers. OSHA also believes that reducing the PEL to 2 ppm will substantially reduce this risk by from 96 to 99 percent, to a residual lifetime risk level of 0.27 to 1.40 deaths per 1,000 exposed workers. Therefore, OSHA is proposing a 2 ppm TWA PEL for chloroform in construction, maritime, and agriculture. Promulgation of this limit will also make OSHA's PEL for this substance consistent across all regulated sectors.

CHROMIC ACID, CHROMATES: ZINC CHROMATES

CAS: Varies with compound; Chemical Formula: Varies with Compound H.S. No. 1092: 1436

The current OSHA limit for chromic acid and chromates (measured as CrO₃) in the construction and maritime industries is 0.1 mg/m3 as an 8-hour TWA. The Agency has no PEL in agriculture for these substances. The ACGIH has established a TLV*-TWA of 0.05 mg/m3, measured as Cr(VI), for both the soluble and insoluble forms of chromate (except zinc chromate), and has designated insoluble chromates as confirmed human carcinogens (A1). (Note that the 0.05-mg/m3 limit, expressed as Cr(VI), approximates 0.1 mg/m3 expressed as CrO3.) NIOSH has recommended that exposure to the noncarcinogenic forms of chromium (VI) (which include chromic acid) be limited to 0.025 mg/m3 (measured as CrVI) as a 10-hour TWA and to 0.05 mg/m3 (measured as CrVI) as a 15-minute ceiling. For the carcinogenic (i.e., insoluble) forms of chromium (VI) (which include zinc chromates), NIOSH recommends a 10-hour TWA limit of 0.001 mg/m3 (measured as CrVI). OSHA is proposing a ceiling limit of 0.1 mg/m3 (measured as CrO₃) for chromic acid and chromates, as well as for zinc chromates, in the construction. agriculture, and maritime industries. This is the same PEL as the limit currently in force in general industry.

True chromic acid, H2CrO4, exists only in solution form. The chromates are normally crystalline in form, and the majority of these substances are yellowish in color. They have a wide variety of industrial uses, including metal finishing and corrosion control: production of pigments and allied products; use in leather tanning and textiles, wood preservation, and drilling muds; and in chemical synthesis (Grayson 1985, p. 279; Hawley's 1987, pp. 278, 953, 1057, and 1252).

Exposure to chromic acid mists and chromate dust may cause severe irritation of the nose, throat, bronchial tubes, and lungs. Hexavalent chromium compounds have been associated with the development of ulcerated nasal mucosa, perforated nasal septa, rhinitis, nose bleeds, perforated eardrums, pulmonary edema, asthma, kidney damage, erosion and discoloration of the teeth, and skin ulceration. Chromium compounds are known to be allergens, and exposure has been associated with the development of skin sensitization.

Evaluation of workers in the electroplating industry indicates that the current TWA PEL of 0.1 mg/m3 in

construction and maritime may not be sufficiently protective against the corrosive and irritating effects of chromates. Franchini et al. (1983, cited in Proctor, Hughes, and Fischman 1988, p. 157) found that workers exposed to chromate concentrations between 0.11 and 0.15 mg/m3 developed ulcers of the nasal septum, asthmatic bronchitis, and mucous membrane irritation. Other studies (Bloomfield and Blum 1928 and U.S. Public Health Service 1953, as cited in ACGIH 1986, p. 139/Ex. 1-3) indicate that concentrations as low as 0.06 mg/ m3 are irritating to mucous membranes. The ACGIH TLV* of 0.05 mg/m3 as an 8-hour TWA is based on protecting workers against the corrosive and irritating effects of chromates.

In the rulemaking for general industry, OSHA reviewed some of the data suggesting that exposure to certain insoluble chromate salts is associated with an elevated risk of lung cancer. OSHA determined at that time that the complex issues surrounding this evidence would be more appropriately addressed in a separate comprehensive rulemaking and is considering placing the chromates on its agenda for future rulemaking. Both the AFL-CIO (Ex. 194) and the UAW (Tr. pp. 7-65 to 7-67) agreed that this would be appropriate.

OSHA preliminarily concludes, based on the evidence presented above, that the current 0.1 mg/m3 TWA PEL in construction and maritime, and the absence of any limit for chromates in agriculture, places exposed workers at significant risk of experiencing the corrosive and irritant effects of chromates. OSHA believes that promulgation of a 0.1 mg/m3 ceiling limit will substantially reduce this risk; therefore, the Agency is proposing to apply this limit in construction, maritime, and agriculture. In addition, promulgation of this limit will make OSHA's PEL for these substances consistent across all regulated sectors.

COAL TAR PITCH VOLATILES CAS No. 65996-32-2 H.S. No. 2039

In 1967, the ACGIH adopted a TLV* of 0.2 mg/m3 for coal tar pitch volatiles (CTPV), measured as the "benzenesoluble" fraction, and listed certain of the carcinogenic components of CTPV. The TLV* was established to assist employers to minimize employee exposures to these listed carcinogenic substances-anthracene, benzo(a)pyrene (BaP), phenanthracene, acridene, chrysene, and pyrene (ACGIH 1986, p. 143). In 1970, when OSHA adopted the ACGIH limits under the Walsh-Healey Act through the OSH

Act's Section 6(a) mechanism, the TLV® for CTPV became the OSHA PEL. This PEL has been in effect in general industry and in the construction and maritime sectors since that time; however, there is no PEL for CTPV in agriculture. At this time, OSHA is proposing an 8-hour time-weighted average PEL of 0.2 mg/m³ for this substance in agricultural workplaces. Promulgation of this limit will make OSHA's PEL for CTPV consistent across all OSHA-regulated sectors.

The principal industrial sources of coal tar are coke-oven plants. The hot gases and vapors produced during the conversion of coal to coke are collected by means of a scrubber, which condenses the effluent into ammonia, water, crude tar, and other byproducts. Crude tar is separated from the remainder of the condensate for further refining and may undergo further

processing.

In a study (Aluminum Association, Inc. 1977) of aluminum industry workers, an increase in lung cancer mortality was found in potroom workers using the horizontal Soderberg process. The presence of relatively high amounts of tarry substances and BaP levels in the air of aluminum reduction plants has also been associated with increased lung cancer mortality. Doll et al. (1972) reported high respiratory cancer mortality in coke-oven workers, and Redmond et al. (1976) found that cokeoven workers employed for 5 years or more had a high risk of dying from lung and kidney cancer; non-oven workers had a high risk of developing cancers of the colon, pancreas, buccal cavity, and pharynx, while byproducts workers had no increased risk of dying from any form of cancer (Doll, Vessey, et al. 1972; Reid and Buck 1956). Based on these epidemiologic studies, OSHA preliminarily concludes that occupational exposure to crude coal tar, coal tar pitch, or mixtures containing these substances can cause lung cancer and possibly cancer at a variety of other sites, such as the colon, pancreas, buccal cavity, and pharynx.

Long-term exposure (1–43 years) to coal tar pitch has been reported to cause malignant tumors on the hands, face, and neck of briquette-factory workers (Robillard and Mouchel 1965). However, these investigators did not specify the source or chemical nature of the pitch to which the workers had been exposed. Skin tumors have been reported in many studies (Lane 1937) that involved many different samples of coal tar pitch, leading to the conclusion that coal tar pitch derived from any source should be considered a potent skin tumorigen.

OSHA's preliminary conclusion that exposure to coal tar causes lung cancer is supported by a wealth of animal data, which is discussed in detail by NIOSH (1977).

OSHA preliminarily concludes, based on the epidemiology studies briefly summarized above and on the available animal data, that the absence of any limit for coal tar pitch volatiles in agriculture places exposed workers in this sector at significant risk of developing cancer. In addition, other adverse health effects (photosensitization, respiratory effects, decreased visual acuity) have also been linked to exposure to this substance. OSHA believes that promulgation of a 0.2 mg/m3 8-hour TWA PEL will substantially reduce this risk, and the Agency is therefore proposing to apply this limit in agriculture. In addition, promulgation of this limit will make OSHA's PEL for CTPV consistent across all regulated sectors.

1,2-DIBROMO-3-CHLOROPROPANE (DBCP)

CAS: 96-12-8; Chemical Formula: C₃H₅Br₂C1 H.S. No. 2055

In general industry, construction, and maritime, OSHA's permissible exposure limit for 1,2-dibromo-3-chloropropane (DBCP) is 1 ppb (0.001 ppm) as an 8-hour TWA; this limit also has skin notation, which indicates that percutaneous absorption is a significant route of exposure for DBCP. There is no limit in agriculture. NIOSH has a REL for DBCP of 10 ppb as a 10-hour TWA. OSHA is proposing an 8-hour TWA PEL of 1 ppb (0.001 ppm), and a skin notation, for DBCP in agriculture. Promulgation of this limit will make the PEL for DBCP consistent across all OSHA-regulated sectors.

DBCP, a halogenated hydrocarbon, is produced primarily by the bromination of allyl chloride at room temperature, usually in a vigorous reaction that requires cooling. DBCP is a dense yellow or amber liquid with a pungent odor at high temperatures. It has a low vapor pressure (0.8 mm Hg at 20°C) and is slightly soluble in water (1,000 ppm).

DBCP has been used as an agricultural nematocide since 1955. DBCP is produced in the United States by Dow Chemical Company and Shell Oil company. Mexico, Japan, and Israel also manufacture DBCP and export DBCP to this country. About 12 million pounds of DBCP were consumed in 1972. Following manufacture, DBCP is shipped to formulators who reprocess the chemical into products for consumer emulsifiable concentrates, liquid concentrates, powder, granules, and

solid material. Formulating granular DBCP involves spraying liquid DBCP onto inert granules. The formulation of liquid and emulsified DBCP products usually involves the blending of technical grade DBCP with an emulsifier or solvent. The formulators may also distribute the technical grade product.

The complete distribution chain generally includes the manufacture of technical grade DBCP, transportation to the formulator, formulation of DBCP-containing pesticides, distribution of DBCP-containing pesticides, and the agricultural consumption of DBCP pesticides. When used in pesticidal applications and as directed on the label, this substance is regulated by the EPA under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA).
